The Flemish farmers are in the habit of mixing water with the urine before fermentation; this addition of water retains much of the ammonia in solution. Thus, on referring to the analysis of Sprengel, we find that when cows' urine was allowed to ferment alone for one month, 100,000 lbs. of it was found to contain 205 lbs. of ammonia; but when an equal quantity of water was added previously to fermentation, he found the liquid to contain 1622 lbs. of ammonia: this quantity, although large when compared with that retained by the undiluted urine, is not all the ammonia the urea had yielded by its decomposition, nearly 300 lbs. having escaped into the atmosphere in a gaseous form. Another disadvantage arising from the use of water to retain the ammonia, is the loss of another portion of the ammonia by volatilisation from the surface of the soil, after the application of the liquid manure, more particularly if it be applied in dry and warm weather. The expense of its application also must be greater where the ammonia is retained by water, than where it is fixed by an acid, since at least double the quantity must be conveyed on the land to produce the same effects.

Sulphate of Iron (green vitriol or copperas) is frequently used in Flanders and Holland for the purpose of converting the carbonate of ammonia of the urine into a sulphate. When sulphate of iron is added to fermented urine, the sulphuric acid, which, in the sulphate, is in combination with oxide of iron, quits the iron and combines with the ammonia of the urine, forming sulphate of ammonia, a soluble but not a volatile salt; while the iron and the carbonic acid, the latter of which was in combination with the ammonia, combine together, forming a carbonate of iron, which is insoluble and falls to the bottom of the vessel. In using sulphate of iron the formation of sulphate of ammonia is complete, provided sufficient sulphate of iron has been added to the urine. the sulphate of ammonia being a fixed salt, remains in solution, and may be thus kept for any length of time without loss. This mode of fixing the ammonia is subject to the disadvantage of leaving a sediment of carbonate of iron in the tank; which, in time, would collect to a considerable amount. If more sulphate of iron be added to the urine than sufficient to fix the ammonia, by converting it into a sulphate, it might act injuriously on vegetation in soils devoid of lime.—*Alfred Gyde, Painswick.*

ON MINERAL AND INORGANIC MANURES.

No. XXI.

BY PROFESSOR CHARLES SPRENGEL.

(*Continued from p.* 435.)

Clay and loam may be roasted immediately on their being dug out of the ground; still, the operation will succeed better if they have become somewhat dry. It may be as well to observe, that roasting should be done in the dryest and hottest season.

At times, clay or loam fit for roasting may be found in the subsoil of the field, in which case much carriage will be saved, and the ovens should be erected close at hand. It is calculated that two men can roast daily from 500 to 600 cubic feet, for which, however, two ovens will be required, of which one will be in operation whilst the other is cooling. By roasting in ovens, some fuel is saved; but the produce of roasting in heaps yields better manure, as it will be mixed with the ashes of a greater amount of fuel. It is the soil on which the loam or clay is to be used, which has to decide the duration and the degree of heating. A stiff clayey soil has not only to be manured, but also loosened by the burnt loam or clay, on which account they are to be burnt for that purpose till they have become hard, as they will then keep the soil loose like sand; still, the burning is not to be continued too long, else the whole protoxide of iron would be re-converted into ar oxide, which would cause no ammonia at all to be afterwards formed. It will not be too much for a clayey soil to use 100,000 lbs. of the burnt material on one Magdeburg acre of land; and if these contain, as is not rarely the case, 2000 lbs. protoxide of iron, 200 lbs. of ammonia can be successfully formed. Generally, however, not so much is used, as burnt clay is not a cheap manure. Clayey soils are sometimes also manured with the dust of burnt bricks; in this case, however, no ammonia can be formed, as this contains no protoxide of iron or manganese. Sandy soils, on the other hand, require a slightly roasted clay, because, as it is necessary to improve it physically as well as chemically, a strongly burnt clay would be of little avail, as it does not possess much power of retaining moisture, and cannot become well mixed with the soil. A slightly burnt clay is a better manure than one much burnt, as it contains always more protoxide of iron and manganese, besides silicates which, by having been vitrified by the heat, are easier decomposed by humic acid. It is also to be considered, that a slight roasting of clay will require much less fuel than the burning. The quantity required will be always greater than that of a clayey soil, provided that the texture of the former, as well as its composition, requires to be improved. If it is, however, merely considered as a manure, the quantity to be used will depend on its chemical ingredients. Loamy soils require the least quantity of roasted clay, as they do not need to be physically improved, but merely to receive some manuring substances. For this sort of soil, therefore, 20,000 lbs., and often even less, will be sufficient; nay, some affirm that they have produced an effect by merely applying to this sort of soil twelve times the bulk of the seed-corn; the clay used, however, in this case might be marl.

It is difficult to say how long burnt clay will act as a manure, as this depends on the quantity used, on the chemical properties of the clay, as well as those of the soil. The formation of ammonia decreases in measure as the protoxide of iron and manganese are converted into oxides, and the effect of the silicates will cease, when their bases have passed, by means of the humic acid, into the plants. Even the effects of strongly burnt clay, as a means of loosening the soil, cease finally, as it gradually assumes an earthy consistency, or becomes dissolved. Sandy soils, on the other hand, will become permanently improved by slightly roasted clay. In the first year of application, it chiefly advances the growth of the cereals, which is easily to be explained, by their receiving nitrogen through the roots, as they absorb the ammonia which is formed with the oxide of iron and manganese.

If only small quantities of roasted clay or loam are used, they are strewed over the field, and harrowed in with the seed; larger quantities are to be ploughed under, which, however, must be done very shallow, as the nitrogen of the air (indispensable for the formation of ammonia,) must always have free access. Before it is ploughed in, it is best to break it still more to pieces with both harrow and roller, because if the humic acid is to decompose the silicates, it is necessary to come into close contact with them. At times fields are manured simultaneously with roasted clay and lime, but this practice appears to me advantageous only when the soil contains much free humic acid, as otherwise the lime will expel the ammonia. The humate of ammonia which is formed, can only subsist along with lime, when the latter finds sufficient humic acid to combine with.

BRITISH OAK.

IN a book entitled the "Library of Useful and Entertaining Knowledge," in the volume which treats of timber-trees, it is said, "The Oak is the father of ships,"—the knotty Oak of England—the unwedgeable and gnarled Oak, as Shakspeare called it; in these two words describing its leading properties." Now it is evident to me that this term will only apply to Q. sessiliflora, which is more full of knots, from its habit and manner of growth, than Q. pedunculata, and which is the only kind that cannot be riven with wedges. In the same book, it is, however, added that "A writer in the 'Quarterly Review' (Sir Walter Scott) ascribes the dry rot in the Navy to the substitution of a *foreign species of Oak* in our own plantations, instead of the true native Oak." The author then goes on to acquaint his readers with what he calls "a fact long known to botanists, but of which our planters and purveyors of timber for the Navy appear to have had no suspicion," that there are two distinct species of Oaks in England—the Quercus robur, and Quercus sessiliflora, the former of which affords a close-grained, firm, solid timber, rarely subject to rot. The other more loose and sappy, very liable to rot, and not half so durable. Here the term Q. robur is applied, after the example of the late Sir James Edward Smith, to Q. pedunculata, to which the name best belongs, if the strength (robor) of the timber is considered; for according to the experience of practical men, Q. sessiliflora is the most close-grained, firm, and solid timber by far of the two. Probably Q. pedunculata, or what is here termed Q. robur, may be the best for particular parts of ships, where weight or stress is required, as from its manner of growth it is more free from knots than the "unwedgeable gnarled Oak," which without doubt is Q. sessiliflora. Thus the one may be more proper for supporting a great weight and resisting a strain; and the other, Q. sessiliflora, for not splintering by a cannon-shot, for uprights, thick planks, boards, &c. where no particular stress is laid. I say probably, for according to Mr. Atkinson, as quoted by Jack, the sessiliflora requires a greater weight to break it than the other. As to its being in solidity, firmness, and durability superior to Q. pedunculata, if cut at a proper age, I think there cannot be the least doubt, from what has been stated on former occasions; therefore they are both valuable for particular purposes.

In the same volume it is further stated that "Q. sessiliflora is supposed to have been introduced some two or three ages ago, from the Continent, where the Oaks are chiefly of the latter species, especially in the German forests, the timber of which is known to be very worthless: but what is of more importance to us to state, in fact, the imposture abounds and is propagated vigorously in the New Forest and other parts of Hampshire, in Norfolk and the northern counties, also about London, and there is too much reason to believe that the numerous complaints that were heard about our ships being infected with what was called improperly enough the dry rot were owing to the introduction of this species of Oak into the naval dock-yards, where, we understand, the distinction was not even suspected." How any writer or book-maker could pen such a passage as this is, to me, inconceivable.

Q. sessiliflora, introduced "some five or three-score ago!" Why, the most ancient Oak timber in the country, the beams of old castles, the doors of old churches, the roof of Westminster Hall, the submarine forest at Hastings, and the Oak logs taken from the mosses in Scotland, are all of that species. I have myself seen very large Oaks of the sessiliflora in the Forest of Dean and in natural Oak woods on the banks of the Derwent.

As a further specimen of the quality of the information conveyed to the public in this book of the Society for the Diffusion of Useful Knowledge, the following may be taken:—"Of the various European Oaks, the Q. pedunculata is most esteemed on the Continent; it is a magnificent tree, considerably taller than our native Oak. In the forests of Fontainebleau and Compeigne there are at this time many trees of this species, the trunks of which measure from 30 to 36 feet in circumference at the base, and rise to the height of 40 feet without a single branch. Beautiful as this species is, it produces timber very inferior to our Quercus robur—(this may arise from climate, local situation, and growing close together). It is probable that this species, which is indifferently designated by the French Botanists as Q. robur and Q. sessiliflora, is a species entirely different from our real English Oak, for the wood of the Q. pedunculata is described by these writers as harder and more compact than that of the Q. robur or sessiliflora."

The confusion and contradiction observable in the foregoing remarks is most extraordinary. The Q. pedunculata of the French is the same as the Q. pedunculata of the English; and their Q. sessiliflora is also the same species as ours: so that Q. pedunculata is in one place cried up by this writer as the true "heart of Oak" under the name of Q. robur; and then, under its other name of Q. pedunculata, it is supposed to be something else, and of bad quality. As to the concluding part of the sentence, it is wholly unintelligible. Such are the errors of writers who, having no practical or systematical knowledge of the subject on which they write, are nevertheless allowed to lead people wrong most seriously, not only in matters of opinion, but in practice.—*W. Billington.* [The above is the substance of a communication, which, in its original state, was much too long for our columns.]

ON FEEDING CATTLE IN HOUSES OR IN OPEN SHEDS.

(*Continued from page 434.*)

The functions fulfilled by the various ingredients of the food of the domestic animals, will have been seen from the foregoing imperfect sketch:—The importance of supplying matters rich in nitrogen is apparent, for without it no increase of muscular fibre can take place. Highly carbonised ingredients will, however, be seen to be no less essential, otherwise respiration will take place at the expense of the transformation of existing tissues, and in a proportionate degree with loss of condition in the animal.

The quantity of food required by carnivorous, when compared with that used by graminivorous animals, is small. The food of the former class is highly nutritive when compared with that of the latter, in addition to which, the skin of carnivorous animals is destitute of perspiratory pores, so that, in them, no consumption of food is necessary to supply waste from perspiration. Graminivorous animals, especially the ruminantia, continue eating throughout the day with little intermission, as they possess, in a greater degree, the power of converting into organised tissues the excess of food which they consume beyond what is required for supplying the waste which is constantly going forward. They therefore become plump and acquire flesh, while the carnivorous animal continues spare, its flesh being tough and sinewy. The accumulation of flesh in the latter, indeed, would be fatal to their existence, as rendering them incapable of pursuing their prey.

The conditions under which flesh and fat can be accumulated will now be understood. The extent to which this property is developed in many of the breeds of cattle in this country is truly astonishing. In the case of the stall-fed animal, deprived of all means of exercise, and preserved in an atmosphere not subject to vicissitudes of temperature, the waste of the system is inconsiderable, as compared with what it would be in the event of exercise being taken; and the consumption of nitrogenised food is accordingly greater than is required to supply the waste going forward, so that the excess here must be devoted to the production of an increase of muscular fibre or flesh. But the preservation of a high temperature and the want of exercise have also been seen to be equivalent to a diminished supply of oxygen, so that, in the circumstances under consideration, a portion of the carbon which would otherwise be consumed in respiration, will be appropriated to the production of fat, of which, it has been already stated, nitrogen is not a constituent. The proportion, too, in which either flesh or fat will be produced, can in some degree be regulated by the food, that abounding in starch, sugar, or gum, being calculated chiefly for the production of fat alone.

The foregoing sketch presents merely a brief and meagre outline of the phenomena of the process of nutrition in graminivorous animals, to which, for obvious reasons, it has been chiefly confined. Although the successful elucidation of most of these phenomena is not altogether of recent date, yet it is believed that in this department the credit due to Liebig is perhaps equal to what can be claimed for any of his predecessors. The recent work of that learned professor on the subject affords a striking earnest of what may be expected from chemical science in the interesting and important department of which it treats.

Besides, then, the connexion existing between the accumulation of flesh and fat in the domestic animals, and certain conditions as regards temperature and exercise, it is believed that the foregoing considerations are of much value in determining the relative advantages of the different methods by which the required conditions are sought to be obtained. Stall-feeding cattle is not a practice of recent introduction, nor can it be said that science has had much to do with its adoption. It has been for a length of time losing ground in certain districts, while in others it is almost entirely abandoned, and feeding in open yards, with shelter sheds, substituted, although it would appear that the propriety of the change may be gravely questioned—nay, that the practice abandoned is that which is still to be preferred. Perseverance in an erroneous practice is no new thing among an agricultural population; their disinclination to change is proverbial; but in this age of agricultural improvement it seems not a little difficult to account for the substitution of erroneous practice in the room of that which would appear to be in exact accordance with the investigations of science. But it is believed that although the practice was right, the manner of carrying it into execution may frequently have been so defective that it was rather a matter of surprise that any progress should have been made towards effecting the object in view, than that it should not have come up to the expectations of the feeder.

That the arrangements for the maintenance of the domestic animals should be such as to conduce to their comfort as much as possible is not less enjoined by the dictates of humanity than by self-interest, as, when suffering from any cause, that proficiency either in growth or fatness cannot be made, which it is so much the interest of the feeder to secure. When the animals are confined, either for the whole or the greater part of their time, the evils of even trifling inconveniences are much increased. It is no unusual thing to see stall-fed animals coming to the butcher having their knees covered by a mass of cartilage, sometimes of enormous size, caused by resting on a hard pavement. The pain endured by the unfortunate animal, in the first instance, before Nature interposed this covering for his protection, must have been great indeed. Another arrangement, frequently adopted with a view of preventing choking while feeding on Turnips, is to shorten the neck-chain by which the animal is tied, so that he cannot raise his head more than a few inches from the ground. As animals being stall-fed are seldom standing, only when taking their food, it might be supposed that tying them down in this manner could not be productive of much inconvenience; but so injurious does it often prove, that the animals may frequently be seen with the chains sunk in the backs of their necks, from their constant pressure. Deficient ventilation and want of cleanliness are also frequently characteristic of such apartments, than which nothing can be more inimical to the progress of the animals. In those districts, therefore, where the practice of stall-feeding is losing ground in the estimation of the farmers, it would be well if they made strict inquiry to ascertain that their arrangements were such as a rational and enlightened view of the animal economy would dictate.

After having seen the importance of warmth, as facilitating the object of the feeder, it may appear an anomaly to insist on ventilation; but it must be recollected that deficient ventilation is not always followed by an increase of temperature, and that the latter can be maintained with the greatest facility when the arrangements for ventilation are the most perfect. Deficient ventilation cannot be long in operation without seriously affecting the health of the animals; and it is mistaken policy to suppose that when this is the case the object of the feeder can be promoted.

The breeder and feeder of live-stock should not lose sight of the important fact that the circumstances affecting the growth and fattening of the domestic animals are widely different. The grand object is, of course, to produce the greatest effect by the smallest possible expenditure of means, whether the object be rapid growth, by which early maturity is secured, or the speedy accumulation of fat. A total want of exercise for any considerable length of time, especially in the case of growing animals, is believed to be inimical to the preservation of perfect health; but this is different from the short period of confinement to which they are subjected while being fattened off for the butcher. A certain degree of confinement may, it is conceived, be advantageously extended to cattle of every description, but total confinement in the case of young cattle and milch cows cannot be indiscriminately recommended. The practice of house-feeding milch cows has hitherto obtained but little favour, simply from the circumstance of exercise being altogether withheld; but, were an hour or two daily allotted to this purpose, very different results would be obtained.—*J. Sproule.*

Home Correspondence.

Fixation of Ammonia.—I am about to commence the formation of a manure-heap on a very extensive scale, according to the plan and directions given in your Number of the 15th ult., and shall feel greatly obliged if you, or any of your correspondents, will answer me the following queries:—Is diluted sulphuric acid still considered the best article for fixing the ammonia? What quantity of water should be used for each pound of the acid? and how many pounds of acid are sufficient for two 2-horse cart-loads, exclusive of the earth, road-side sweepings, &c. laid upon each layer of fold-manure in forming the heap? Should the diluted acid be used upon each layer, each day's work, at night? or the whole in proportion, upon the whole heap, when completed? and what are the most proper utensils to put the liquor into when using it, and the best way of doing so?—*Carl.*

[In answer to this we extract the following from a communication by Mr. Gyde, of Painswick:—"If we assume, with Boussingault, that farm-yard dung, in its ordinary or moist state, contains 0.40 in 100 of nitrogen, we shall be within a fraction of the amount contained in a mixture of 1 of litter and 3 of excrement. Hence, we shall have in 10,000 lbs. of dung 40 lbs. of nitrogen, equivalent to 48½ of ammonia, requiring 138 lbs. of liquid sulphuric acid, specific gravity 1 85, to convert it into sulphate of ammonia (that is, supposing all the nitrogen to exist in the condition of ammonia in the dung); and if, for the sake of round numbers, we calculate the 10,000 lbs. of dung at 4½ tons, we shall require a fraction over 30 lbs. of sulphuric acid per ton, to convert the ammonia into a sulphate; each ton would then be equivalent to 40 lbs. of crystallised sulphate of ammonia. The sulphuric acid should be diluted with four or five times its weight of water before it is applied to the dung, or it will undergo partial decomposition on coming in contact with the vegetable matter in the manure. Sulphate of lime (gypsum) will not do as a substitute for acid in this case, since I find that it will not fix ammonia unless it is first dissolved, and as it requires 500 times its weight of cold water for its solution, its use in that state would be quite out of the question; nevertheless, if sprinkled freely over the fold-yard, it would fix a portion, and would be a good addition to the manure. It would require 50 lbs. of gypsum to supply 30 lbs. of sulphuric acid, or to fix the ammonia in 1 ton of farm-yard dung, provided the decomposition was complete." The acid should be added every two or three days, whenever there is any considerable accumulation of fresh manure; and it must be remembered that 30 lbs. of sulphuric acid is the quantity required to fix the ammonia in manure consisting of ¼ of litter and ¾ of excrement.]

Rooks and their Owners.—It appears to me that their counsel has completely failed in making out a case in their favour (*vide* page 321). He commences by saying, "We hail with pleasure the arrival of the rooks;" and he goes on to extol their value, till at last he admits the following faults; and I think it no trifle in seed-time to the farmer to have his seed stolen by his rooks, which pull up the young blade of the Corn, on its first appearance, to get the grain. "The pilfering lasts about three weeks; we hire a boy at threepence and sixpence to scour them off. In winter they will attack the Corn-stacks." I will mention another fact to show that they will take Corn if they can possibly come at it. A short time ago a farmer took a quantity of Corn, and steeped it in arsenic, and placed it in different parts of the field, to see whether the rooks would take it or not; they soon cleared it off, and they were found dead many miles from the place where they had got it, and the man was, therefore, troubled no more with them. Rooks are not game, and the farmer has a right to destroy them, and I think it is high time that they should be destroyed; as in page 60 it appears that the expense which they occasion amounts to 4000*l.*, in a limited district, Garstang.—*Facile.* [The farmer certainly suffers considerable injury from rooks, which would destroy a good deal of his seed, and many of his Potatoe sets in spring, were he not at some expense to prevent them. The only question for consideration is—Would he not suffer to a greater degree, were these birds destroyed, by the depredations of insects, which would then undoubtedly prevail in much larger numbers?]

Thorn Planting.—The Duke of Hamilton has been making considerable improvements upon his estates in the neighbourhood of Garstang, for some years past; and, amongst other things, I have noticed the removing of the unsightly fences, and the planting them upon an entirely different system. The present year he has planted to a considerable extent. Instead of planting the Thorns upright, he lays them; those planted upright this season appear almost dead, and have made no new wood, owing, I suppose, to the dryness of the weather; while those laid have made wonderfully fine young shoots. *Facile, Garstang.*

Daniels' Manure.—Where it has been properly applied, Daniels' manure, in some instances, has been of considerable benefit; but the season has been very much against it. I am sorry to say that, in the experiments by the farmers hereabout, the manure was not half buried, and, of course, all nutriment which was exposed was soon volatilised by the sun and air. Mr. Daniels' own Wheat was excellent; but great pains was taken to bury the substance, likewise to sow the seed. He is now giving it the sixth trial on the same land. I have seen Potatoes turn out a good crop with the manure, from a very poor shallow soil, where it would not being sufficient to pay for cultivation before. It has been tried here with Potatoes, in a loamy soil—two quarters of acres on some arable land, one with stable manure, and the other with Daniels', and there was no difference in crop or flavour, but more haulm to the artificial. Indeed, when properly applied, I think it will be of great benefit to shallow uplands. It was carefully tried near this on pasture, in three different ways, with no benefit whatever. It is of no good to gardens on a loamy soil.—*T. Wharton, Weston, Bath.*

Farm-yard Manure.—Among the various experiments with manures which I am constantly reading about in your Paper, the grand result seems to be the showing how much farm-yard manure is surpassed by guano, nitrate of soda, bone-dust, &c. &c. Now what I wish to ask is, Whether, in all these experiments, poor farm

yard dung has a fair trial or no? that is, whether the dung is from a heap such as Mr. Gyde would find in his black horsepond yard, out of which all the gravy of the meat, if I may so say, has run away, or from a heap upon which all the juice has been pumped back and which has had all its ammonia fixed and been made up with all the advantages which a modern muck heap ought to receive? Because, unless it is a dung heap of such a character, I contend that it does not stand a fair comparison with the other manures Mr Gyde in his admirable papers tells us, that the urine, &c, of cattle contains all the ingredients which render guano and other manures so valuable, therefore, unless the farm yard manure is composed of all the drainage and sweepings from the stables and yard properly made up, to try it against the host of fertilisers which have all their strength concentrated and made the most of, it cannot properly be a true test of its powers Experimenters should state what sort of farm yard manure theirs is, as in 90 cases out of 100 I believe it would be found to be good of its sort, but not half so good and strong as it ought to be and is entitled to be — *R W.* [Our correspondent's complaint is a very just one the farm yard manure which is used as a standard of comparison in experiments on the value of guano, &c, is rarely what it ought to be, it is generally much the worse for having its insoluble ingredients washed out of it And there is another fault in these comparative experiments a farmer applies manure to his land perhaps once in four years, the crops of all these four years ought to be measured and weighed before the value of the manures as fertilisers can be ascertained]

Vetches —I think the practice of the father of the late Mr. Webb Hall worthy of attention even in these more enlightened days As soon as the Wheat crop was cleared, he prepared for Vetches and laid on all the manure intended for the subsequent Turnip crop, the Vetches, of course, were most luxuriant, and he was thus enabled to feed them off in good time for sowing Swedes, the land being in excellent condition, and having, moreover, the benefit derived from the increased quantity of manure from the sheep, in consequence of the superiority of the crop of Vetches —*Luso*

Smut in Wheat —About 40 or 50 years ago a Mr Roger Treffry, of Beer Alston, professed to be in possession of a secret for preventing the smut in Wheat Accordingly, about seed time he made a tour of several of the midland counties, offering to sow seed from the most infected sample, but prepared by him, also he would take the cleanest seed, which he also prepared these were both sown, and next year at harvest he called on those farmers who permitted him to try the experiment; when, if the smutted seed was found to produce [illegible] their respective merits and cost

We have seen that the urine of man and our domestic animals contains a substance [illegible] receive three guineas for the secret this he did, as I understood, without an exception, and realised a very handsome sum. His secret for disinfection consisted simply in thorough washing in pure water, and on the other hand, he infected the good seed by thoroughly rubbing it with the contents of smut balls. After all, his method was not generally adopted, nor do I believe it certain of success without extreme care. I once prepared the seed for a field by well washing in two waters, and skimming off the light corn which floated, and yet the crop was more than half smutty I am of opinion that heat is necessary to destroy the vegetative power of the sporules, and therefore adopted the following plan which was perfectly successful, for I was never after troubled with smut. I placed the seed intended for the next day's sowing in a heap, upon the top of this was a vessel of boiling saturated solution of common salt, into which was thrown a sufficient quantity of fresh burnt lime, the slaking of which raised the temperature far above that of boiling water, and it foamed most furiously over the vessel, and ran down amongst the Wheat, the whole was then carefully turned over several times, till thoroughly mixed the heap dressed up neatly, and left till morning, when it was quite dry enough to drill — *Luso*.

Wide Drilling.—In your Leading Article, p 413, you invite the communication of the experience of your readers on this subject. I am therefore induced to mention an experiment I tried, "long long ago" I planted two acres of a very rich garden loam with Wheat, one acre was dibbled in 3-feet rows, and 9 inches from hole to hole, with 2 corns in each; the other at 18 inches, and 9 inches from hole to hole. The plants grew very luxuriantly, but never covered the ground, the ears were very long and loose, and the sample thin and hungry * I have no memorandum of the product, but I considered the attempt to give Wheat so much room a complete failure. Adjoining these two acres I drilled two other acres at 16-inch intervals, which produced 70 bushels of very good Wheat.—*Luso*.

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND

A Monthly Council was held at the Society's House, in Hanover square on Wednesday last, the 3rd of July present—His Grace the Duke of Richmond, K.G., in the chair; Marquess of Downshire, Earl Beauchamp, Viscount Torrington, Lord Cameys, Lord Hatherton, Col. Austen, Thomas Raymond Barker, Esq; John R. Barker, Esq., Geo. R. Barker, Esq; J Bennett, Esq., M.P; S. Bennett, Esq, T W Bramston, Esq., M.P., W. R Browne, Esq; F Burke, Esq., Col Challoner; F. C. Cherry, Esq.; R. Colman, Esq, E. D. Davenport, Esq.; J. H H. Foley, Esq, Capt. Forbes, R.N; B. Gibbs, Esq, W. Fisher Hobbs, Esq; Sir John Johnstone, Bt, M P, Rev. R. C. Kyone, J. Kinder, Esq; Sir F Lawley, Bt, Sir C. Lemon, Bt., M.P; Col. Macdonall, J W L Naper, Esq., Sir R. Price, Bt; W. Shaw, Esq W. R. C. Stansfield, Esq., M P., and V. Stuckey, Esq

Viscount Alford, of Carlton Terrace, London, and Ralph Creyke, Esq, of Rawcliffe Hall, near Selby, Yorkshire, were elected Governors, and the following gentlemen Members of the Society:—

Pilgrim Charles H Kingsfield, Southampton
Pilgrim Charles Kingsfield, Southampton
Bevdon Rev Frederick North Stoneham Rectory, Southampton
Bearmark Richard, Mount St Alban's, Caerleon, Monmouthshire
Streeter William Sanderstead Croydon Surrey
Carson William Seaforth near Liverpool
Prosser George Llvaston Farm Harewood Ross, Herefordshire
Crouch John Cirencester Gloucestershire
Mitford Charles Pittshill Petworth Sussex
Butler Hon Sir Edward Chilworth Southampton
Altherly George junr Southampton

Huddleston Thomas Stedcomb House Colleton Devon

The names of 18 candidates for election at the next meeting were then read

FINANCES —Mr Raymond Barker, Chairman of the Finance Committee, laid before the Council the Monthly Report of the Committee on the state of the Funds of the Society, from which it appeared, that at the end of last month the amount of invested capital was 7700*l*, and the current cash balance in the hands of the bankers' at the same date 345*l* 7*s* Mr Barker explained to the Council that this balance included 800*l*, on account of the Southampton subscription, of which the Committee had recommended a further sum of 500*l* to the sulphate of ammonia being a fixed salt remains in solution and may be thus kept for any length of time be paid to meet the expenses already incurred in making the requisite preparations for the ensuing country meeting at that place, leaving 200*l* of the subscription of 1000*l* originally remitted from Southampton still remaining in the bankers hands, and available for further claims on that account

Colonel Challoner, Captain Forbes, and Mr Bennett M P, and Mr S Bennett, favoured the Council with the results of their trials to effect the extirpation of rats from their respective premises, Colonel Challoner taking that opportunity of correcting a misapprehension of his statement at a former meeting as to the extent of his experience of Mr Meyer's preparations. At that time, his application of those preparations had been limited to a broad Holly-hedge in his flower garden, where they were found to be perfectly successful —Mr Manning, contractor of the Society's works at Southampton, addressed a letter to the President in reference to the site of the Pavilion, Messrs. Drummond, of Stirling, and Messrs Morton, of Edinburgh, replied to the inquiries of the Council on the subject of Bixby's draught machine. The Rev C J James, of Braintree Rectory, called the attention of the Council to the condition of agricultural labourers, and the intentions of the Committee appointed to report to the Council on that subject, and the Highland and Agricultural Society of Scotland announced the reservation of tickets for members of the Royal Agricultural Societies of England and Ireland who might be induced to attend the ensuing meeting at Glasgow The Marquis of Downshire invited the attendance of members at the ensuing meeting of the Royal Agricultural Improvement Society of Ireland at Dublin, where the authorities were prepared to receive them with every attention Mr Brandreth Gibbs presented copies of the Prize Sheet of the December Show of the Smithfield Club

The Council then adjourned to Wednesday next, the 10th of July

HIGHLAND AND AGRICULTURAL SOCIETY.

At a late meeting of Committee, for making the necessary arrangements for the ensuing great Agricultural Meeting at Glasgow, the following Report was read — The local Committee, upon their appointment in January, 1843, commenced operations by taking steps to unite the adjoining counties of Lanark, Renfrew, Dumbarton, Ayr, Argyll, Bute, and Stirling, in constituting the Show, and are happy to state that all these counties agreed to combine for the purpose, with the exception of Stirlingshire, which declined to have any connexion with the Show The local Committee have given their best endeavours to frame a list of premiums to be awarded for stock, which should be properly adapted to the different breeds deserving encouragement in the districts comporing the Show, and they hope that the list which has been published, which was drawn up with the aid and under the superintendence of the Edinburgh Committee, will afford satisfaction. The premiums advertised amount to 1575*l*, being the largest sum ever offered for competition at any of the Society's Shows; and it is expected that the number and liberality of the premiums will attract an unprecedented display of stock from all parts of the country. The requisite funds are not yet fully realised, but with a little exertion there is no doubt of the sum subscribed being perfectly sufficient to meet all liabilities. The 7th, 8th, and 9th days of August have been fixed upon as the most eligible time for holding the Show, avoiding alike the Goodwood races, at which the Duke of Richmond and the Earl of Eglinton must be present, and the commencement of the shooting season. Part of the public Green of Glasgow has been kindly granted by the magistrates as the site for holding the Show, which is peculiarly adapted for the purpose, and will afford abundant accommodation. It has been resolved, instead of building a temporary erection, to have the public dinner within the City Hall of Glasgow, which can, at comparatively small expense, be fitted up to accommodate 1800 people with comfort. A plan of the Green, and the portion allotted for the Show, at the Flesher's Haugh, was exhibited. It seemed to satisfy all present, and it was left to a committee that were appointed to make every proper arrangement for securing the grounds, and for the necessary accommodation of the committees, the judges, and all concerned in the proceedings. The following are the plans for the three days of the Show —Wednesday, 7th Aug —The exhibition of agricultural implements, dairy produce, roots, seeds, and plants, to conclude with the Committee's dinner, and a grand ball in the evening Thursday, 8th Aug, will be the great day—set apart as it is for the general show of cattle, horses, sheep, swine, and the whole of the articles exhibited on Wednesday The business will be wound up by a grand public dinner in the City Hall, with the Duke of Richmond, president of the Society, in the chair Friday, 9th Aug —This day will be employed in the exhibition of the prize stock, implements, &c It was also arranged that Mr Smith, of Deanston, and Professor Johnston, should, either at the public breakfast, or at some other time during the proceedings, deliver lectures on draining and agricultural chemistry It was stated that the City Hall would accommodate 1800 at dinner, and it was agreed that tickets should be on sale, *to members only*, until the 27th July —thereafter the public to be served as they applied; a certain portion, until a particular date, being laid aside for the gentlemen belonging to Societies in England and Ireland.

FARMERS' CLUBS

Chelmsford Wool Fair —Mr. Towers, who presided [illegible] as Shakspeare [illegible] this occasion, made the following [illegible] at the public dinner on [illegible] remarks on the state of the wool trade He stated that the buyers had said there had been a material rise in wool over last year, though not in proportion to what was stated, but still a material rise, and they would see that it was impossible it should not be so when he detailed the fact that in 1843, advancing from several former years, the export of wool to Belgium and France was 8,000,000 lbs —6,802,000 lbs to the former, and 1 077,000 lbs. to the latter—as was shown by the return on the wool-trade made on the motion of Mr Miles. Now, in fact, this had been going on at the same time with a decrease in the import of wool If they looked back to the same document, they would find that from 1836 to 1840, the average import of foreign wool was 51,406,049 lbs, but from 1841 to 1843 the average import was only 50,410,902 lbs Therefore, there had been in the last three years a diminution of about 4,000,000 lbs. in the import of wool, which had taken place at a period when, from the extension of mechanical skill in the production of machinery, the competing power of the manufacturers had been largely increased; and, strange to tell, the sales of perfect and completed manufactured goods during that time, had only maintained the average of little more than five or six millions How was this to be accounted for? By this extraordinary fact, that there had been of late not only an export of 8,000,000 lbs. of their wool against an import of 50 millions some odd thousands, but an export of British woollen and worsted yarn to the amount of 7,906 392 lbs, being an increase on the former year of 1,423,262 lbs There had, therefore, been a double export of the raw material, first of our wool, and then of woollen and worsted yarn, which was the first manufacture from the wool; and this had fallen so heavily upon the reduced imports, that the manufacturers of the country were found to be in want of wool to meet the magnitude of their operations. He should be unwilling to check the desire of the sellers to sell, yet as the proceedings of this meeting were going forth to the country, and giving a tone to other fairs, it would have been wrong in him not to have stated relatively the situation of the buyers and sellers. There were points in the current year most favourable to the sellers, the buyers were consulting their interests in buying their wools on the most favourable terms they would offer them; and he did not believe that by holding back and speculating on the price, the growers would be consulting their own interest, for he did not think the farmer had a right to be a speculator But let the buyers be aware of this, that he had placed it beyond contradiction that it was their interest to make purchases provided they received offers favourable to their views. Let him call attention to the fact, that in Belgium and France the manufacturers admitted that British wool was of the greatest importance to them, as they required it to form the warp for their finer wools, in making the cloths and

the previous quality of goods in which they all have Yorkshire trade.—*From the Chelmsford Chronicle.*

West Norfolk.—At the late meeting of this Agricultural Association Mr. Hamond made the following remarks:—If you go into the society of intellectual farmers you will hear them talk of their business, of how they can produce the best crops by the most economical means; how one crop answers, how another answers, what are the best kinds of manure, and how to apply chemistry to farming. All these things tend to open men's minds, and to make them better farmers and better men. And if any of us knows a little bit of chemistry, let us not bottle it up nor take out a patent for it. There has been a great deal written by Professor Henslow on the subject of gypsum. I tried a little, but did not get on at all with it. Instead of using the sulphate of lime, I mixed sulphuric acid with water, and watered the manure-heaps with it. I do not profess to have made an accurate experiment; but after using twenty loads of this manure, I can say there was a great improvement in the tops and bottoms of Mangold Wurzel. I have turned over every load of manure with diluted sulphuric acid. If you like to try it, one gallon of sulphuric acid, which costs 1*s.* 9*d.*, to 36 gallons of water, will be the quantity for 20 loads of manure. The experiment is not very expensive, and I really would strongly recommend you to try it.

Reviews.

Supplement to Loudon's Encyclopedia of Agriculture. By J. C. Loudon, F.L.G.Z., and H.S., &c. Longman, Brown, Green, and Longmans. 1844.

Those who possess the "Encyclopedia of Agriculture," published by the late Mr. Loudon in 1825, will need this volume to complete that work. It brings down improvements in the art of field culture from 1831 to 1843 inclusive.

These improvements are enumerated in an instructive Preface, from which we extract the following paragraphs:

"The functions of the leaves of plants are beginning to be more generally understood; and hence, also, the importance of allowing sufficient space for their exposure to the sun and air, by wider sowing or planting, by judicious thinning, and by pruning.

"Hence, also, when plants are to be destroyed, this may be effectually done by cutting off their incipient leaves as fast as they appear. In this way Ferns and other perennial weeds in pastures may be more easily destroyed than by any other mode; and the same may be said of weeds growing up from the bottoms of ponds.

"As a proof that the use of leaves was not understood by practical men, and even by the officers of the Highland and Agricultural Society of Scotland, so lately as 1836, we may refer to the Transactions of that body; in which we find the Society giving a premium for an essay on the destruction of Ferns in pastures, to a candidate who recommends as the best mode the irrigation of these pastures. The irrigation of pastures on which Ferns abound may be considered impracticable in ninety-nine cases out of a hundred.

"Growth and maturation in plants are two separate processes, and when either is the main object of culture, the other should be prevented or checked; thus when seeds or fruits are maturing, the elongation of shoots and the production of leaves should be checked, by pinching them off as fast as they appear. Hence the use of topping Beans, Tobacco, Woad, and even Potatoes; not to mention Vines, Gooseberries, Raspberries, Peaches, and other garden fruit shrubs and trees.

"By preventing the formation of seeds or fruits, more strength is thrown into the plant generally; and if it is a plant which produces bulbs, tubers, or underground stems, as substitutes for seeds, these will be increased in size. Hence the use of picking off the blossoms of Potatoes.

"Plants imbibe nourishment from the soil, chiefly from the points of the fibres at the extremities of their roots. Hence, the practice of banking up hedges, Beans, Potatoes, and other plants in drills, and of watering, stirring the soil, and laying manure close to the stems of trees and plants, is erroneous in principle and often injurious in effect, by cutting off the fibrils, or, in the case of Potatoes, the underground shoots on which the Potatoes are formed. In some cases, however, cutting off the extremities of the roots is useful by increasing the number of fibrils, and consequently of the spongioles or mouths by which nourishment is imbibed.

"Hence the Berwickshire practice of tabling hedges, so much recommended and so generally followed by Scotch bailiffs, foresters, and hedgers, is for the most part a waste of labour; unless, indeed, the object be to stunt the growth of the hedge, and prevent its roots from robbing the soil of the adjoining fields. The practice of earthing up Turnips was once in vogue, but it is now ascertained to be a certain mode of instantly checking the swelling of the Turnip, by the pressure of the soil which is thrown up to it by the plough.

"The progress of the ripening of seeds and fruits in general goes on in a geometrical ratio, and hence the great nicety required to determine the moment when seeds or fruits should be gathered, which period varies according to the purpose to which the seeds or fruits are to be applied. The last change which takes place in the ripening of Wheat is an increase of bran or husk, and a relative diminution of farinaceous matter or flour; and hence the immense difference in the produce in flour, between that of the grain of a field of Wheat cut down at the proper time, and a field of Wheat allowed to be over ripe. Too much importance can hardly be attached to this subject.

"Draining water is found to supply oxygen, potash, carbonic acid gas, and ammonia, all which serving as manures for plants, it follows that irrigation, even in cold climates, is beneficial to Grass lands, altogether independently of supplying water as an element of growth, which in cold climates is seldom wanted in that capacity.

"More importance is now being attached to the ascertaining of the mineral constituents of plants, such as alkalies and alkaline earths, phosphorus, sulphuric acid, silica, &c., than was the case before the appearance of 'Liebig's Organic Chemistry.'

"The permanent fertility of a soil is found to depend more on the inorganic substances which it contains, (for example, on the proportion of alkalies and alkaline earths which it holds in combination with the silicic, phosphoric, sulphuric, and other acids,) than on its organic constituents, such as humus or decaying vegetable matter; for all organic matter in soil, whether that soil be naturally good or bad, is sooner or later exhausted by the growth of plants; and if the supply is not kept up, the soil reverts to its original state, except in so far as it may have been improved mechanically by draining, levelling, shelter, &c.

"Alkalies are the most important inorganic constituents of soils, and when a soil has been exhausted of them by cropping, no manure that does not contain alkalies will restore their fertility for agricultural plants.

"The poorest soils are almost invariably those which contain least alkalies and alkaline earths.

"Animal manures contain a much greater proportion of the inorganic constituents of plants, than vegetable manures; and the most powerful of animal manures are those of carnivorous or omnivorous animals; for example, of the human species.

"Saline manures not only supply food, but, acting as stimulants, enable plants to derive more food from the soil and the atmosphere than they otherwise would do.

"The ammonia of liquid or other manures may be fixed by gypsum or sulphuric acid; or, in default of these, it may be prevented from evaporating by mixing with soil or diluting with water. In general the most convenient and economic mode for the British agriculturist is to mix it with farm-yard manure, or, what is better in our opinion, plenty of surface soil.

"The chief practical advantages which have as yet resulted from the recent discoveries in chemistry, as applied to agriculture, are the employment of saline manures, and the recognition of their importance, the mixing of azotised (nitrogenised) with unazotised (unnitrogenised) food in feeding and fattening cattle, and the procuring greater warmth for the domestic animals of the farm.

"The most useful practices which have obtained extended diffusion within the last ten years are, the frequent drain system, long practised in Essex and Suffolk, but recently brought conspicuously into notice by Mr. Smith of Deanston; the use of draining-tiles instead of stones; the use of the subsoil plough, and of the cultivator as a substitute for the plough in various cases; the greater eagerness to procure improved implements, machines, and buildings generally; the mixture of soils; the greater value set on urine and liquid manure generally; the use of single-horse carts; the selection of improved varieties both of animals and plants, and the employment of land agents, conversant with agriculture, instead of lawyers or others who have little or no agricultural knowledge.

"The details which have led to the above summary will be found in Liebig's 'Organic Chemistry,' and 'Animal Chemistry;' Johnston's 'Agricultural Chemistry;' Trimmer's 'Practical Chemistry for Farmers and Landowners;' Solly's 'Rural Chemistry;' Dr. Playfair's Lectures on Rearing and Feeding Cattle, published in the 'Journal of the Royal Agricultural Society,' vol. iv.; Donaldson's 'Manures, Agricultural Grasses, and General Management of Landed Property, &c.' The greater part of this Supplement consists of extracts from these works; and from the 'Quarterly Journal of Agriculture,' the 'British Farmer's Magazine,' the *Gardeners' Chronicle*, and the 'Gardeners' Magazine.'"

The information given in this volume is arranged and classified with all that skill and order for which its author was distinguished. In Part 1st Agriculture is considered as to its origin, progress, and present state. In Part 2d it is considered, subjectively, as a science and an art; thus we have, under successive heads, an immense mass of matter on the animal kingdom, the mineral kingdom, and the atmosphere, with reference to Agriculture; on the mechanical agents employed in Agriculture; and on the operations of Agriculture. In Part 3d Agriculture as practised in Britain is described, more especially with reference to the arrangement and improvement of estates. And Part 4th gives information on the statistics of British Agriculture. Though certainly a supplementary work, it is nevertheless to a great extent complete, inasmuch as the practice, and our knowledge of the science of Agriculture have improved to an unprecedented extent within the period the improvements of which it professes to detail. We therefore recommend this work even to those who may not be in possession of the original edition. It contains a great mass of useful information on agricultural subjects, admirably arranged, and fully illustrated by wood-cuts, where these are necessary.

Farming for Ladies; or, a Guide to the Poultry-yard, the Dairy, and the Piggery. By the Author of "British Husbandry." London: John Murray, Albemarle-st.

This is an elegant octavo volume, containing in full detail information on the management of all kinds of Poultry, with chapters on the Pigeon, the Rabbit, the Goat—on the Dairy and the Piggery. It is illustrated by woodcuts whenever these are required; and it is ornamented by a drawing of the Queen's poultry-yard at Windsor. The Preface says that it is not intended for the mere cottager, nor for persons of large fortunes, but for those ladies in the middle ranks of life who study healthful domestic economy, either for the pleasure or the profit which it affords; and it certainly is just the kind of book which any one not possessed of practical experience on the subject would wish for, to receive instruction from. The chapters on the Dairy contain a variety of information, by attention to which, professional as well as amateur farmers might benefit.

Miscellaneous.

Adulteration of Manures.—A paragraph somewhat as follows would seasonably issue from your Journal:—"It is projected by several leading agriculturists to establish, during the Southampton Meeting, a Protection Society against the frauds practised upon the farmer by the importers and manufacturers of manures, Linseed-cake, &c. &c. It is well known that the whole of the 'scutch' (the refuse from the carriers' yards) from Scotland, is imported into Hull to be mixed with the crushed bones, and sold to the simple farmers as genuine bone-dust. Also that foreign Linseed-cake of very inferior value is re-crushed with the dregs of the Linseed-oil, and sold by the Hull manufacturers as English cake. It is lamentable to observe merchants moving in a respectable station of society demean themselves by such gross swindling. It is intended by the Society to employ chemists to analyse samples of manure and cake, and to make examples of dishonest traders, by instituting actions-at-law at the cost of the Society. It is earnestly hoped the farmers generally will associate themselves with the Society, that an immediate stop may be made to the robbery imposed upon them."—*Agricola, in the Farmers' Journal.*

Scientific Lecturers.—To the Council of the Royal Agricultural Society of England: The Memorial of the Cardiff Farmers' Club, respectfully sheweth,—That your Memorialists feel deeply impressed with the great advantages which must result to the Agriculture of this kingdom from the extended operations of the Royal Agricultural Society. That they further believe that in the formation of farmers' clubs your Council will possess an additional and most important means of diffusing practical and useful knowledge amongst the cultivators of the soil. That your memorialists beg leave most respectfully to state that they are fully of opinion that the great objects contemplated by the Royal Agricultural Society would be greatly and most beneficially promoted by the employment of real practical and scientific lecturers, who would from time to time visit the various farmers' clubs now formed, as well as to assist in the formation of others, and to convey through the means of lectures or otherwise to these clubs the various improvements in the cultivation of the land; in the breeding and feeding of stock, and in the most approved varieties of grain, roots, &c., which have been successfully adopted in other parts of the kingdom. That the recent establishment of so many farmers' clubs in different parts of England and Wales offer facilities for diffusing such information throughout the rural districts which have never before occurred; your memorialists therefore earnestly hope that the Royal Agricultural Society of England will adopt such measures as may seem to them best adapted to the attainment of so desirable an object. Signed on behalf of the club, E. David, Chairman.—*Report of the Cardiff Farmers' Club.*

The Tick, Fly, &c.—Sheep are much exposed to the attack, and suffer much from the effects, of various insects and vermin. One of the most common and well-known is the tick, which though commonly about the size of a pea, is sometimes much larger. It attaches itself to the skin by means of sharp claws at the extremity of the legs, and pierces the skin with sharp instruments attached to the head. The tick propagates rapidly, and is often found in great numbers on a single sheep, selecting the neck and shoulders in preference to other parts. It may be destroyed by the application of turpentine, linseed oil, or mercurial ointment, or dipping in a solution of arsenic. Lice are sometimes a source of much annoyance, but may be destroyed by mercurial ointment, solution of arsenic, or tobacco-water. The fly is a still more formidable enemy, causing more irritation, and leaving behind more severe effects. It abounds mostly in woody localities, and in the month of May deposits its eggs on the sheep, selecting a sore, if there is any to be found, which is often the case, particularly about the head. The maggots being hatched burrow under the skin, causing severe irritation, and producing frequently extensive and troublesome wounds. The sheep exhibit much uneasiness soon after being struck, often stamping, biting themselves, and running about the field with much violence. The wounds, if neglected, soon spread, and I have known the most severe and complicated fistulous wounds produced thereby,—extending between the shoulders and becoming incurable. The most simple preventive to the attack of the fly is the application of coarse whale oil to the parts most likely to be attacked. The fly has such dislike to even the strong smell of the oil, that it acts as a safe protection, and is much more simple than the application of a plaster, as sometimes practised. A striking instance of the effect of the oil is mentioned by Mr. Hogg in his "Shepherd's Guide." As a local application, immediately after the sheep have been struck by the fly, white lead is one of the best, and it will also act as a preventive.

It is rendered still more efficient when mixed, as in the following recipe, and on being scattered over the parts will speedily destroy the maggots:—

White lead	. . . . .	4 ounces.
White arsenic	. . . . .	1 „
Sulphur	. . . . .	6 „
Cinnabar of antimony	. . .	2 „

Each to be finely powdered, and the whole then well mixed. It may be rendered weaker, and perhaps more suitable when employed as a preventive, by diminishing considerably the proportion of arsenic. The following is the application used at Holkham successfully in the flocks of the Earl of Leicester:—

White arsenic	. .	1¼ ounce to 1 gallon of water.
Soap	. . .	2 „ „
Tobacco	. . .	2 „ „

The arsenic is boiled in a bag, and kept stirred at the time of boiling. The tobacco is also boiled in the same manner, and put into the water when cold. The soap is cut in thin slices, and the whole of the mixture boiled for half an hour. One pint and a half to be applied to each sheep. Earl Spencer observes—"It is better to dip the lambs immediately after the ewes are shorn than after weaning. The shearing the ewes destroys or removes the ticks which were upon them, and the dipping destroys those which were upon the lambs; whereas, if it is postponed till the lambs are weaned, the wool on the ewes will have then grown long enough to shelter ticks, which have come upon them from the lambs after the time of shearing." If the sore, from inattention or neglect, has spread, the application of the following astringent powder will be desirable:—

Prepared chalk	. . . .	6 ounces.
Alum	. . . . .	1 „
Armenian bole	. . . .	1 „
White lead	. . . .	1 „
Chloride of lime	. . .	1 drachm.

Each to be finely powdered, and the whole then well mixed together.—*From Mr. Spooner's Work "On the Sheep."*

Cultivation of Root-crops on Heavy Land.—I must first observe that much of my land has been laid out in wide ridges of eight yards, gathered twice from the flat, and drained where needful with tiles and stones up every furrow; the remaining part of the farm is in lands of six feet or two yards wide, and has been drained many years since with shallow stone drains in a direction across the run of the furrows at intervals of eight or nine yards, and with tile heads. This method of draining does not answer upon our close and adhesive clay soils, as it does not carry off the surface water readily. It is my intention to set out these lands afresh, and to put them (as I have done the others) into ridges of eight yards in width, and to intersect the old drains, where necessary, by running others up the *new* furrows, at intervals of sixteen or thirty-two yards. By this means I hope to give the old drains a quicker vent, and to enable them to discharge the water *more* readily than they do at present. Other drains may at a future period be laid in those furrows which are at first missed, whenever it may appear necessary. We will now suppose the ground drained, and rendered as sound and dry as such land can be made. We will also suppose the land to be in fair condition and tolerably free from couch and root weeds (for should the field have been run out, as we say, and full of couch, a naked fallow on this kind of soil must of course be resorted to). My mode of proceeding will be thus:—I shall in the first place have the ground very carefully looked over, and with three-grained forks dig up every blade of couch and every dock that can be seen; having previously finished, as I said on a former occasion, sowing my winter Vetches and drilled my Wheat. The land intended for a root crop is then to be ploughed, in a direction diagonally to the run of the furrows, into single bouts of twenty-seven or twenty-eight inches; or into two-bout ridges where Cabbages are intended to be grown. The appearance of the field will then be like garden ground laid up in trenches. I should plough as deep a furrow as practicable, exposing a large surface for the winter frosts to mellow and sweeten. After the land has become sufficiently pulverised and the trenches are in a dry state, with a double mould-board plough I purpose thoroughly to open out and considerably deepen them, directly following with a stout plough, having the turn-furrow taken off, and with a strong team of horses harnessed at length, subsoil or stir the hitherto unmoved soil in the bottom of every furrow trench, as deeply as may be practicable—six or eight inches at the least. This being not trampled on while in a moist and tender state, will lie light and hollow for the air and frost to sweeten and pulverise. Nothing will have to be done now to the land till the dry weather sets in in the early spring, be it in February or the beginning of March; at which time I intend to set the dung carts to work, and having spread the manure carefully in the bottom of the trenches, with a pair of horses driven abreast cover it up, by splitting or reversing the bout ridges. These are again to remain untouched till well dried and pulverised, when an opportunity will be afforded of subsoiling or stirring the intervals. Thus, then, nearly the whole of the ground will have been loosened to the depth of twelve inches at the least, and a sufficient tilth gained, and that too at no very ruinous expense. I prefer to cultivate my Turnips and other roots (such as Cabbage and Beet) on the ridge system after the Scotch manner, because it will give me an opportunity of working the ground deeply and frequently, during the growth of the crop; and because it will allow me, at the time of singling out the Turnips, to draw the earth well away from the plants, whereby they appear to swell, and form better bulbs.—*Mr. N., in the Report of the Gloucester Farmers' Club.*

Serious Loss of Sheep.—Some time ago, the extraordinary number of 49 sheep had been lost by Mr. Fountain, of Leake, under the following circumstances:—The flock had been for some weeks kept on Swede Turnips, and on being removed, was driven for a few miles, and placed on a piece of meadow land. The next morning, many of the sheep were perceived to be afflicted with symptoms of lethargy, and appeared to be otherwise out of condition; and within forty-eight hours of their being placed on the meadow land it was found necessary to slaughter from fifteen to twenty; since then they have continued dying, and on Friday night the number lost amounted, as above stated, to forty-nine. The animals, it seems, were afflicted with inflammation of the kidneys, supposed to have been produced by the distance they were driven, and the sudden change of keep.—*Boston Herald.*

Notices to Correspondents.

BOOKS.—*S.*—Low's "Elements of Practical Agriculture."

BOKHARA CLOVER.—*F. E.*—This plant—such specimens of it as we have seen—is only edible by cattle when it is young; when old it is shrubby. Its name is derived from that of the country from which it is said to have been brought.

CLOVER SEEDS.—*Carl.*—We are in the habit of sowing 10 lbs. of Red Clover, 5 lbs. of White Dutch, and 5 lbs. of Trefoil per acre. Our Clovers are all fed off by sheep, and therefore we sow no Rye-Grass, for much of it would be left on the ground uneaten, and the pasture would be left in a tangled condition. A smaller quantity per acre, preserving the proportion of the different kinds, would probably be sufficient seed per acre. We should prefer your No. 1 mixture to the other, *i. e.*, 14 lbs. Red Clover, 3 lbs. White Clover, 2 lbs. Trefoil, 2 lbs. Rib-Grass, half peck of Rye-Grass per acre to 12 lbs. of White Clover, 2 lbs. of Trefoil, and half a peck of Rye-Grass. What may be best for the southern part of the kingdom might not, however, suit the North Riding of Yorkshire.

DAIRY STOCK.—*X. Z.*—A cow will generally consume about 2 cwt. of hay a week, or about 130 lbs. if, as you propose, you give her ¾ cwt. of roots per diem besides. You can supply with roots from October till May or June; and if your land will yield an average crop of 30 cwt. of hay per acre, half of it mown will supply you with more hay than you will be able to consume in this way with the stock which the other half will keep during the summer months, so that you will have to supply them with Clover, Vetches, &c., from other land during the summer too. The data now supplied will enable you to calculate for yourself.

FALLOW LAND.—*R. W.*—You had better ridge-drill the land up at intervals of 26 inches, and sow a late Turnip as soon as you have rain; or if your land is thoroughly dry and pulverised, you may sow it now—4 or 5 lbs. of seed per acre—and wait for rain. The failure of the Potato set is a very common complaint this year.

LIME.—*Cato.*—If stone-lime be burnt and left in the heap exposed to wet and winds, &c. (it not being wanted for use before next spring), its power of action on the land will be injured, but not destroyed.

LIQUID MANURE.—*Constant Reader.*—It is not right to put caustic lime amongst urine; it will volatilise the ammonia. Mr. Dimsdale has been applied to.

LUCERNE.—*J. Heaton.*—Your Chinese Lucerne is darker in the flower, and is also a more luxuriant specimen than any we have seen this year, but it does not otherwise appear to differ from the common variety. The dry weather we have had has made it fortunate that you did not wait till after the first mowing for your seed-crop.

MANURE, &c.—*Cottage Gardener.*—Your fault must have been one of omission, not of commission, *i. e.*, if the failure of your Onions is chargeable on you, and not on the weather; the manure you applied cannot have killed them.

SUPER-PHOSPHATE OF LIME.—*Subscriber.*—It differs from the phosphate in containing twice the quantity of phosphorus, and in being soluble in water. Apply 2 cwt. per acre, mixed with turf-ashes early in spring upon your Grass-land.

TITHE AND RENT.—*G.*—Theoretically, tithe is one-tenth of the produce. Rent may be one-half, one fourth, one-sixth of the produce, or any other fraction, dependent upon the expenses and returns of cultivation, and the demand, whether natural or artificial, which may exist for land. You will thus see there is no necessary proportion existing between rent and tithe.

WEED.—*R. H. C.*—Your weed can be extirpated only by perseverance in cutting the plant off whenever it appears. We know of no easy plan of destroying it.

***As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, July 1.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	10	to 4s	2	Best Downs & Half-breds	3s	10	to 4s	0
Best Short Horns	3	6		3	10	Best Long-wools	3	8		3	10
Second quality Beasts	3	2		3	6	Ewes and second quality	3	4		3	8
Calves	3	4		4	0	Lambs	4	0		4	6
Pigs	3	4		4	0						

Beasts, 2819; Sheep and Lambs, 23,470; Calves, 197; Pigs, 369.

We have a very fair supply of Beasts to-day, both as regards numbers and quality; buyers are also numerous, and the dead trade of late having been pretty good for Beef, there was a brisk demand for the best qualities at an advance of nearly 2d per 8 lbs on last Monday's prices; although 4s 2d was obtained for several of the best Scots, and 3s 10d for several of the best Short-horns, yet many very good of both descriptions were sold at 2d per 8 lbs less. In Sheep and Lambs there is an increase of numbers, on the whole, the supply of the best qualities of Sheep, however, is but moderate; they fully maintain, and in some instances rather exceed, our late quotations, some of the most selling Downs, &c. making 4s 2d, and Longwools 4s per 8 lbs, still, the trade ruled very heavy, and these prices could not be currently obtained. There were a great many Lambs, and the trade for them very heavy at rather lower rates. Calves are heavy trade, at rather lower prices. Pork remains about the same, but a dull trade.

FRIDAY, July 5.

We have quite enough Beasts to meet the demand, though rather fewer than last Friday; prices are rather lower; the best Scots, &c., make no more than 4s, and the best Short-horns 3s 8d. The supply of Mutton is good, and prices remain the same as on Monday. We have a large quantity of Lambs, the trade for which is very bad, owing to immense quantities being sent down during the week; some of the very best make 4s 6d per 8 lbs, but many good ones are sold at from 4s to 4s 4d. Calf-trade is a little brisker, but no higher prices are obtained. Pork about the same.

Beasts, 748; Sheep and Lambs, 19,180; Calves, 360; Pigs, 300.

41, West Smithfield.

WOOL.—BRITISH, FRIDAY, July 5.

We are able to report to-day as favourably of our English Wool Market as we did last week. At the several Wool Fairs which have recently been held, the greater part offered has been sold, but not at an advance upon our late quotations. We see nothing in the prospects of the trade which leads us to look for any material and permanent advance in price.

JAMES PEARCE, Wool Broker.

POTATOES.—SOUTHWARK WATERSIDE, July 1.

The weather has been all that could be desired since our last; there was a fine rain fell in London and its suburbs on Tuesday last, which, without inundation, continued for eighteen hours, and being followed by some cloudy days, must prove very beneficial to the crops. There was but little done in this Market during the past week. Perth Reds have finished badly, several damaged lots have been sold for the cattle at 30s.

CORN EXCHANGE, MONDAY, July 1.

Our supply of English Wheat by land carriage coastwise this morning was moderate, nevertheless the trade ruled exceedingly heavy, and a large proportion remained unsold, although offered at a decline of upon 1s. to 2s. per qr. The arrivals of Foreign are rather large; millers evinced great reluctance to purchase, and where sales have been effected, late prices were barely maintained. The Flour lately arrived from Canada appears to be of good quality, and is saleable in retail at 32s. to 34s. per barrel.—Barley was held at our quotations, which buyers were unwilling to comply with, and business was very limited.—Beans must be written from 1s. to 2s., and Grey Peas 1s. cheaper, but the value of White is supported.—Having a large show of Oats, sales were slow at a decline of 1s. to 2s. per qr.

FRIDAY, July 5.

The English Wheat left over from Monday has been pretty well cleared off at that day's prices; the demand for Free Foreign is exceedingly limited, but the trade, nevertheless very firm, a considerable quantity of rain having fallen during the week, with an appearance of more.—In Barley there is scarcely any business doing.—Beans and Peas are difficult to quit, and rather cheaper.—The Oat-trade continues very heavy, and must be written fully 6d. lower than our late quotations.

KINGSFORD AND LAY.

HOPS, FRIDAY, July 5.

The accounts from Sussex, Weald of Kent, and Worcester, continue to come unfavourable, and the market remains the same as last week.

FAREBROTHER & SONS, Hop-Factors.

COVENT GARDEN, JULY 6.—The supply of Fruit and Vegetables have, in most instances, been very good during the past week, but trade for some things has been dull. Pine Apples have not varied much since our last report. Grapes are also selling at nearly the same prices; among them we observed fine specimens of Black Hamburghs, which are very plentiful. Melons are good, and although not abundant, are sufficient for the demand. Peaches and Nectarines are quite as plentiful as they were last week, and are offered at the same prices. Cherries are likewise good and plentiful. Strawberries are abundantly supplied, and are low in price; among them are good samples of Myatt's British Queen and Keen's Seedling, as well as of other varieties. Ripe Gooseberries are plentiful, as are also Currants: the latter are very good in quality. Of Vegetables, except in one or two instances, there is an abundance. Peas, in particular, are very plentiful; but the demand for them is not good, and, consequently, they are low in price. The best French Beans are offered at about 10s. per half-sieve. A considerable quantity of new Potatoes, of good quality, imported from Holland, has been in the market this week. Asparagus is becoming scarce; a small quantity may, however, still be procured; the best is selling at 4s. 6d. per 100. Rhubarb is not plentiful, being nearly over for a season. There has been little alteration in the prices of Cauliflowers, Cabbages, Carrots, and Turnips since last week. Vegetable Marrow is offered at from 1s. to 2s. per dozen. Leeks are very small. Lettuces and other Salading are abundant. Among Cut Flowers we noticed Erica ampullacea and cerinthoides, Heliotropium peruvianum, Lilium longiflorum, Sweet Peas, Pinks, Lily of the Valley, Verbenas, Pelargoniums, Gardenias, Fuchsias, Cacti, Moss, Provence, and China Roses.

FRUITS.

Pine Apple, per lb., 4s to 8s	Oranges, per dozen, 1s to 2s 6d
Hothouse Grapes, per lb., 3s to 6s	— per 100, 6s to 15s
Melons, each, 2s to 6s	Lemons, per dozen, 1s to 2s
Peaches, per dozen, 6s to 12s	— per 100, 6s to 14s

Supply large, with a dull trade at the above prices.

HORTICULTURAL SOCIETY OF LONDON.—LIST OF PRIZES

offered at Nine Exhibitions in the Garden, in 1854, viz.:

MEDALS AND REWARDS.

The Society distributes the following Medals and Rewards; viz.:

	Value—£	s.	d.
C. The Certificate		6	12	6
SB. Silver Banksian Medal		1	0	0
SK. Silver Knightian Do.		1	5	0
LS. Large Silver Do.		3	15	0
SG. Large Silver-Gilt Do.		4	0	0
GB. Gold Banksian Do.		7	0	0
GK. Gold Knightian Do.		10	0	0
LG. Large Gold Do.		20	0	0

Exhibitors to whom any of these shall be awarded can exchange them one for another, or may receive their value in money, or in plate. In case an Exhibitor shall receive a First Prize in any one Letter, he shall not be entitled to receive any other Medal in the same Letter, except in *CC*, *DD*, and *EE*.

CLASS I.—FLOWERS; for which Nurserymen and Private Growers exhibit independently of each other.

A. Pelargoniums, in collections of 12 new and first-rate varieties, cultivated with superior skill, in pots of 24 to a cast. GB—SG—LS—SK.

B. Pelargoniums, in collections of 12 varieties, in pots of 12 to a cast. SG—LS—SK.

N.B. Persons exhibiting in *B* cannot also exhibit in *C*.

C. Pelargoniums, in collections of 6 varieties, in pots of 8 to a cast. LS—SB.

D. Rhododendrons, in pots; not fewer than 6 plants, in 6 varieties. LS—SK—SB.

E. Roses, in pots; Amateurs to show in collections of 12, Nurserymen in collections of 24, distinct varieties. GB—SG—LS.

N.B. It is the wish of the Society in a future season, to require Roses to be shown exclusively in pots; and not to allow cut specimens to be exhibited at all.

F. Moss Roses in loose bunches, so as to exhibit, as far as possible, the habit of the variety; in 12 varieties. SK—SB—C.

G. Other Roses, exhibited as in the last letter, and in 50 varieties. LS—SK—B—C.

N.B. No one who exhibits in this letter can also compete for the following.

H. Other Roses, exhibited as in the letter *F*, and in 25 varieties. SK—SB—C.

N.B. Higher medals than those here offered for Roses cannot be given by the Judges. And if Roses are brought for exhibition without attention to the regulations here explained, they will not be allowed to be placed on the tables.

I. Cape Heaths, in collections of 20 distinct varieties. GB—SG—LS.

N.B. It is expected that the same plant shall not be exhibited on more than one occasion.

K. Cape Heaths, in collections of 6 distinct varieties. SG—LS—SK.

N.B. No person who shows in *I* will be allowed to exhibit also in *K*.

L. Calceolarias, in sixes; in pots of 12 to the cast. LS—SK—SB.

M. Carnations, in pans of 24 distinct varieties. LS—SK—SB.

N. Picotees, in pans of 24 distinct varieties. LS—SK—SB.

O. Pinks, in pans of 24 distinct varieties. SK—SB.

CLASS II.—FLOWERS; for which all persons are admitted to equal competition.

P. Stove or Greenhouse Plants, in collections of 30 plants. GK—GB—SG—LS.

N.B. Heaths, Calceolarias, Fuchsias, Greenhouse Azaleas, Rhododendrons, Orchidaceæ, Cacti, and Pelargoniums, to be excluded from *P*, *Q*, and *R*.

Q. Stove or Greenhouse plants, in collections of 15 plants. GB—SG—LS.

N.B. Persons exhibiting in *P* not to compete in *Q* also.

R. Stove or Greenhouse plants, in collections of 6 distinct species. SG—LS—SK.

N.B. Persons exhibiting in *P* or *Q* will not be allowed to compete in *R* also.

S. Greenhouse Azaleas, in 12 distinct varieties. GB—SG—LS.

T. Greenhouse Azaleas, in 6 distinct varieties. SG—LS.

N.B. No one can show in both classes of Azaleas.

U. Stove or Greenhouse climbers, in collections of 6 species. SG—SK.

V. Exotic Orchidaceæ, in collections of not fewer than 20 species. LG—GK—GB

N.B. Exhibitors cannot show in more than one of the classes, *V*, *W*, and *X*.

W. Exotic Orchidaceæ, in collections of not fewer than 6 species. —GK—GB—SG.

X. Exotic Orchidaceæ in single specimens. SG—LS—SK.

Y. Plants in glass cases, grown on Mr. Ward's plan. SG—LS—SK.

N.B. It is highly desirable that these cases be made with a movable door, so as to prevent the condensation of the water on the inner face of the glass during the time of exhibition.

Z. Distinct varieties of Tall Cacti in flower. GB—SG—LS.

N.B. The GB and SG Medals are not to be given if fewer than six varieties are exhibited.

AA. Fuchsias in collections of 12 distinct varieties. LS—SK.

BB. Cinerarias, in pots, in collections of 12 distinct varieties SK—SB.

CC. Single specimens of new or extremely rare ornamental plants. SG—LS—SK—SB—C.

N.B. These Medals will be awarded by the Society's Officers, and not by the usual Judges. Exhibitors will particularly observe that none but new or rare plants can be exhibited under this letter. *Nothing will be regarded as new which has been exhibited in the Gardens in a previous season.*

DD. Miscellaneous subjects. SK—SB—C.

N.B. Cockscombs, Hemerocalles, Hydrangeas, and cut flowers, are altogether excluded from exhibition. Exhibitors under this head will not be thereby *entitled* to a pass ticket.

EE. Seedling Florists' flowers. SK—SB—C.

N.B. Every seedling must be shown singly, and must be marked with the name it is to bear. The same seedling cannot gain a prize more than once in the season. Pelargoniums are to be shown in pots, and not in a cut state. No person will be allowed to exhibit more than five seedlings at each meeting. Exhibitors under this head will not be thereby *entitled* to a pass ticket.

In Addition to any medals assigned to the classes *J*, *P*, *Q*, and *W*, the SK and SB medals are offered for the two collections in those classes which shall be best named by the Exhibitor.

N.B. The Society's officers, who will make this award, will be guided in their judgment by a consideration not only of the correctness of the names, but of the accuracy of the spelling, and the neatness of the writing.

CLASS III.—FRUIT, for which Market Gardeners, Fruiterers, or persons in the habit of regularly supplying the market, and private growers, exhibit independently of each other.

N.B. All Fruit must be FULLY RIPE and WELL-COLOURED; if the contrary it will be disqualified.

FF. Miscellaneous collections of Fruit, consisting of at least three different kinds. Peaches and Nectarines being considered as only one kind. GK—GB—LS.

N.B. Cucumbers, Tomatoes, Gourds, and similar Kitchen Garden produce, are excluded from this letter.

GG. Grapes. SG—LS—SK—SB.

HH. Nine apples. SG—LS—SK—SB.

II. Peaches or Nectarines, in dishes of six specimens SK—SB.

KK. Other kinds of Fruit. SK—SB—C.

Judges.—The Judges have the power of *increasing or diminishing* the number and value of the silver medals offered by the Society for particular objects, and also of *conferring* Silver Medals or Certificates in cases not contemplated in these regulations, if they think it necessary to do so.

The Judges are also required to bear in mind that the Society's Medals are offered less for new and curious objects, than for fine specimens of Horticultural skill, the design of the Council in instituting these meetings being not so much to encourage the collector as to reward the skilful Gardener; they are also not to make any award in cases where the objects exhibited do not appear worthy of a medal; or where a bad single exhibition might obtain a prize, merely because there is no better exhibition of the same class to oppose it.

Copies of the above list may be obtained at 21, Regent-street, upon application to the Secretary.

HAND-BOOKS FOR THE PEOPLE.

THE HAND-BOOK OF GARDENING; expressly intended for Persons possessing and fond of cultivating a Garden of moderate size. Price 2s. cloth, a New and Enlarged Edition.

THE HAND-BOOK OF BOTANY;
Or Linnæan Lessons on Common Plants, for Field and Garden Practice. Price 2s.

THE HAND-BOOK OF AGRICULTURE;
Chiefly for the use of those interested in the Allotment System. Price 1s. 3d.

THE HAND-BOOK OF COOKERY;
Intended for the use of the Middle Classes. Price 2s. cloth.

THE HAND-BOOK OF THE TOILETTE;
Having in view the union of Bodily Health with Beauty of Person. Price 2s. cloth.

Forming a Useful Manual in time of Need, when Professional Aid cannot readily be procured. Price 2s. cloth.

THE HAND-BOOK OF NATURAL PHILOSOPHY.
Price 1s. 6d.

In one small volume, price 15s.,

PAXTON'S POCKET BOTANICAL DICTIONARY.

In what may be called an age of Cyclopædias, when the compression of a great variety of information into one volume, in order to bring it within the means of persons of all ranks, is so universally sought, it is evidently desirable that the Gardener, and those connected with his profession, should be as well accommodated as other classes in this particular. No such work existing, however, prior to the issue of the present publication, its value will be at once apparent; since it combines the more essential features of a Botanical Catalogue, a Horticultural Guide, and a Technical Glossary.

Besides being of this comprehensive description, it is especially adapted for the Amateur and Floriculturist; who may, by carrying it in his pocket, examine all the plants that are at any time submitted to his inspection, and immediately derive every intelligence respecting the peculiarities or affinities of particular species which could reasonably be wished for. This is an advantage that can only be sufficiently estimated by those who have felt the want of such an assistant; and to all such individuals, as well as to every agent or friend of Horticulture, the Pocket Botanical Dictionary is decidedly indispensable.

Price 7s., Illustrated with Wood-cuts of Birds, Cages, &c.

NATURAL HISTORY OF CAGE BIRDS; their Management, Habits, Food, Diseases, Treatment, Breeding, and the Methods of Catching them. By J. M. Bechstein, M.D.

"It will be welcome to every gentleman's library or drawing-room table. It is superbly got up, with an immense number of vignettes, and, in fact rivals the beauty of the Annuals."—*Weekly Dispatch.*

"A very delightful book of its kind. . . . . It seems to us an indispensable book for the bird-fancier."—*Spectator.*

London: W. S. Orr and Co.; and W. R. Chambers, Edinburgh.

DARLEY'S SCIENTIFIC LIBRARY, for the Use of Schools, Private Students, Artists, and Mechanics.—It is the purpose of this Work to furnish a Series of Elementary Treatises on Mathematical Science, adapted to the wants of the Public at large. To youth of either sex at public and private schools, to persons whose education has been neglected, or whose attention has not been directed in early life to such studies, and to Artists and Mechanics, these little Works will be found particularly suited. The principles of the various Sciences are rendered as familiar and brought as near to our commonest ideas as possible: the demonstrations of propositions are made plain for the mind, and brief for the memory; and the Elements of each Science are reduced, not only to their simplest, but to their shortest form.

1. A SYSTEM OF POPULAR GEOMETRY. Containing in a few Lessons so much of the Elements of Euclid as is necessary and sufficient for a right understanding of every Art and Science in its leading Truths and general Principles. By George Darley, A.B. Fourth Edition, 4s. 6d. cloth.

2. COMPANION TO THE POPULAR GEOMETRY, in which the Elements of Abstract Science are familiarised, illustrated and rendered practically useful to the various purposes of Life, with numerous Cuts. (Second Edition.) 4s 6d. cloth.

3. A SYSTEM OF POPULAR ALGEBRA, with a Section on Proportions and Progressions. Third Edition. 4s. 6d. cloth.

4. A SYSTEM OF POPULAR TRIGONOMETRY, both Plane and Spherical, with Popular Treatises on Logarithms, and the application of Algebra to Geometry. Second Edition. 3s. 6d. cl.

"For students who only seek this limited knowledge of these sciences, there are perhaps no treatises which can be read with more advantage than Darley's Popular Geometry and Algebra."—*Library of Useful Knowledge. Article "Mechanics."*

Taylor and Walton, Booksellers and Publishers to University College, 28, Upper Gower-street.

ADAPTED FOR SCHOOLS, PRIVATE TEACHERS, AND STUDENTS.

COOLEY'S ELEMENTS of EUCLID, With Explanatory Appendix and Exercises. Price 4s. 6d. bound.

"The best edition of the Elements which has yet appeared."—*Athenæum.*

"Cannot be easily surpassed."—*Dublin University Magazine.*

COOLEY'S GEOMETRICAL PROPOSITIONS a Key to the Exercises appended to the Elements. Price 3s. 6d. bound.

COOLEY'S FIGURES OF EUCLID, with Enunciations. Price 1s 6d.

London: Whittaker and Co.: sold by all Booksellers.

One Volume, price 7s. 6d.

THE LIFE AND TIMES OF RIENZI.

Not less interesting than Sir E. Lytton Bulwer's eloquent romance, and scarcely less romantic, is this historical record of the Conspiracy of Gabrini."—*Monthly Repository.*

"To all who have read Sir E. Lytton Bulwer's 'Rienzi,' its perusal is, in a measure, a duty."—*Spectator.*

"A curious and pleasing volume, and full of matter of historical character and illustration."—*Literary Gazette.*

"The publication of this work is well-timed . . . . The Life of Rienzi is to us full of interest."—*Athenæum.*

"Those that wish to become acquainted with the true history of a man, who was, in some sort, the *Napoleon* of his own age and country, would do well to consult the extraordinary narrative of the 'Life and Times of Rienzi.'"—*Tait's Magazine.*

London: Whittaker and Co

PRINTED FOR

TAYLOR AND WALTON,

Booksellers and Publishers to University College,

UPPER GOWER-STREET.

DARLEY'S

SCIENTIFIC LIBRARY,

FOR THE USE OF

SCHOOLS, PRIVATE STUDENTS, ARTISTS, AND MECHANICS.

It is the *purpose of* this Work to furnish a Series of Elementary Treatises on Mathematical Science, adapted to the wants of the public at large. To youth of either sex at public and private schools; to persons whose education has been neglected, or whose attention has not been directed in early life to such studies; and to Artists and Mechanics these little works will be particularly suited. The principles of the various Sciences are rendered as familiar and brought as near to our commonest ideas as possible; the demonstrations of propositions are made plain for the mind and brief for the memory; and the Elements of each Science are reduced not only to their simplest but to their shortest form.

I.

A New Edition (being the fifth) *is now in the Press,*

A SYSTEM

OF

POPULAR GEOMETRY;

Containing in a few Lessons so much of the Elements of Euclid as is necessary and sufficient for a right understanding of every Art and Science in its leading truths and great principles.

By GEORGE DARLEY, A.B.

Price 4s. 6d., cloth.

II.

New Edition (just published),

COMPANION

TO THE

POPULAR GEOMETRY;

In which the Elements of Abstract Science are familiarised, illustrated, and rendered practically useful to the various purposes of life, with numerous Cuts.

By GEORGE DARLEY, A.B.

Price 4s. 6d., cloth.

III.

Third Edition,

A SYSTEM

OF

POPULAR ALGEBRA;

WITH

A Section on PROPORTIONS and PROGRESSIONS.

By GEORGE DARLEY, A.B.

Price 4s. 6d.

"For Students who only seek this limited knowledge of these sciences, there are, perhaps, no treatises which can be read with more advantage than Darley's Popular Geometry and Algebra."—*Library of Useful Knowledge, article "Mechanics."*

IV.

Second Edition,

A SYSTEM

OF

POPULAR TRIGONOMETRY,

Both Plane and Spherical.

With POPULAR TREATISES on LOGARITHMS, and the Application of Algebra to Geometry.

By GEORGE DARLEY, A.B.

Price 3s. 6d., cloth.

V.

FAMILIAR ASTRONOMY.

By GEORGE DARLEY, A.B.

With Engravings.—18mo, 3s., cloth lettered.

"There is a vast deal of astronomical information conveyed in a most winning and unassuming manner in this delightful little volume, which, not less for the novelty of its plan than the extent of its intelligence, reflects infinite credit on the taste and talents of its projector and editor, Mr. Darley."—*Sun.*

SILVER TEA-SERVICES.—A. B. SAVORY and SONS, Manufacturing Silversmiths, 14, Cornhill, London, opposite the Bank of England, submit the price of the following Silver Tea and Coffee Services. The Cottage Pattern is plain, standing on shell feet, thereon and either pot with a flower ornament on the lids. The King's Pattern is richly embossed with flowers and scrolls. The shape of either is new and elegant.

Cottage Pattern.		King's Pattern.	
Strong Silver Tea-pot	£12 12s.	Strong Silver Tea-pot	£12 6s.
Ditto Sugar-basin	3 15	Ditto Sugar-basin	7 10
Ditto Milk Ewer	4 10	Ditto Cream Ewer	5 10
Ditto Coffee-pot	15 0	Ditto Coffee-pot	15 0
Complete...	£38 6	Complete...	£40 0

A variety of upwards of 50 tea and coffee services may be seen in the show-rooms, where may be selected every article of silver requisite for the side-board or plate-chest. Pamphlets of prices, illustrated with sketches of the various articles, gratis, and forwarded, postage free, to any part of the kingdom.—A. B. SAVORY and SONS, 14, Cornhill, London, opposite the Bank of England.

DRESS AND FROCK COATS.

DRESS COATS, Superfine Cloth, 27s.; extra quality, 35s. and 40s.; Imperial Saxony, 50s.; Frock Coats, Silk Facings, 30s. to 40s., extra quality, Silk Velvet Collar, and Silk facings, 48s.; Saxony ditto, 55s.; Children's Silk Tunic and Hussar Suits, 30s.; Waistcoats, new patterns, 5s. 6d. to 10s. 6d.; Trousers, 6s. 6d. to 16s. 6d.; excellent Doeskin, 12s. to 16s.; Summer Coats, 5s. 6d. to 10s. 6d.; Chesterfield Over Coats, with Silk Collars and Cuffs, 15s. to 21s. The much approved new style, 21s. A suit of Black Cloth, 2l. 5s.; extra quality, 3l. 3s.; Imperial Saxony Suit, warranted to retain its colour, 4l. 4s., at FISHER and Co.'s, Tailors, 31, King William Street, City, 10 doors from London Bridge.

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of searching thoroughly into the divisions of the teeth, and cleaning them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose—1s. An improved Clothes Brush, that cleans in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and successful manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the luxury of a genuine Smyrna Sponge. Only at METCALFE'S Sole Establishment, 130a, Oxford-street, one door from Holles-street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

BURBIDGE AND HEALY'S COOKING APPARATUS, combining Sylvester's Patents.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship; in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B. & H. can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made. A Prospectus can be forwarded, upon application, detailing particulars and prices, to 130, Fleet-street.

SURPRISING EFFICACY OF "PARR'S LIFE PILLS."

Testimonial just received by the Hibernia from America.—Dr. C. STEANE, 184, Fulton-street, sole agent for Brooklyn, L.I.—An instance of the singular efficacy of PARR'S LIFE PILLS, which merits particular notice, occurred in the person of a lady, residing at Brooklyn, of consumptive make, who had been afflicted for upwards of six years with very great and nasal debility, headache, flatulence, faintings, and all the effects originating in an impaired constitution. Country air was tried, but to little advantage. She complained of weariness and pain on the least motion; her bowels were sometimes constipated, and at other times lax, and never regular. At this period, she was recommended to try PARR'S LIFE PILLS, when, no less astonishing than true, before she had finished two boxes, an entire and perfect cure was the result. To such, nothing can equal this antidote, as it imparts tone and strength to the stomach, and operates so mildly, that the most delicate of either sex can take them with the greatest safety.—Yours truly,

To T. Roberts & Co., April, 1844. C. STEANE.

These and hundreds of other cases of decided cures, attested on the highest authority, and already published, occupy upwards of 120 pages of letterpress. These Testimonials are published periodically, and may be had on application at any respectable medicine vendor's. The cures in many instances were effected after all other means had failed, and they thus establish the claims of PARR'S LIFE PILLS in being considered the best medicine in the world.

CAUTION TO THE PUBLIC.—Beware of spurious imitations of the above Medicine. None are genuine unless the words "PARR'S LIFE PILLS" are in WHITE LETTERS on a RED GROUND, engraved in the Government Stamp, pasted round each box; also the fac-simile of the signature of the proprietors, "T. ROBERTS & Co., Crane-court, Fleet-street, London," on the directions.

GLASS CHANDELIERS FOR DRAWING-ROOMS.—APSLEY PELLATT (late Pellatt and Green), Falcon Glass Works, Holland-street, Blackfriars, has recently constructed a NEW CHANDELIER (Registered), which surpasses in brilliant and refractive effects all former efforts, to which he invites inspection. Renaissance and other Glass Chandeliers as usual at low prices, which, when lighted, have a far more resplendent effect than bull. TABLE CUT AND ENGRAVED GLASS at the Printed List of Prices, subject to an extra discount for Cash. The manufactory and steam-cutting works may be seen any Tuesday, Wednesday, or Thursday. Merchants' orders and outfits for Glass and China on the very lowest terms. No connexion with any house in the City.

PRESERVES and CONFECTIONERY.—The superiority of BETTS'S PATENT BRANDY for PRESERVES and CONFECTIONERY, is testified by the fact that it is preferred to any other spirit by the most extensive WHOLESALE CONFECTIONERS in the METROPOLIS; for fortifying Home-made Wines it is invaluable; as an Ordinary Beverage it is congenial to the most delicate constitutions; and, as a Medical Stimulant, it is peculiarly adapted to persons of bilious or dyspeptic habits. Quantities of not less than TWO Gallons, supplied at the Distillery, 7, Smithfield Bars, in Stone Jars, at 16s. per Gallon, exclusive of the price of the Jar; and in Glass Bottles, at 22s. per Gallon, Bottles and Case included.

CONSUMERS of BRANDY are respectfully informed, that J. T. BETTS, JUN., and Co., will not be responsible for any BOTTLED BRANDY that is not protected against fraudulent substitution, by the PATENT METALLIC CAPSULES, made of pure and solid metal (not tin-foil), embossed with the words "Betts's Patent Brandy, 7, Smithfield Bars," in addition to the usual stamping.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6, 1844.*—The cable of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which it is found for every variety of dish, from turtle to beef, from salmon to sprats, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of the luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites, more wholesome and of less cost."—*Naval and Military Gazette, July 8, 1843.*

Sold Wholesale by the [illegible], Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

POTTS'S PATENT for HANGING PICTURES.—"Artis est celare artem."—It is seldom that this desideratum is so successfully carried out as in the above Invention by its combining an Architectural Cornice Moulding with means to suspend the largest Pictures. Specimens at Mr. NOTTINGHAM'S, 6, St. Bene't-place, Gracechurch-street.

INTERESTING TO LADIES.—To MESSRS. ROWLAND & SON, 20, Hatton Garden, London.—"Percy Place, Landport, Portsmouth, April 4, 1844. GENTLEMEN,—I think it but an act of justice to inform you of the benefit I have derived from the use of your admirable Macassar Oil. About six months ago I found my hair getting daily more weak and thin, and much discoloured from a practice I had adopted of wetting it continually; fearing that I should lose it entirely, and hearing of the efficacy of your Macassar Oil, I have for some time past constantly used it, and the result is, that my hair is now perfectly restored and much improved in appearance and colour, having become thick, dark and glossy; it also curls freely without the use of paper, which it never did before. To all my friends I have warmly recommended your Macassar Oil as an excellent restorative and preservative for the Hair. As I have an objection to see my name in print, I beg you will not publish it; but you are at liberty to show this letter, or make any other use you please of it, and refer applicants to me if necessary, in proof of the efficacy of your Macassar Oil. Your Obt. Servant *"

ROWLAND'S MACASSAR OIL preserves and reproduces the Hair; prevents it from falling off or turning Gray; changes Gray Hair to its original colour; frees it from Scurf and Dandriff, and makes it beautifully soft and curly.

*** Ask for "ROWLAND'S MACASSAR OIL." All others are Fraudulent Counterfeits.

This Day is Published, Price One Shilling,

A LECTURE ON INSTITUTIONS FOR THE BETTER EDUCATION OF THE FARMING CLASSES, especially with reference to the proposed Agricultural College near Cirencester, with some remarks on Experimental Farms, and on the class of inquiries for which they are more particularly designed, delivered at the Botanic Garden, Oxford, on Tuesday, May 14, 1844. By CHARLES DAUBENY, M.D., F.R.S., &c. Honorary Member of the Royal Agricultural Society of England, and Professor of Rural Economy at the University of Oxford.

Oxford: Printed by THOMAS COMBE, Printer to the University. Sold by JOHN HENRY PARKER; and JOHN MURRAY, Albemarle-street, London. 1844.

In 8vo, boards, with very numerous woodcuts, price 10s. 6d.,

LINDLEY'S ELEMENTS OF BOTANY,

STRUCTURAL, PHYSIOLOGICAL, SYSTEMATICAL, AND MEDICAL.

Being a Fourth Edition of the "Outline of the First Principles of Botany."

Contents of the Work—I. STRUCTURAL and PHYSIOLOGICAL BOTANY:—1, Elementary Organs; 2, Compound Organs; 3, Root; 4, Stem; 5, Leaf-buds; 6, Leaves; 7, Food and Secretions; 8, Flower-buds; 9, Inflorescence; 10, Floral Envelopes; 11, Male Organs; 12, Disk; 13, Female Organs; 14, Ovule; 15, Impregnation; 16, Fruit; 17, Seed; 18, Acrogens, or Flowerless Plants.

II. SYSTEMATICAL BOTANY:—1, Linnean Sexual System; 2, Analytical Method; 3, Natural System; 4, Natural System of De Candolle (*this Part illustrated with Numerous Figures of the details of the more important Natural Orders*); 5, the Affinances of Plants; 6, Sketch of a New Distribution of the Vegetable Kingdom.

NEW THUNBERGIAS.

JOSEPH FRYER begs respectfully to offer two very superb New SEEDLING THUNBERGIAS, which he has named Alata superba and Aurantiaca superba, and which he intends sending out the first week in August (free by post), at 5s. each, with allowance to the Trade, if three or more are taken. For description J. F. begs to refer to the following Editors' opinions:—Dr. Lindley, in last week's *Chronicle*—"J. Fryer.—If your seedling Thunbergias called Alata superba and Aurantiaca superba retain their increased size, they are certainly a great improvement." Mr. Glenny, in last week's *Gardeners' Gazette*—"Mr. Fryer's Thunbergias, Alata superba and Aurantiaca superba, are very decided improvements on the previous varieties. The roundness of the flower is remarkable, and shows what may be done by perseverance. The yellow and orange are both pure and pretty." Mr. Plant, in the "Florists' Journal" for December last, describes them as possessing the most symmetrical outline he ever saw, and forming a perfect circle—the segments of the limb overlapping to such a degree as to give the flower nearly the substance of two.

Clarendon Nursery, Camberwell, London, July 11, 1844.

THE BEST 24 VERBENAS EVER OFFERED, FOR 21s., OR 12 FOR 12s.

G. SMITH begs to offer the following splendid Verbenas, including all the choicest varieties of the season, which obtained the 1st Prize at the Royal Botanic Gardens of London, July 2; where they were much admired for their fine form and brilliant colours:—viz., Azurea grandiflora, Atro purpurea, Atro sanguinea, Beauty Supreme, Brilliant, Princess Alice, Celestina, Wonder, Queen of Whites, Mouceat, White's Surprise, Youell's Surprise, Blue Queen, Zutex, Excelsa, Delicata, Array, Striata, Speciosa, Princess Royal, Hialopeana, Orange Perfection, Pucilli variabilis, Modesty, Perfection, Elegance, Variegata, Ne plus Ultra, Ingramii, Renown, Stewartii, Ignescens, Sompenii, Howardii, Boule de feu. A remittance from unknown correspondents.

Tollington Nursery, Hornsey Road, Islington, near London.

CLARKE and CO. (late Henry Clarke), respectfully solicit the attention of Market-Gardeners and the Trade to the under-mentioned LIST of PRICKS of SEEDS, which will be in requisition shortly, and can be recommended.

Yellow & White China, and Smith's Yellow Noisette Rose	9 0		
Fuchsias, all the leading varieties, including Exoniensis, 9s. &	12 0		
Fine new Yellow Carnations, the pair	3 0		

Albion Nursery, Stoke Newington, London.

ORANGE and LEMON-TREES, 10s. each.—R. HALL begs to advise that he has just received his last importation of the above-named trees, varying from 10 inches to 4 feet in the stem, which he offers for sale at the low rate of 10s. each. They are in excellent condition, and full of leaf.—Oil and Italian Warehouse, 86, South Audley-st., Grosvenor-sq.

ROBERT HALL, Florist, Alkrington, near Middleton, Lancashire, begs to call the attention of Amateurs and Florists in general, to his first-rate Collection of AURICULAS and POLYANTHUSES, Catalogues of which may be had on prepaid application.—Alkringt n, July 8, 1844.

MUSA CAVENDISHII and SAPIENTUM.—Fine Plants of the above varieties, at 20s. each, to be had from Wm. Melville, Welcombe Gardens, Stratford-on-Avon, Warwickshire.

MAGICAL EFFECT ON FLOWERS.—*Gardeners' Chronicle*, April 27th.—"I cannot speak of POTTER'S LIQUID GUANO in adequate terms of praise. I tried it on Hyacinths, and other Flowers. The effect was magical. My flowers were the finest I ever beheld, and they preserved their beauty nearly double their usual time."—*W. Kidd, Hammersmith.*

"I write to describe the wonderful efficacy of POTTER'S LIQUID GUANO; Peas, Onions, and Asparagus have been singularly improved by it. People came to admire the appearance of the garden."—See *Chronicle*, p. 405.

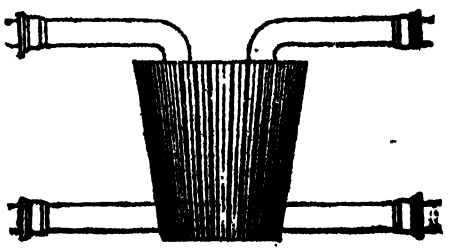
*** Beware of an inefficacious imitation. See *Chronicle*, p. 405—"Humphreys's Compound."

Sold by most Chemists and Seedsmen.
Factory, 28, Upper Fore-street, Lambeth.

BENTALLS' IMPROVED PAPER FOR DRYING PLANTS. W. and T. BENTALL, in soliciting the attention of Botanists to the above Paper, beg to submit to their notice the following, as one of the numerous Testimonials with which they have been favoured:—

"Gentlemen,—Though my trial of your new Botanical Paper has been short, I think it may safely be pronounced the best combination of the qualities required in such paper that I have hitherto met with, after trying several kinds, both British made and Foreign.

"It seems probable that your Paper will prove more serviceable to the Botanical traveller than the thick grey Paper often sent with specimens from Germany, and much esteemed by English Botanists; but having the serious defect of extreme liability to tear, which does not appear in your Paper. It certainly ought to supersede the demy Grey recommended in the Instructions issued by the Botanical Society of Edinburgh."—*H. C Watson, Esq., F.L.S., Vice-President of the Botanical Society of London.*



Professor Lindley, University College, London, & C. C. B. Babington, Esq., F.L.S., St. John's College, Cambridge, have also kindly allowed the use of their names as strongly recommending it.

May be had of the Manufacturers, Halstead, Essex; and of their agents, Mr. E. Newman, 9, Devonshire-street, Bishopsgate-street, London; and Mr. R. S. McIntosh, 12, Catharine-street, Edinburgh.

For Sizes & Prices, see *Gardeners' Chronicle*, June 8th & 15th.

LYNDON'S PATENT SPADE.—Sold by Green and Constable, Ironmongers, 36, King William-st., London-bridge. Horticultural Tool Chests, Bright Ladies' Spades, Money's Patent Water Pots, Lord Vernon's Patent Hoes, with a general assortment of Garden Implements.

BURBIDGE and HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.

Burbidge and Healy respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, Burbidge and Healy refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. Glendinning, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.		Patent Door and Frames.	Fire-bars & Dead Plate.		Flue Door.		Damper.		Will heat of Pipe.	Forcing Pit, Length by feet.
in.	ft	s.	s.	d.	s.	d.	s.	d.		
10	1	5	20	7	6	6	2	6	30 feet.	12 to 20
Ribbed Boiler.										
10	2	2	20	10	6	7	2	6	50 to 70 ft. 4 in.	Under 25 to 40
12	2	15	30	12	6	7	3	6	90 to 125 feet.	40 to 65
14	3	10	35	17	5	8	4	6	150 to 200 feet.	65 to 100
18	5	5	42	25	0	8	5	6	300 to 400 feet.	Warm a grapery 25ft. long, and a pit 50ft.
24	8	15	56	35	0	8	6	6	500 to 800 feet.	

If 3-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

CHOICE FLOWERS AND PLANTS IN POTS.

HUMPHREYS'S SOLUBLE COMPOUND.—A few grains occasionally dissolved in the water used with Plants produce a vigorous growth and splendid flowers. If what is called a "*Liquid Guano*" is desired, a superior article is obtained at half the usual cost, by dissolving Half a Bottle of this powder in a *quart of water*, and using a table-spoonful to a gallon in watering flower-beds. *Sold in bottles*, 1s. 9d. *each*, by Chemists and Seedsmen. Agents, Davy, Mackmurdo and Co., 100, Upper Thames-street, London.

*** "In these days of *deception*, it is due to those persons who send out a really good article, that those who benefit by it should make it known."—See Evidence of J. R. Pearson, Chilwell Nurseries, *Chronicle*, p. 390, "*Humphreys's Compound.*"

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. Bailey also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. Bailey were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON and CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. Mr. Rendle, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS and SONS, LONDON; Wm. J. MYERS and CO., LIVERPOOL;

And by their Agents,
COTESWORTH, POWELL, and PEYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, July 13, 1844.

TURNIP SEASON.

GUANO (Foreign and Potter's), RAPE-DUST, BONE-DUST, CLARKE'S COMPOST, and all other MANURES for the TURNIP CROP, to be had on the best terms, of Mark Fotheringill, 40, Upper Thames-street.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, June 12, 1844:—

Bones	p. ton £4 10s. 0d	Nitrate of Potash	,, £1 4s. 6d
,, crushed,	£1. 10s. to 6 0 0	Oil of Vitriol, or Sulph. acid	p. lb. 0 0 1
,, calcined	7 0 0	Rape Cakes	p. ton 4 15 0
Carbonate of ammonia	p. cwt. 3 10 0	Salts, Epsom	,, 9 0 0
Guano, Peruvian,	p. ton 11 0 0	,, Glauber	,, 7 0 0
,, Ichaboe	,, 9 0 0	Sulphate of Ammonia, per cwt.,	16s. to 0 17 0
Gypsum	,, 2 5 0		
Nitrate of Soda,	p. cwt. 0 14 0		

Wm. Northcott, 13, Rood-lane, Fenchurch-street.

GUANO.—For Sale, in bags of 1 cwt. each; just landed, with a succession of cargoes to arrive.

There being considerable variety in the qualities of Guano imported from different places, and indeed from the same island, each parcel will be chemically analysed with the utmost precision, to show its relative productive power. A copy of such analysis will be given to buyers, and also instructions as to the most approved mode of using the Guano, furnished by the experience of eminent Agriculturists in England and Scotland.

Large parcels will be delivered direct from the ship, or waterside premises. Smaller quantities may be had at the warehouses, 24 and 25, Billiter-street; or delivered within any reasonable distance, at a trifling additional cost.—Apply to JAMES CLARK, 24, Billiter-street

TURNIP SOWING. — BRAIN'S ENGLISH GUANO MANURE.—This powerful Manure having been subjected to the most rigorous Analysis by some of the first Agricultural Chemists of the day, it is pronounced by them to be much stronger, and to possess more highly fertilising properties, than the very best samples of Guano brought to this country. Price 9*l.* per ton, no charge for sacks, and delivered free of charge to any wharf, railway or waggon office in town.—Address, FREDERICK BRAIN, Guano Works, Thomas-street, Stamford street, Blackfriars-road, London.

N.B.—Directions for use sent with all orders.

TURNIPS, &c.

DR. HALLETT'S DRY SOLUBLE FERTILISERS are composed of all the useful ingredients of the best Foreign Guano, which manure is already nearly exhausted, and no two parcels of which were ever alike. They contain also other ingredients equally useful, and are always to be produced of uniform strength; they are improvers of all soils, but most so of poor ones, and cannot possibly prove injurious to soil or crop, as they contain no heating or caustic materials, being simply and purely Fertilisers. Five cwt. of either of them is equal to nearly 30 tons of horse-manure as a Fertiliser. They are used, the one for all the varieties of Corn, Peas, Beans, Chicory, &c., and the other for Turnips, Mangold Wurzel, Natural and Artificial Grasses, and all Gardening purposes. This is the best protector yet discovered against the Fly in Turnips, for it gives a first growth three weeks beyond that of any other known manure. *Price of each Fertiliser*, 10*l.* per ton, or 12*s.* per cwt.

Sold by Mr. FOTHERGILL, 40, Upper Thames-street; and Mr. G. HALLETT, at the Factory, Broadwall, Blackfriars, London. The Fertilisers are manufactured under the immediate inspection of J. J. HALLETT, M.D., &c.

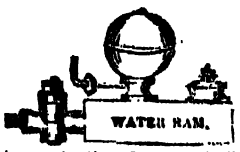
Agents for London, Messrs. WINSTANLEY, Chemists, 7, Poultry; Suffolk, Mr. W. REVANS, Yoxford, Norfolk, Messrs. BULLARD and WATTS, Norwich; Jersey, Mr. C. Kruger. Respectable country agents wanted.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1*d* per foot, super. A discount to the trade. THOS. J. CRODDON, 8, Ingram-court, Fenchurch-st., London.

IMPORTANT to AGRICULTURISTS.—ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), with the view of ascertaining whether the soil on which it is proposed to grow any particular crop contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general.



Gentlemen Instructed in Agricultural Chemistry; the Course will comprehend the Elements of Analysis.

No. 5a, Hawley-road, Kentish Town.

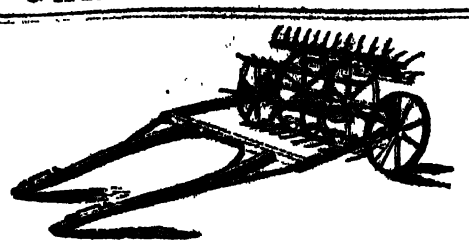
70, STRAND, LONDON.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

TANNER'S VITREOUS FLUID and CLOTH, a Substitute for Glass for Horticultural Purposes.—The Vitreous Cloth proves its superiority over Glass, by producing the light most suitable to vegetation, superseding the necessity of any shading, preserving a healthy moisture on the plant, retaining its bloom to a more lengthened period, less expensive, and not requiring so much attention. The above (retaining heat) is preferable to glass for Hothouses, &c., the temperature of which is maintained with less fuel. It is equally applicable as a covering for Fruit trees, preserving them from frost, blight, and excessive heat. The Vitreous Cloth, made by machinery, is much superior to any prepared in a different manner. By the use of the Vitreous fluid, the Cloth (after lengthened service) may be renewed.

The Fluid sold in bottles 2*s.* 6*d.* and 4*s.* 6*d.* The Cloth 2*s.* 6*d.* and 3*s.* per yard. Manufactured by N. W. TANNER, Chemist, Exeter. Agents for Exeter and Vicinity, Messrs. LUCOMBE, PINCE, & Co., Exeter Nursery.



To Mr. N. W. Tanner—Sir, we have used your prepared Cloth, and have pleasure in informing you that whilst the light admitted through it is very suitable to vegetation, there has been no necessity to have recourse to any extra shading during the very clear, bright weather which we have so long experienced; this we consider an important point. Yours, &c.

(Signed) LUCOMBE, PINCE & Co., Exeter Nursery.

June 21, 1844.

*** Respectable Agents required.

WRIGHT'S STACK PRESERVER.—Hundreds of Stacks of fine Hay were saved from spontaneous combustion or discoloration in the neighbourhood of the inventor, by the use of the above invaluable instrument. The article may be seen, and bills obtained, containing testimonials to its value from experienced Farmers who have for many years proved its efficacy, at J. WRIGHT'S, Manufacturer, Ongar, Essex; J. and G. BRAIN, Ironmongers, London-bridge; and of any Ironmonger in the country. Price, in box, with lock and joints, 2*l.* 5*s.*

HAYMAKING SEASON. — Agriculturists, and others who may require the assistance of WEDLAKE'S PATENT DOUBLE-ACTION HAYMAKING MACHINE, are requested to send their orders early to the London Depôt, No. 118, Fenchurch-street, opposite Mark-lane, where one of the Machines may be inspected.—Catalogues of Agricultural Implements and Machinery may be had on application.

YORKSHIRE AGRICULTURAL SOCIETY.

The EARL OF ZETLAND, PRESIDENT.

THE SEVENTH GREAT ANNUAL MEETING and EXHIBITION of the above SOCIETY will be held at RICHMOND, on WEDNESDAY, August 7th, 1844, when about SIX HUNDRED POUNDS will be offered in Prizes for Stock, Implements, Essays, Drain Tiles, Cheese, &c.

No articles can be admitted for Exhibition or Trial unless a Certificate of Entry be filled up according to the prescribed form, and sent by Letter, (not delivered), to the Secretary, MATTHEW M. MILBURN, of Thorpfield, Thirsk, on or before WEDNESDAY, July 24th. Lists of Prizes and Forms of Certificate may be had, free, on application by Letter, to the Secretary.

For the convenience of persons to whom it may be inconvenient to write to the Secretary, Mr. JOHN WATSON, of 1, Clarence-street, York, and H. J. TURNER, Esq., of Richmond, will also receive entries and transmit them to the Secretary, but all entries made to them must be at least One Day before the 24th July.

Members of the Society exhibit all articles Free. Non-Members pay 10*s.* for every article or lot of articles, before they obtain their Ticket of Admission to the Show Fields. Persons become Members of the Society by the payment annually, in advance, of a Subscription of 1*l.*, on application to the Secretary, who will be glad to give any information respecting the Society or its meeting.

By Order of the Council, MATTHEW M. MILBURN,
Thorpfield, Thirsk, July 1st, 1844. Secretary.

AGRICULTURAL COLLEGE, &c.

AT a GENERAL MEETING of the Subscribers and Friends of the proposed AGRICULTURAL COLLEGE, held at CIRENCESTER, the 1st of JULY, 1844, EARL BATHURST in the Chair, the following Resolutions were unanimously carried:—

First—Moved by T. H. S. SOTHERON, Esq., M.P., and seconded by EDWARD HOLLAND, Esq.—That it appearing by the Report of the Committee appointed at the last General Meeting that the establishment of an Institution for giving a scientific and practical education to young persons intended for Agricultural pursuits, will receive adequate support: *Resolved*, that the present Subscribers, and those who may hereafter become subscribers, until the whole capital shall be subscribed for, constitute a company to be incorporated by Royal Charter, limiting individual responsibility, for the establishment of such an Institution.

Second—Moved by JAMES CROWDY, Esq., and seconded by Dr. DAUBENY,—That the affairs of the Company shall be carried on by a President, Vice President, and Committee of Management, which is hereby authorised to apply for a Charter, and to arrange with Earl Bathurst the lease of the Farm; to call in Subscriptions, and to be invested with full powers to act in other respects; to consist of 18 Shareholders, five to form a quorum, and one third of the number to go out annually, by rotation, but to be re-eligible; and that the following form the Committee:—

Earl Bathurst,	Charles Lawrence, Esq.
T. H. S. Sotheron, Esq., M.P.	Rev. Thomas Maurice
Edmund Holland, Esq.	Mr. Daniel Tinder
Sir M. H. Hicks Beach, Bart.	Mr. Edward Bowly
Raymond Cripps, Esq.	Mr. Edmund Rack
Rev. J. M. Prower	Mr. James Kearsey
Mr. Henry Howell	Mr. Thomas Stone
Mr. Peter Matthews	Mr. Thomas C. Broan
Mr. T. Arkell	Mr. Thomas Iles.
Dr. Daubeny	

Third—Moved by the Rev. J. M. PROWER, and seconded by Mr. KEARSEY,—That Earl Bathurst, Earl Ducie, T. H. S. S. E. Sotheron, Esq., and Edmund Holland, Esq., be the Trustees of the Institution.

Fourth—Moved by Mr. A. R. FEWSTER, and seconded by Rev. T. MAURICE,—That the Council of the Royal Agricultural Society of England having given their sanction to the holding of a Meeting during the Session at Southampton, for the purpose of making the objects of this Institution more generally known amongst Agriculturists: Resolved, that a Meeting be held on the evening of Tuesday, the 23d instant, at Southampton, and that the Committee appoint a Deputation to call and attend such Meeting.

Fifth—Moved by Mr. EDWARD BOWLY, and seconded by Mr. CHARLES LAWRENCE,—That Earl Bathurst be President, the Earl of Ducie, Vice-President, and Mr. Robert J. Brown, Honorary Secretary, to be ex officio members of the Committee.

Sixth.—It was Resolved unanimously—That the thanks of this Meeting be given to Earl Bathurst, for taking the chair.

REPORT OF THE COMMITTEE.

The Committee report that in pursuance of the resolution in that behalf passed at the General Meeting, they have by public Advertisement and otherwise, invited Tenders of a suitable Site for the proposed College. They are happy to inform the Meeting that they have received the offer of a Farm on Lease from Earl Bathurst, which, from its general character and situation, is, in their opinion, so well adapted for the purposes of the Institution, that they have no hesitation in recommending that an application be immediately made to his Lordship for the terms on which he would be willing to let the Farm. The Committee have every reason to believe the terms would be entirely satisfactory to the Subscribers. They have great satisfaction in reporting further a very handsome offer on the part of Earl Bathurst, to advance at very moderate interest, to be added to the rent, one half, not exceeding 2000*l.*, of the expense of the necessary buildings.

This Farm now consists of about 400 acres of arable, and 30 acres of pasture land, and is situated about one mile from Cirencester, and accessible by two good turnpike-roads.

The Committee are further enabled to report that the application for a Charter has been so favourably received by Government as to leave no doubt that one will be granted, provided the Society consent that any surplus of income, after paying dividends at the rate of 4 per cent. on the subscribed capital, shall be applied to increase the efficiency of the Institution.

The Committee continues to receive such increasing support and encouragement, that with the aid of the fund for building offered by Earl Bathurst, they are of opinion that all necessary steps for the establishment of the College may at once be safely taken. (Signed) RAYMOND CRIPPS, Chairman.

Cirencester, 1st July, 1844.

YORKSHIRE LAND-DRAINING ASSOCIATION.—At a MEETING of the PROVISIONAL COMMITTEE held at YORK, this day, for the purpose of Allotting the Shares applied for in the Association, and on other business—

It was resolved that the number of Shares now allotted being amply sufficient to justify the Committee in proceeding forthwith to carry out the objects of the Association, the necessary Deed of Settlement be prepared for execution. And that such of the Public as may yet be desirous of becoming Shareholders, and shall signify the same to the Solicitors (Messrs. BLANCHARD, RICHARDSON, and GUTCH, York), or to the Secretary, (Mr. CHARNOCK, Wakefield), on or before the 31st of July next, shall be admitted (if the number of unallotted Shares be sufficient), on the same terms as the present Subscribers.

York, June 12, 1844. JAMES HAMERTON, Chairman.

AGRICULTURAL SCHOOL.

MESSRS. NESBIT'S ACADEMY, 38, Kennington-lane, Lambeth, near London.

"From Chemistry alone further progress in Agriculture is to be expected."—LIEBIG.

In this School, in addition to the general routine studies, every facility is afforded for the acquisition of a sound knowledge of Chemistry. The Pupils are practically taught in the Laboratories the methods of analysing the various earths, soils, manures, &c.; and likewise the means of detecting the substances abstracted from the land by different crops. Land Surveying is also taught practically, as well as theoretically.

A copy of a Lecture on Agricultural Chemistry, delivered by Mr. J. C. NESBIT to the Maidstone Farmers' Club, and the Terms of the School, which vary from 40 gs. to 70 gs. per annum, may be had on application, either personally or by letter.

Mr. NESBIT'S Works on Land Surveying, Mensuration, Gauging, Arithmetic, English Parsing, Education, &c., may be had of all Booksellers.

REFERENCES.—Dr. D. B. Reid, F.R.S.E., &c., Author of "Elements of Practical Chemistry," &c., St. James's Park, Westminster; G. F. Richardson, Esq., F.G.S., Author of "Geology for Beginners," &c., British Museum, London; W. and J. Gibbs, Esqrs., Civil Engineers, Devonshire-street, Portland place, London; Rev. T. Cuffe, Carlisle Episcopal Chapel, Lambeth; R. Grecnhill, Esq., Ashford, Kent; and C. G. Whitaker, Esq., Barming, near Maidstone, Kent.

The School will be re-opened on Monday, July 15th, 1844.

ROYAL AGRICULTURAL MEETING AT SOUTHAMPTON.

THOMAS MATCHAM, of the ROYAL HOTEL, Southampton, being the sole appointed Agent for the London and South-Western Railway Company, begs to inform those parties who intend sending Cattle or Implements for the approaching Agricultural Show, that he will be in readiness at the Railway Terminus and the Portswood Station to convey Implements and Cattle to the Show-yard at very moderate charges, particulars of which may be obtained upon application at the Terminus of the London and South-Western Railway, Nine Elms and Southampton. T. MATCHAM requests—to prevent disappointment—that due notice may be given him, with full particulars of what each party may require. Omnibuses, Flys, and Post horses will be in readiness at the Terminus to meet the Trains for the conveying of Passengers to the Show.

DRAWING-ROOM CLOCKS.—A. B. SAVORY and SONS, No. 9, Cornhill, London, opposite the Bank of England, invite attention to a splendid variety of Rosewood, China, Bronze, and Ormolu CLOCKS; they go for eight days and strike the hours and half-hours. Price 4 guineas, 7 guineas and 10 guineas each, and upwards. The performance is warranted.

A Pamphlet, with detailed lists of Prices, and illustrated with sketches, may be had on application gratis, or sent to all parts of Great Britain and Ireland, postage free, in answer to a post letter.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June* 6, 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS's Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its cephal flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 6, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

PAXTON-PLACE, NEAR ST. NEOTS.

TO BE SOLD BY AUCTION, by WM. MEDLAND, on MONDAY 22d, WEDNESDAY 24th, and FRIDAY, 26th days of JULY, 1844, by order of the Executors of the late H. P. STANLEY, Esq., 2530 GREENHOUSE, ORCHIDACEOUS, and other Hothouse PLANTS; Three Superior GREEN and HOTHOUSES, 52 MELON and CUCUMBER LIGHTS, and 265 Dozen of CHOICE WINES.

ARRANGEMENT.—On Monday 22d: 1926 Greenhouse, 328 Orchidaceous, and 574 Hothouse Plants and Cape Bulbs, at Ten o'clock. On Wednesday 24th, 1000 Greenhouse Plants and Bulbs, and the Hot and Greenhouses, and Melon and Cucumber Lights, at Ten o'clock. On Friday 26th, the Wines, comprising 192 doz. Port, 80 doz. Sherry, 80 doz. East India Madeira, 11 doz. Claret, 14½ doz. Hock, 20 doz. Champagne, and other Wines, at One o'clock.

Catalogues may be had at the George, Huntingdon and Bedford; Eagle, Cambridge; Unicorn, St. Ives; Swan, Biggleswade; Three Cups, Aldersgate-street, London; and of WM. MEDLAND, Surveyor and Appraiser, St. Neots.

TO CAPITALISTS.

TO BE SOLD, to pay a clear Five per Cent., THE TOLLS arising from the Navigation of Vessels laden with Corn, Coals, Timber, Stone, &c. &c., passing along the River Waveney, from Beccles to Bungay, Suffolk, with a Capital Residence, Malting Office, Business Premises, &c., at Bungay.

The above Property is let on Lease at 1300*l.* per annum, six years of which Lease were unexpired at Lady-day last.

For Price and further Particulars apply to Mr. BUTCHER, Auctioneer, Norwich.

VALUABLE CHURCH PREFERMENT.

TO BE SOLD, the NEXT PRESENTATION to the RECTORY of RICKINGHALL INFERIOR, in SUFFOLK. The Incumbent is in the 68th year of his age, and the Net Income arising from the Commuted Tithes, Glebes, and Surplice Fees, average about 468*l.* per annum. Also, the NEXT PRESENTATION to the RECTORY of RICKINGHALL SUPERIOR, possessing a Net Income of 438*l.* per annum.

For further particulars apply to Mr. BUTCHER, Auctioneer Norwich.

CARNATIONS AND PICOTEES.—Grand Exhibition now in full bloom, at Messrs. N. & B. NORMAN'S, Bull Fields, Woolwich. July 6, 1844.

GRAND FLORAL FETE & HORTICULTURAL EXHIBITION, will take place in the Rosherville Gardens, Gravesend, on WEDNESDAY, July 17th, 1844, when Prizes to the extent of 50*l.* for the best productions will be distributed. Two full Military Bands will be in attendance, and the Evening's amusements will conclude with a brilliant display of Fireworks. The Gardens will be opened to the Public at 12 o'clock. Admission, 1*s.* each.

The Gardeners' Chronicle.

SATURDAY, JULY 13, 1844.

MEETING FOR THE TWO FOLLOWING WEEKS.

TUESDAY, July 23 South London Floricultural . 1 P.M.

A CORRESPONDENT has sent us the following statement concerning the JUDGES at the last ROYAL BOTANICAL SOCIETY'S Show in the Regent's Park. He complains of two things. The first is, that two or three Nurserymen were appointed to judge the Amateurs' Roses, and three Amateurs to judge the Nurserymen's in return, nearly all of whom were themselves exhibitors; so that, in fact, each party judged the other's Roses The second allegation is, that although one Nurseryman was disqualified, in consequence of having too many stems in several of his varieties, yet another Nurseryman, exhibiting two Roses without names, and two others of the same kind with the same name, received a prize; an extra prize, on the other hand, was, he says, awarded to an Amateur who had fallen into the same error which disqualified the Nurseryman. This method of judging he complains of as unfair; and very justly, IF TRUE.

But upon making inquiry, we find that, as to the first allegation, no Nurseryman whatever was among the judges of Roses, nor were there two sets of judges for those flowers; so that the first statement is altogether a mistake, and requires no further comment. The second charge is answered by the judges thus:—There was but one Nurseryman's stand that did not, as far as the judges could discover, comply with the regulations, and that one was otherwise inferior, in their opinion, to those which received prizes. Not one of the Amateurs complied with the regulations, and therefore the judges had to decide whether they would refuse prizes to the whole of them, or, as they were all alike in error, determine their merits without reference to the regulations. They decided upon the latter course—and they did right.

Our correspondent adds that "Fair play is a jewel;" and we entirely agree with him. He too will, we trust, agree with us in thinking that, as other persons are, no doubt, under the same misapprehensions as himself, this mode of noticing his communication is more in the spirit of that good old English maxim, than the insertion of it, without comment, would have been.

THOUGH HYBRIDISING has already led to important results, they are probably nothing compared to what may be expected to come of it. We anticipate through its assistance a change in the whole face of cultivated plants, and we shall be much surprised if even a few years do not bring us acquainted with races of trees, esculents, corn, and forage plants, of at least as much importance in their way as those which have already appeared among fruits and flowers; all that is wanted is to call attention to the subject, and to point out what the principles are which the experimenter has to bear in mind.

The effect is produced by applying the pollen of one flower to the stigma of another. The pollen indicates the male parent, the stigma the female. In performing the operation it is necessary to use these precautions:—The female flower must be deprived of her stamens before they burst and disperse their pollen; and as soon as the stigma is glutinous enough to hold it fast, the pollen must be applied with care. Should this care not be taken the stigma is very likely to be inoculated with the pollen of her own or some other flower, and then the pollen which it is intended to use will not take; for it must be always borne in mind that a stigma once inoculated cannot be inoculated again. From want of these precautions, people are continually fancying they have obtained hybrids when they have only gained natural seedlings. At least half the specimens of so-called hybrids sent to us for examination, are not hybridised at all. When the Dean of Manchester, who is the greatest of all authorities in this matter, wishes to obtain a cross, he always endeavours to force the female parent before others of its kind blow, so as to be insured against accidental inoculation from pollen floating in the air. Want of attention to these minutiæ has led to some singular errors on the part of a very ingenious correspondent, who fancied he had obtained seedlings between Crinum, Ismene, Buphane, Calostemma, &c., while he had only raised the usual seedlings.

It is hard to say within what limits the operation may be successfully practised. The general rule is that plants only, which are very nearly related, are able to inoculate each other. But there may be exceptions to this. At least we know that very near connexions have, or seem to have, a great aversion for one another. For example, a Raspberry and a Strawberry are first-cousins, yet they appear to have no mind for an alliance. A Gooseberry, Currant, and Black Currant are still nearer to each other, and their repugnance seems invincible; at least nobody has yet found means to hybridise them with each other, though many have attempted it. On the other hand, Heaths, different as they are from each other, intermingle freely; Cereus speciosissimus is readily inoculated by the night-flowering Cereus; and even the creeping Cereus has been crossed with the former; the Rhododendron will fertilise the Azalea; and, strangest of all, the Red Cedar has on several occasions been found to inoculate the American Arbor Vitæ, the issue from which is that curious whipcord-branched plant called in the gardens Thuja filiformis. This singular shrub was so produced for the first time in Messrs Loddiges' nursery at Hackney, and has since been obtained in the same manner at Paris. These facts open a very wide field for inquiry, and are especially valuable as affording evidence that the limits of hybridising are far from being narrow.

In the midst of many experiments conducted without exactness, from which no safe conclusion can be drawn, there are some which, in the hands of such men as the Dean of Manchester, seem to justify the important inference, that as a general rule the properties of the male parent will be most conspicuous in the hybrid. For example, Mr. Herbert crossed the long-yellow-cupped common Daffodil, with the small red-edge-cupped Poet's Daffodil; and the seeds of the common Daffodil furnished a bulb with most of the attributes of the Poet's Narcissus. The same gentleman also obtained out of a capsule of Rhododendron ponticum, inoculated by Azalea pontica, seedlings which had entirely the habit of the latter or male parent.

In like manner the arborescent crimson-flowered Rhododendron atlaclerense was raised from the seed of the dwarf pallid R. catawbiense hybridised by the arborescent crimson R. arboreum; and when the common scarlet Azalea, with its crimson flowers and narrow leaves, was inoculated at Highclere by Azalea pontica, Mr. Gower found that its seeds produced plants much more like the male than the female parent. Exceptions, or apparent exceptions to this, do no doubt exist, and hybrids could be found who are either half-way between their father and mother, or more like the mother than the father; but as far as any means of judging at present exist these would seem to be the exception and not the rule; and therefore the greater influence of the male may be taken as a tolerably safe guide in all experiments upon this interesting art.

IN resuming the important subject of the SCALE INSECTS infesting the Orange plantations in the Azores, and elsewhere, it may be observed that there are two others, of the same family, which affect those trees. The most formidable one is named Coccus Hesperidum, which we have frequently observed on the under side of the leaves of the Lemon and Citron, as well as of the Orange; and in greenhouses it is said these scales will attach themselves to Myrtles also, when they are kept rather warm. This animal is covered with an elliptical shield, which is inseparable from it, and of a deep brown colour, with a pale margin. It is a difficult pest to exterminate; and although many modes have been suggested, the best will not succeed, unless applied with care and perseverance. Lime and Tobacco-water may be thrown with the syringe upon the under sides of the leaves, the worst of which must be cut off, collected into baskets, and immediately burnt. This should be done at the coldest period of the year, when the young are inactive; for we have seen them running about as late as November in a greenhouse. We would also recommend a decoction to be made of shag Tobacco and water, say 1 lb. to a gallon, in which the leading shoots, when affected, should be immersed; and by repeating the experiment, it may be ascertained at what degree of strength and heat this liquor may be used, so as not to injure vegetation, and yet destroy the animals.

There is found also upon the Oranges, especially attached towards the crown and around the stalk, a smaller oval scale; it is of a brownish colour, and something like an oyster-shell when magnified, being slightly convex, with the anterior edge pale and membranous. It adheres very closely; and those which we removed left a whit spot beneath. Under one of these scales we found a fleshy Orange-coloured female, with eight or ten shining eggs, of an oval form, and a Lemon-colour. The mother was firmly fixed by her rostrum, which is more slender than the finest hair; and it was inserted into the skin of the fruit with such force, that it was with difficulty we could remove her. Beneath another scale were two or three smaller ones, which had been formed by the young under their parent; for, on removing these minute scales, which were bright brown on the disc, little females were disclosed, similar in colour to the eggs. It is not a little remarkable that these are a totally distinct species from that which inhabits the leaves; indeed, they belong to different genera. The leaf-scale, having the shield attached to the animal, is arranged under the Linnean group called Coccus; whilst that on the fruit, as we have just shown, is not attached to the scale, which forms a distinct shield; and this structure characterises the genus Aspidiotus.

It is fortunate that little need be apprehended from this scale; for no remedy but the destruction of the fruit could avail in its extirpation. But should it ever make its appearance in any numbers, it will be advisable to gather the affected fruit at once and burn it.

Those who are desirous of becoming better acquainted with the habits of these insects will find the economy, &c. of several species discussed in last year's *Gardeners' Chronicle*; but we may here state, that the males of the three species of Coccidæ infesting the Orange-trees are, we believe, unknown to naturalists. They are no doubt exceedingly minute, with two little white wings and two tails, similar to those of Coccus Aceris, figured in Curtis's Brit. Ent., pl. 717. It would be of essential service to destroy these gentlemen, in order to prevent the fertility of the females; and, since our first notice of the subject, it has occurred to us, that if the application of any of the adhesive paintings of clay, marl, &c. did not destroy the old females, which might escape the operation of scraping, from being stationed in the forks or upon young branches, still they would, if done in a workmanlike manner, prevent the young, possibly, from hatching, or at least from seeking fresh spots for subsistence; and if this end only were accomplished, the Mussel-scale must disappear the following season. We also think that the delicate males would be sealed up in their cocoons, from which they issue backwards.

Having thrown out these hints regarding the different species of scales which affect the Orange-trees, it only remains for us to observe, that as one of the most important uses of the *Gardeners' Chronicle* is to direct the attention of its readers, who have leisure and opportunities, to the most effective modes of destroying noxious insects, we trust that such as have Apple and Pear-trees affected by the Aspidiotus conchiformis will try experiments, and communicate them through this channel, by which means they may assist materially in saving the Orange-groves of the Azores.—*R.*

FRENCH CULTIVATION of the PELARGONIUM

(*Continued from page* 443.)

Propagation.—This is usually effected in two ways—by seed, and by cuttings; the last mode is practised to preserve the choice varieties, and the other to obtain new ones; for it is not to be supposed that the seed will produce plants similar to those from which it is taken: that scarcely ever happens. Cuttings are generally taken when the plants have ceased flowering, when they must be cut down to the second or third leaf above the shoot of that year. Strip off two or three leaves from the lower part, and the stipules, or little leaves, which are at the bottom of the stem; the cutting should be cut across immediately under a joint, then planted in a small pot with the soil well pressed around it, but not so as to hurt the bark. The watering-pot, if the earth be damp, will not be required, otherwise, a slight watering will be necessary; after which they must be left to dry in the open air, then placed under a frame upon a hotbed, and shaded whenever the sun shines on them. In a month or six weeks, they will have taken root, and must then be exposed to the air, by opening the top of the frame; at night they should be left entirely uncovered; and when sufficiently accustomed to the open air, they should be put into beds in an open situation, in order to make them hardy and strong. When the fibres have lined the sides of the pots like network, they require to be put into larger pots, in which they may remain until the general time for repotting. There are two other modes of taking cuttings, which succeed at least as well. A border being well dug, pulverised, and raked, lines are to be drawn at the distance of five or six inches from each other; the cuttings prepared as described are then planted in rows, and the name of each variety is painted on small wooden or lead labels. The planting finished, drive into the ground at each end a small wooden fork, and lay a stick across them, to support a mat to shade the cuttings from the sun. After ten days or a fortnight the matting should be put on later in the morning, and taken off earlier in the evening, and it should never be spread in rainy weather. In pots five or six inches in diameter, plant four or five cuttings around, an inch from the sides; water them very gently, and then range the pots under the shade of a

hedge or wall, taking care that no drops from it fall upon them; by those methods very few cuttings are lost, because though they may be exposed to much rain, the evaporation is greater in the open air than in a house, where, though the confined heat and moisture would cause them to take root quickly, those agents of vegetation would also occasion their decay. Though cuttings may be taken at all seasons, with the requisite precautions, the months of June, July, and August, are the most favorable.

Increase by Grafting.—If you wish to have two or three different varieties on the same stem, choose a plant with the same number of branches that you wish to have of colours. Cut off the tops of these branches the evening before they are grafted, as low as possible; and when the excess of sap has evaporated through the incisions, select an equal number of strong grafts (from stocks of equal vigour, so that there be an evenness and uniformity in the parts of the plant), from 9 ins. to 10 ins. in length; insert them in the incisions, bind them with soft ligatures, cover them with fresh Moss, and place them under a bell-glass shaded from the sun until the grafts have taken well.

Saving the Seed.—The seed must be gathered gradually as it arrives at maturity; for since all the flowers do not blossom at the same time, the seeds will not ripen simultaneously. You may know when to collect them by the brown colour of the upper part of the pod; the pod then becomes detached from the calyx, and if not carefully watched, may be carried away by the wind. The seeds should be put into paper bags and kept in a very dry place, until a sufficient quantity has been collected. Those which are collected at hazard may sometimes produce good varieties, but those from choice plants are far preferable. Seed may be raised so as to produce plants participating of the nature of two different stocks. Suppose two Pelargoniums in flower, of different colours, and that it is desired to have these two colours united in the same flower: to effect this combination, it is only necessary to cut out the stamens of that which you intend to become the parent, then take a small camel's-hair brush, and remove with it as much as you can of the pollen to the stigma of the mother plant, using great caution lest that organ be injured. The stamens may also be cut as fast as they ripen, and the anther applied to the pistils of the flowers that are to be fertilised. You must operate upon flowers equally advanced, or repeat two or three times this operation, in case the pistil is not fertilised the first time. In order to render the operation (which ought to be always repeated) more complete, the fertilised plant ought to be kept apart from every other, and covered with gauze, to protect it from bees and other insects, which would extract the nectar; but seed may be obtained which will give excellent varieties, without taking all this trouble, provided it be taken from flowers of first-rate merit.

ON GATHERING FRUITS.

THIS is a most important point to be attended to; for, upon the manner in which fruits are gathered depends the success of their keeping, in whatever manner they may be preserved. No fruits should be gathered when dew is upon them, or in dull, cloudy weather. On this important point every gardener agrees. I cannot too severely condemn the mode of gathering the more common fruits, as Apples and Pears, at one sweep; although a common practice, even with the best of gardeners, it is a bad one. All fruits should be gathered as they arrive at maturity, and that in the most careful manner. It, however, often happens, even in the most congenial climates and situations, that a portion of the fruit, of the same tree, and even on the same branch, will arrive at maturity sometimes before the others; the ripe portion should be gathered immediately, and carried carefully to the fruit-room, which should be cool and dry. Here they may be laid upon the shelves, or tables, as the case may be, and covered over with canvas, to prevent evaporation, and to keep the dust from settling upon them, whilst the remainder is gathered, when the whole should then be immediately packed for preservation.

There have been many plans recommended for gathering the more delicate fruits, of which I entirely disapprove. What I would recommend is to gather them by the hand in as careful a manner as possible, and lay them gently in baskets, previously padded and lined with some soft material, such as wadding, and carried without delay to the fruit-room; the shelves should be previously covered with canvas, or some such material. In good gardens, I would recommend that the fruits which are in any way difficult of being detached from the tree, should be cut of the twigs with a pair of sharp scissors, into a padded basket held beneath for their reception. This may be considered to be a tedious way of gathering fruits; I grant it is. But if we consider, we will see that the fruit thus carefully gathered will repay the trouble, by keeping longer fresh and sound. I can boldly assert, that there is more fruit injured by improper gathering and storing, than by any other means.

In proof of this, if gardeners would take an Apple or Pear which has been gathered in the usual way, and lay it aside for a day or so, then carefully peel it, they will find it bruised, though not observable before. How does this happen? I answer, that it occurred during the operation of gathering, carelessly laying them in cane baskets, and in carrying them to the fruit-room; they are also hurt in moving them from one shelf to another. It is a general practice in large gardens, to intrust the gathering of fruits to persons who are regardless how they gather them; and this is a source of much mischief, as the fruit is often much injured by them.

It was a common practice, and is in some places now, to allow the fruit when ripe to fall of its own accord; and many plans have been adopted to prevent the fruit from injury by falling on the ground. Fruits allowed to remain on the trees till sufficiently ripe to fall of their own accord are much too ripe for preserving for any length of time. Some fruits, such as Peaches, Plums, &c. will not keep over a day or two; and the flavour of the fruit thus allowed to fall will be much deteriorated. There are certain criteria by which we may know with great nicety when fruit is in a proper state for gathering. Most fruits, such as Peaches, Pears, and Plums, part freely from the tree when ripe. Plums should be handled in the most careful manner, otherwise the bloom will be rubbed off them. When this is the case, a little fine flour should be carefully dusted over them, but with the greatest delicacy. Apricots should be gathered when the side next the sun feels soft, which may be ascertained by a gentle pressure with the finger. This fruit adheres firmly to the trees, and would, if not gathered, remain until it was over-ripe, and had become mealy. Peaches, Nectarines, Apples, and Pears fall of their own accord when fully ripe; but they should never be allowed to do so, for reasons before stated. The best plan is to gather all fruits, with the exception of stone-fruit, some time previous to their arriving at maturity, to place them in a warm room to accelerate their ripening, if they are required for immediate use. A good criterion with Apples and Pears is to cut up a fruit of average ripeness, and if the seeds have acquired a brown or black colour, they are in a fit state for gathering; but if they remain white, the fruit is not ripe, and should remain some time longer on the trees, even supposing a slight frost should intervene. Some sorts of Pears and Apples which have had a slight touch of frost are not injured by it; on the contrary, they will be found to have acquired a finer flavour. If severe frost should set in before the late sorts of Apples and Pears on the walls (which in some cold and unfavourable climates will be the case) have arrived at proper maturity for gathering, they should be covered by suspending canvas or bunting in front of them. Having procured the proper materials, and cut or sewed them into convenient lengths, they should then be fastened on the top of the walls by means of hooks and eyes of sufficient strength, and to pegs driven into the ground, at 2 or 3 feet from the wall; this covering should always be taken off during the middle of the day, and replaced in the evening; by this means they can be allowed to remain on the trees much longer, free from frost. If Apples have been pitted in the manner previously recommended, and if very severe frost should occur, the pit should on no account be opened if there is the least suspicion that the frost has reached them; if it is opened air will enter, and the consequence will be the entire loss of the fruit. When the frost has disappeared the pit may be opened with safety.

Cherries.—This fruit should be gathered when quite ripe. I, however, would recommend a portion of them to be gathered before being quite ripe, and if required for immediate use, they should be suspended over a hot-house flue in a basket, in order to accelerate their ripening. The remainder may be kept in air-tight tin cases, of a broad and flat form, packed in a little fine dry charcoal, Beech-flowers, or bran, until they are required for use.

Strawberries and Raspberries.—For these fruits, as far as I am aware, there has been no means adopted for their preservation for any length of time. I would recommend that the fruit which has begun to change colour (which some will do before others) should be gathered, and placed in a hot-house to accelerate the ripening; this will afford a succession. Fruits gathered in this manner and surrounded with silk-paper, and then packed in tin cases, thoroughly air-tight, with a little charcoal sprinkled amongst them, will be found to keep for some time; the later sorts of these fruits should only be preserved. The flavour of these and other fruits of this nature, which have been preserved in this manner, will not be so fine as those that are allowed to remain on the plants and ripened by the sun. However, fruits preserved in this way will be found useful for dessert, when those in the open air are finished.

Walnuts, Chesnuts, Filberts, &c., should not be gathered until they are quite ripe, and fall of their own accord from the trees. It will often happen, however, in late seasons, that the winter will be far advanced, especially before Chesnuts drop, therefore they should be gathered by means of ladders; but on no account should the trees be beaten with sticks, which is a very common practice, but cannot be too severely condemned. After they are gathered they should be divested of their outer shells, and gently dried after which they may be packed in boxes or casks, in fine dry sand or charcoal, in alternate layers, and placed in a dry cellar; the casks or boxes should be elevated on bricks, to prevent rats and mice from destroying them, which will be the case if they once gain admittance.

Packing for Carriage.—This is also an important point to be attended to, especially when over-ripe fruits have to be sent to any distance. In this, as in preserving and gathering, different methods have been adopted, and a great many of them without success. Baskets, for packing fruits, should on no account be used if it can be avoided. I would recommend two boxes, to be of different sizes, with false bottoms, and secured with a lock and two keys,—the one to be kept by the person who packs the fruit, and the other by the person who unpacks it. Boxes made of inch-deal have been recommended by some; these will answer the purpose equally well, if they have been made thoroughly air and water-tight. In packing fruits of all descriptions, the heaviest should always be laid in the bottom, and the more delicate on the top, each fruit being previously surrounded with clean linen or fine paper, and packed amongst bran, Beech or Hazel-flowers; fine-powdered charcoal will answer equally well, if it has been thoroughly dried previous to being used. Whatever material has been made use of for packing, when the fruit is taken out it should be properly cleaned, and laid in some cool cellar until required for use, first taking all bruised ones out and throwing them away; for, if they are left, they will impart a musty flavour to the others. For packing Grapes, I would recommend bran thoroughly dried, first putting in a layer of bran, then Grapes, shaking a little amongst the berries, which will fill up any spaces between them, and likewise prevent them from bruising each other; when unpacked, the bran will fall out from amongst them, and if any remain, it should be removed with a small painter's brush; the berries should then be treated as before directed, when they will be ready for the table.

The smaller fruits, such as Gooseberries, Currants, &c., should be packed in flat tin cases, and on no account should a large quantity be put into the case; if this is done, they will not be fit for use at their journey's end. All these small fruits should be packed in bran, which can be easily removed when they are unpacked; this will prevent them from bruising one another. When unpacked, they should then be laid in some cool apartment until they are required for use.—*John McIntosh.*

ROSE GARDEN.—No. XIV.

(*Continued from page 444.*)

Pushing Eye.—Sometimes a jet from an eye will start before the winter, and grow an inch or more; and this (if not killed by severe weather—a matter to be dreaded with a small and delicate shoot), will show a tendency to burst into leaf with the first intimation of spring. This is not desirable, as it would form one straight leader; and yet, from the little rings around it appearing so undefined, and no buds being clearly perceptible, the only chance of life appears in the summit. This, however, is not the case; and in order to delay it, and cause the sap to form buds on either side, the little shoot may be shortened to three or four rings, and left about an inch long; buds will then form on each side of its base, as well as from the rings, and instead of a single stronger leader, the tree will form a little head at once. This mode ought to be adopted also (when wood only is required) with the buds of the previous seasons' insertion, by nipping off the point of the shoot when three or four eyes have been formed; in this case the plant has not advanced enough to suffer the evil of a check, but rather a restraint, which being only just sufficient to increase the impatience of the plant to start into action, does not diminish the quantity of wood to be formed, but by multiplying the shoots, keeps it nearer home and forms a better head, yielding more buds to work from, and sooner than if left to run up, and for this reason less inclined to flower; this mode of treatment presupposes the plant to be both healthy and in good ground.

Guards against Wind.—The inserted buds, when vegetating, have, as has been before observed, no immediate junction with the stock; to prevent, therefore, their being knocked out by the wind, it is necessary to tie a small, but not flexible twig, as thick as the finger, to the stem of the tree, leaving a foot sticking out above; and when the jets are a few inches long, to tie them with a piece of bast to this guard to defend them from injury.

It sometimes happens, on looking at the buds which have taken and sprung several inches, that a want of vigour may be observed in some particular shoot, which droops as if about to die off. On examining this, it will be found that just at that place where the ripening had commenced, a slug has been at work, and eaten half-way through the shoot; whether it is that this operation is performed by the animal for the purpose of destroying the end, and eating it when dead, or merely to devour that small portion to which it has applied itself, does not appear, though, from the habits of the animal, the former is not improbable. However this be, slugs seldom sever the shoot the first time they attack it, but always return and finish what they have once begun. If the shoot were left to itself, the slug, or the next gust of wind, would destroy it. To avoid this, a small stick may be laid alongside the shoot, and both bound round and round gently with bast (covering the shoot close) to the top, the leaves only being left out, thus rendering it impervious to the attack of the animal, for at least two or three inches. A dead cabbage or other leaf may be placed at the bottom of the tree, and, in all probability, the enemy will be found under it in the morning; while by the precaution taken, the shoot will be protected from further injury, unless a fresh attack be commenced beyond the ligature.

Home Correspondence.

The Chiswick Exhibition and the Judges.—A communication in the last Number of the *Chronicle*, signed "One of the Judges (not of Heaths)," demands more notice than has been bestowed upon it. Although your correspondent, in his evident ignorance of the rules for the guidance of the judges, which year after year have been published by the Society, and also in the *animus* which pervades his communication, appears more in the character of a disappointed exhibitor, than of "One of the Judges," I will suppose him to be what he terms himself; and, granting this, I would ask, Whether the instance he so pointedly alludes to, and so strongly condemns, is the only one that ever came under his notice

during his extensive judicial experience? If not, from what motive has this particular case been selected from all others as the groundwork of his animadversions? It surely cannot be possible that a judge who professes so much liberality, would thus wantonly accuse his fellows of "exceeding their duty, overstrained discretion," &c., at the instigation of any disappointed exhibitor. For the sake of his consistency, I hope that this very just judge was not one of the fruit censors, because they acted on precisely the same principle that governed me and my colleagues; they withheld the principal prize from the Grapes exhibited by market-gardeners, because in their opinion the Grapes did not deserve the principal prize; they likewise gave a Silver Banksian Medal only to the second best Grapes in the same class, thus lowering the best production one degree, and the second best production three degrees in the scale of prizes. Of course your very censorious correspondent could not have been aware of this, or he would not have blamed us exclusively for merely doing the same. The matter has been brought so prominently forward, that I feel bound, in justice to myself and colleagues, to state the grounds upon which our decision was formed. There were two collections of six Heaths exhibited, one belonging to a nurseryman and the other to a private gentleman; consequently, as they stood in different classes, and did not compete one against the other, each would have been entitled to a Silver Gilt Medal had the plants been good enough to deserve it. The judges, however, considered that they were not, because, although there were some very good plants in both collections, they were not all good; and it was our opinion, and still is mine, that there ought to be six good Heaths shown to deserve a reward of 4*l*. In the nurseryman's collection all the plants were in good health, but two, if not three of them were much too young and small to justify their admission into a collection of six. The best grown plant, because the most difficult to grow well, in the other collection, was splendens; the other five (if I remember correctly, but certainly four) were critically compared with plants of the same kinds which formed part of a collection of twenty in the same tent, and in every instance to the disadvantage of those belonging to the smaller collection; we considered, in fact, that three separate collections of six plants might have been selected from the aforesaid collections of twenty, good enough to beat the two small collections now in question. Our decision, therefore, was not governed by "ideal notions of perfection," but by critical examination and careful comparison; and however loudly interested or inconsiderate persons may clamour against it, I feel confident that no conscientious man, who is in the habit of seeing good Heaths, would have decided differently. The office of censor at horticultural Exhibitions is by no means an enviable one, for, however anxious a man may be to do right, there are always some who, from interest, ignorance, or pique, are ready to repudiate his judgment, or impugn his equity. In the present case there must have been a stronger motive than ordinary to induce a person, who acknowledges that he has himself been persecuted by similar complaints, to come forward voluntarily and make a charge which I have shown to be wholly unfounded. Before leaving this subject, I wish to add my testimony to one part of the statement you made in reply to "One of the Judges." I have myself been a judge at the Society's Exhibitions for several years, and in no one instance have I ever known an officer of the Society attempt to lower the prizes which the judges had awarded; the whole responsibility of the awards consequently rests upon that body, and I, as one of them, am ready at all times to take my share of it; you are therefore at liberty to append my name to this communication if you think proper.—*One of the Judges of Heaths.*

What is a Flamed Tulip?—I am induced to ask this question in consequence of what occurred at the York Tulip Meeting. In the York Tulip schedule flamed varieties were mentioned, and sums of money attached to them as prizes, and being a judge upon that occasion, I very naturally refused to judge as flamed flowers those which the committee had selected as such, in consequence of their not having had a beam up the centre. An umpire was called in to decide the dispute, and the decision was given against me for this reason, viz.—because the flowers had the mother or breeder colour in them. In answer to what is a flamed Tulip? I will quote the opinion of Mr. Groom, given in the "Florist's Journal" for July, 1840. In page 57, line 15th from the top, after describing a feathered Tulip, he proceeds thus:—"Next to this comes the flamed flower, which should have, besides the feather, a rich beam up the rib of each of the petals, branching off on either side, and the points meeting the feather; at the same time preserving a sufficiency of the ground-colour between the flaming, to display it to the greatest advantage." In this description of a flamed Tulip I perfectly agree: for what constitutes a flamed Tulip except the beam?—and the cause of the beam is this:—The Tulip in breaking from the breeder leaves a portion of the mother or breeder colour which runs up the centre of the petal, and then strikes off with the real colour to the feathering; but why this is so is a mystery which we cannot unravel. It is so, however, and we can only surmise. To say it is an imperfect break would not do, as the majority of the finest Tulips are what are termed flamed ones; and if on that account they are disqualified, there will only remain a few of what are termed first-rate varieties. What is Salvator Rosa?—a flamed variety. Would you disqualify one of the finest Tulips in cultivation on account of the beam; or the mother colour, whichever you may be pleased to term it? What are Pandora, Thalia, Reine de Sheba *alias* Mentor, Ponceau très blanc *alias* Madame Catalina, Aglaia, Bijou des Amateurs, Bacchus, Cerise à belle Forme, Donzelli, Marcellus, Iago, Holmes's King, Polyphemus, Camarine, &c.? Further—What says the Editor of the "Florist's and Amateur's Annual?" In his properties of the Tulip he divides them into six parts, and in his 6th section of the properties, he comes to the marking, and he thus writes:—"The marking of the petals regular and uniform, whether it be a broad or narrow feather round the edges of the petals which are exposed, or a flame up the centre, and branching off, and though very rarely uniform in this respect, the nearer approach the better. So much in regard to the properties for showing." But the writer must have forgot this published opinion, when so lately as the 29th of June he says—"No flower can be good for show if it has the breeder colour in it;" and on the 6th July he says—"A Tulip should not have any of the breeder colour in it." I can only account for this on the following grounds, namely:—The question has not been fairly stated to him. If it was a feathered variety, and had breeder colour in it, I agree with him that it ought to disqualify a pan, providing the other pan or pans have not the same glaring fault. There has never been but one instance, I believe, of the beam and feathering being of the same colour; but I must admit that the nearer the approach to the colour of the feathering so much the better. A Tulip in the north, if the beam is very pale, is not considered of so much value as one very dark. Aglaia, although a pretty variety, is very defective in the beam. In some instances it is uncommonly pale, and at other times the colour is tolerable. The same may be said of many others. If the taste of the York florists is correct, then it will be a mere mockery to offer prizes for flamed Tulips, if those only which are what are termed, and correctly so, neither feathered nor flamed, are to be classed as such. I have a work before me upwards of 100 years old, written by the celebrated Dutch florist Nicholas Van Kampen, and the properties he lays down are in accordance with what has been previously expressed. The authorities quoted, however, are sufficient to satisfy any Tulip-grower, they being, as they are, the opinions of the best florists in the country; and I trust that the properties already alluded to will for the future form the standard of a flamed Tulip, being persuaded that they are strictly in accordance with the opinions of all England, excepting within a circuit of about 30 or 40 miles round York. I must, in justice to Leeds, Wakefield, Halifax, and their neighbourhood, say that their opinion is in accordance with the general one, and all flamed flowers are judged according to Mr. Groom's standard.—*John Slater, Cheetham Hill, near Manchester.*

Raspberries.—In the "Theory of Horticulture," the practice of training trees upon a horizontal plane is condemned, and reasons for objecting to the plan are given. It is there stated that "such a mode of training exposes a tree as much as possible to the effect of radiation." A proof of this has occurred with me this season. A part of my Raspberry plants is tied to upright stakes, another portion is arched. We had a severe frost here on the morning of the 20th of May, which did considerable injury, and Raspberries came in for a share of the suffering. Those plants, however, that are trained in an upright manner, appear to have suffered less than those that are arched. They are growing in the same soil and situation; on some of the arched plants scarcely any fruit have set, and I can give no other reason for the failure than that they have had a greater surface exposed to the frost than the others.—*Peter Mackenzie.*

Plantations.—Much has been said and written on this subject; and whilst the advocates of the several methods recommended for the improvements of our plantations have occasionally differed, so far as to afford room for controversy, it may nevertheless be said, that such difference was not so much in principle, as in degree; consequently the discussions which from time to time have arisen, do not so much refer to the merits or demerits of any particular system, as to the extent to which an acknowledged system ought to be carried. Of the advantages resulting from the operations of pruning and thinning, no one in the smallest degree acquainted with the management of young plantations entertains a doubt; but as to the time and manner in which their operations ought to be performed, and the extent to which they ought to be prosecuted, there are still many waverers; and if those who, through the medium of the Press, have favoured us with their views and notions on these important points, differed in degree, so also have their followers; and it may be said that the hand of the wood-forester of the present day, so far as regards pruning and thinning, is heavy or light, just in proportion to the extent of his faith in the efficacy of the same. The writer has been led into these remarks from what occurred to him on a late visit to the woods at Nerquis, in Flintshire, belonging to Dr. Thackeray, of Chester, (a gentleman favourably known as a planter of forest-trees.) The plantations here alluded to extend to about 450 acres. They were planted by Dr. Thackeray, in 1814, and have been pruned every year, and throughout the whole year round from that period to the present time, (some of the trees several times in one year,) the effect of which has been, that whilst there is perhaps not another plantation in the kingdom of similar extent, where the proper system of early pruning and thinning has been prosecuted with the same degree of nicety, there is not to be met with, in any other part of the country, a plantation more uniformly thriving, or that bids fairer to become in time a source of wealth to the proprietor, an ornament to the country, and a luxury to all who possess any taste for magnificent forest-trees. In these plantations there is no exemption from the pruning process,—every tree in the wood having been reared under the influence of the knife and chisel. The Oak, the Ash, and Elm, together with the Larch, the Scotch Fir, the Spruce, and other varieties of the Pine tribe, are made to share the same fate; and in every case the success has been complete. There are many who maintain that pruning of a kind so rigorous as that here instanced, is calculated to weaken and produce sickness in the stem; and there are others who, while they approve of, and extensively practise pruning of all descriptions of hard-wood, object to the process being extended to Larch and Fir, on the ground that if it would not be detrimental, it would at least be an unnecessary expense. Without meeting these objections by a train of arguments, which might be satisfactorily done, suffice it to say, that the evidences of results prove the contrary; and were those who still adhere to the objections noticed, only to visit the plantations forming the subject of these remarks, there would be no resisting the evidence which they furnish; there they would not merely have an opportunity of witnessing the beneficial effects resulting from a complete system of training, but they would also have an opportunity of witnessing the injurious effects resulting from an opposite course of management: for in the plantations, not only in that, but in the adjoining counties—particularly in Delamere Forest, belonging to the Crown, planted at the same time, and possessing greater natural advantages—the system of "Let nature work," appears to have met with but small interruption. In the one case we have clean vigorous stems, standing at proper distances, and uniformly handsome; whereas in the other we have only a thicket of dwarfish bushes grown wild from neglect, and having more the appearance of puny shrubs than forest trees; and, but for abundant evidence to the contrary, the failure in this would, no doubt, as in similar cases, be attributed to an unfavourable climate, sterility of soil, or some such cause; in short, to everything but the real cause—neglect of culture. In highly favoured situations trees will push up almost in defiance of neglect: it is not so, however, in regard to all situations; and those who would successfully grow timber on poor mountain-land, must have recourse to the arts devised by human skill, otherwise it would be in vain to hope for favourable results. As a further proof of the good effects of early and regular pruning, there are some trees growing at Craiglelo, near Ruthin, in Denbighshire, planted also by Dr. Thackeray, about 38 years ago, for W. Jones, Esq; several of these contain upwards of 35 cubic feet of timber, and they were regularly pruned for 14 years after they were planted. The situation of the plantations noticed above is not by any means favourable; that at Nerquis stands at least 800 feet above the level of the sea, has a northern exposure, and is as poor mountain-land as is almost anywhere to be met with. It was purchased by Dr. Thackeray expressly for the purpose of planting, for a mere trifle; yet, although planted only in 1814, many of the Larches contain from 8 to 9 cubic feet of timber, and there are Oak saplings that measure from 25 to 30 feet in length, and that girt from 30 to 32 inches at two feet from the ground; from these, and other similar instances, we may conclude that very great improvements might be effected in planting, by adopting a system of treatment of the kind practised, in the cases to which I have directed attention. In most parts of North Britain the art of pruning, accompanied with proper thinning, is well understood and generally practised; but there are other parts of the kingdom, equally adapted for planting, of which so much cannot be said; indeed, in the principality generally the woods are neglected, and there is reason to fear that the great indifference on this subject so prevalent in that part of the country is neither more nor less than the offspring of ignorance.—*A Scotchman, Wales.*

Thrips.—These are more easily destroyed in Cucumber and Melon-frames than in a greenhouse or a conservatory. Let a common Cucumber-frame, say a two-light box, be provided with 12 or 16 common garden flower-pot pans large enough to hold a quart or three pints of water; fill them and place them between the plants, or wherever it is convenient; procure as many pieces of fresh unslacked lime as you have pans, and pour on each piece a few drops of spirit of hartshorn; then place the lime in the pans of water, taking care to keep the part on which the hartshorn was dropped a little above the surface of the water; afterwards, shut down the lights close, and let them remain so for two hours. If the sun shines so much the better, provided you have not too strong a bottom-heat. By this means a gas is generated which is destructive to animal life, and at the same time beneficial to plants. In the case of Cucumber-frames, the pans of water may remain until the water evaporates, and the Cucumbers will even be all the better if the pans are again filled up.—*W. P., Shirley Nursery.*

Potatoes.—Pulling off the blossom has, to my knowledge, been practised most beneficially for more than 20 years. It stands to reason that, if the plants exhaust themselves in forming seed-pods, the produce of the roots must be diminished. Let any sceptic select four rows of Potato-plants, planted at the same time and of the same sort, and from rows 1 and 3 pluck off every blossom as it appears, and upon the plants in rows 2 and 4 permit every blossom to come to maturity, and when the roots are ripe let him weigh the produce of the rows 1 and 3 against the produce of the rows 2 and 4, and communicate the result honestly to the *Chronicle*; and I shall be surprised if he persists in permitting his Potatoes to expand their bloom.—*A West Countryman.*

Ash-leaved Kidney Potato.—The origin of this Potato is imperfectly known; it was raised from seed of the Mouse Kidney near 40 years since, at Retford, in Nottinghamshire, by John Holberry, a shoemaker of that town. I seeded it in 1826, and raised several varieties of Kidney from it, but none of them was so good as the original.—*F. X. O.*

Whitney's Composition.—Mr. Whitney, I see, upholds his statement that a quart will coat twice 7.5 square feet. I can only say I applied his liquid with my own hand, and so carefully, that the process of scraping "next day with a card" was superfluous—there was nothing to scrape. I used it too, as hot as, without a varnisher's stoved-room, could be done. I had the greatest difficulty in eking out a second coating for 60 feet and a few inches of the glazed calico. It is still quite possible that, working in a large way, with large brushes, a large quantity of the liquid retaining naturally its heat a longer time, and with an apartment regulated for the especial purpose, Mr. Whitney may effect what he says. So respectable a man, as I believe him to be, cannot have intended to deceive the public; but I am strongly of opinion, nevertheless, that his statement will disappoint them as to the above point.—*W.*——Another correspondent writes thus:—I have tried Whitney's Composition for a covering for a turf-pit. The material used was calico at 4*d.* per yard. I find it answer the purpose admirably; but it comes greatly deficient in covering the extent of cloth specified in the printed directions. The pit I had made for the purpose of protecting half-hardy plants; after they were turned into the beds, I introduced Heaths and various other plants, all of which thrive under it; while those exposed to the action of the scorching rays of this uncongenial season are of a sickly hue. I do not consider bookmuslin a suitable article for the purpose; I think the stronger the calico is, the better. One of my workmen unluckily put his foot through one of the lights; in that case the glasier could be of no service to us: we had recourse to needle and thread.—*James Melville, Gardener, Murton Rectory.* [We have an endless tissue of complaints of the same kind, and our own experience confirms our correspondents' statements. It is, therefore, not worth dwelling further on the subject.]

Peas.—With regard to the Early Kent Pea, in addition to what an "Arbroath Gardener" says, I would state that I sowed it and the Early Warwick on the 6th of February, on the same border, and under exactly the same circumstances. I could have gathered the Kents on the last day in May, but there being a Horticultural Exhibition in this neighbourhood on the 5th of June, they were reserved for that occasion, when although there were seven exhibitors of Peas, my Early Kents won the first prize; they were about 11 or 12 days before the Warwicks.—*J. M., Cheshire.*

Foreign Correspondence.

Société Royale D'Horticulture de Paris. — This Society has again shown its incapacity of getting up anything like a fine floral Exhibition, although it can and has during the past week drawn together 2000 or 3000 plants (such as are daily seen in the markets) which may delight or amuse the idlers of Paris; but to suppose that any possible benefit can accrue to Horticulture as these Shows are now conducted, is a complete mockery; preposterous regulations will most assuredly render abortive the patronage, influence, and money lavished upon this Society. What would be thought in England of a management which required conformity to rules like these?—"1st. All plants to be in the room before 12 o'clock on Monday, and placed in lots upon the ground ready for the inspection of the judges. 2nd. The judges will examine the lots and award prizes on Tuesday, between 10 and 4 o'clock, after which exhibitors must remove their plants from the ground and arrange them upon stages. 3d. The public will be admitted from 10 to 6 on Wednesday, Thursday, Friday, Saturday, and Sunday, during which time each exhibitor must pay attention to his own plants." Would it have a single exhibitor? I think not, let the prizes be ever so tempting; yet such is the system adopted here. Is it, then, marvellous that France, with all its advantages of locality and climate, should be fifty years behind England, Belgium, or Germany, either in new plants or successful culture. Great exertions had been made to render this *fête* attractive, for, independent of the prizes offered by the Society, were four Gold Medals, one from the Duchesse d'Orleans for the best collection of plants; another from the Princesse Adelaide for a new rose; a third from some lady patronesses for the finest plants in flower; and a fourth for the finest forced fruits; beside two large Silver Medals from the city of Paris and the Luxembourg for fruit and vegetables; but even here the same mismanagement was apparent, for these prizes were only publicly made known a few days before the Show. They certainly do these things better in England. The weather was splendid during the whole week, but too hot for the Roses, which cut but a very sorry figure even by Wednesday, when the public was admitted. The company was not so numerous as usual; perhaps the superior attractions of the Champs Elysées might have caused this; nevertheless, several thousand persons visited the Orangerie of the Luxembourg, which was free to all the world. As to fine specimen plants, scarcely one was to be found. Messrs. Cels, as usual, sent a large collection of Cacti and miscellaneous plants, among which was a good Cattleya Mossiæ, Oncidium papilio, Mamillaria dolichocentra, serieata, and Melocactus cephalomorphus; but the very small number of plants in flower was a great detraction from its beauty. The Gold Medal of the Duchesse d'Orleans was awarded to it. M. Morel showed Brassia macrostachya, Lælia cinnabarina, Gongora maculata, and Oncidium pulvinatum. M. L'Homme gained the Society's first prize for hothouse plants, among which were Latania sinensis, Columnea Lindenii, Anthurium Hookeri, Hotæa japonica, Cendollea cuneiformis, Sabal Adansoni, Adiantum tenerum, Cheilanthes lendigera, together with a pretty collection of indigenous Orchises. The Roses in pots were very poor after those I have just seen exhibited by Messrs. Lane and Beck in England. The varieties were good, but the plants badly grown: in the same collection might be seen standards 5 feet high, and others 12 inches, which showed a miserable want of taste. The collection of M. Margottin gained the first prize—some flowers of Comte de Paris, Triomphe de Luxembourg, Smithii Gigantesque, Bougere, Maugais, Suchet, Reine des Iles Bourbon, Aubernon, and La Reine, were very large. M. René was second, and also showed good flowers of Gombault, Lady Warrender, Eliza Sauvage, Lamarque, Devoniensis, Comte de Paris, Paul Joseph, and Madlle. Hardy; but the weather was evidently too hot to see them to advantage. Seedling Roses (cut) were numerous, and the Gold Medal from the Princesse Adelaide was gained by M. Hardy for a large flower very much like the old yellow China, which was named Madame Adelaide; he had also another pretty seedling, named Princesse de Joinville, in the shape and way of Aimé Vibert, with a sulphur tint. In his general collection were some fine blooms of Belle Portugaise, a bright-red hybrid, Dupuy, black, Bougere, and Vandael. M. Laffay gained the Society's seedling Rose prize; he had several hybrid perpetuals,—the Comtesse du Chatel is good but not equal to La Reine, which he sent out last autumn. M. Verdier had a collection of Cût Roses, to which was awarded the Society's Medal; it numbered nearly 500 varieties of Provins, Hybrids, Perpetuelles, Tea, Bourbons, &c. The Geraniums were numerous—certainly not less than one thousand plants were exhibited; but as quantity seemed to be thought more of by the judges than quality, I need only say that the greater part were such as are sold in the markets at 10 sous each. MM. Chauvière and Souchet had, however, prizes for them. Fuchsias were not numerous. M. Lemon was awarded a prize for some pretty Iris Germanica, and M. Dufay for grafted Dahlias, which form nice dwarf bushy plants in pots, and flower early. M. Bachoux gained the first prize for a general collection of hot and greenhouse plants, among which were the curious Ceropegia stapeliæformis and Mesembryanthemum obconellum, and a good Mammillaria nivea. M. Rythogel was awarded the prize for new plants, hardly one of which was in bloom. Billbergia zebrina was in this and other collections. M. Modeste was as usual without a rival in Chinese Peonies, and showed fine blooms of Triumphans, Reine Hortense, Victoire Modeste, Comte de Paris, and Perfection. M. Malingre was awarded the seedling prize for a collection of Alstrœmerias, which, however, seemed very like some cultivated by Mr. Gaines ten years since. The grand attraction was the fruit exhibited by M. Bergmann, gardener to Baron Rothschild, to whom was awarded the Lady Patronesses' Gold Medal, for six Providence and Moscow Queen's Pines, which were magnificent; in fact, such as either Mr. Spencer or Mr. Barnes might have been proud of showing. M. Grison had also a Gold Medal for a basket of Fruit—Peaches, Apricots, Grapes, Figs, Plums, Cherries, and Currants; and also the Silver Medal for some fine Cauliflowers Artichokes, and other vegetables. M. Puquet showed 120 Apples—Calville Blanche, Canada Pippin, Reinette franche, and St. Germain Pears, preserved after a new method, which looked as plump and fresh as they usually do at Christmas; for these a Silver Medal was also given. M. Duluc gained the Luxembourg Silver Medal for Melons, Cauliflowers, and Cabbages, which, however, were not equal to those of M. Grison.

Societies.

BOTANICAL SOCIETY OF LONDON.

June 7.—J. Reynolds, Esq., Treasurer, in the chair. Specimens of Œnanthe peucedanifolia and Œnanthe pimpinelloides were exhibited, accompanied by notices of their distinctive characters and habitats, by E. Lees, Esq. Much uncertainty and confusion having prevailed among British authors and distributors in regard to the distinctions between these species, the views of Mr. L., founded on good opportunities for observation, are deserving of particular attention. The following condensed abstract will explain the conclusions formed by this botanist. 1st. Œ. peucedanifolia always grows in wet places, and is found both by salt and fresh water, while Œ. pimpinelloides is found in dry ground only. 2d. The characters derived from the form of the radical leaves, and the presence or absence of an involucrum, will not prove sufficient to prevent confusion, but the rounded tubercles upon the roots of Œ. pimpinelloides will readily distinguish that species from Œ. peucedanifolia, in which the tubercles are elongate and sessile. 3d. There is some difference in the fruit of the two species, though the materials in the possession of Mr. L. are not sufficient to state this with precision and certainty. Mr. L. thus attaches the first importance to the form of the root, as a distinctive character; and this circumstance should instruct collectors to be mindful of the value of the root. Specimens collected by Mr. L. afforded the principal reason for retaining Œ. pimpinelloides as a British species, in the London Catalogue, in preference to the adoption of Mr. Babington's change to Œ. Lachenalii; and one of the same specimens communicated to Mr. Ball induced that excellent botanist to admit Œ. pimpinelloides, as well as Œ. Lachenalii, among the indigenous species. Three species, not two only, should therefore now be looked for, and the confusion and uncertainty may thus be removed. Most of the specimens hitherto sent to the Society have proved quite useless, through the absence of roots and fruit; but it is earnestly requested by the Council that contributors will collect specimens with roots and fruit, from as many localities as possible. Some highly-interesting examples of the Irish Saxifrages, belonging to Haworth's genus Robertsonia were exhibited from Mr. Andrews, who had obligingly sent living plants as well as dried specimens. Two of the specimens were sent in record of the fact, lately doubted or denied by the accurate Mr. C. C. Babington, that the Pyrenean forms of S. umbrosa, and S. Geum (with crenate leaves), are certainly native in Ireland; the specimen of S. Geum, indeed, being considered "even more obtusely crenate than Mr. Babington's figure (No. 8), from the Pyrenean plant." These specimens were collected "this year, from the mountains to the south of Brandon mountain, county of Kerry." S. hirsuta is considered by Mr. Andrews to be a hybrid form between S. Geum and S. umbrosa, "as many of the varieties present characters leaning either more or less to the one species or the other." S. elegans is deemed by Mr. A. to be simply a variety of S. umbrosa; and after a careful examination of the forms of S. hypnoides, he is now "satisfied that S. affinis, incurvifolia, hirta and palmata, are all mere varieties, or indeed, barely deserving the name of varieties." Read, "A Synoptical View of the British Fruticose Rubi, arranged in Groups, with explanatory Remarks," (Part 3,) by Edwin Lees, Esq., F.L.S. The paper was accompanied by drawings and specimens.

ENTOMOLOGICAL SOCIETY.

July 1.—George Newport, Esq., in the Chair. Mr. Marshall stated that he had taken home the specimens of Coccus upon the Lime, produced at the last meeting by Mr. Thrupps, and found that they had produced hymenopterous insects. — Mr. Westwood stated that some of the Ichneumonidæ deposited their ova in the Cocci, and this was undoubtedly the case in the present instance. A want of attention to the habits of the Ichneumonidæ had led to the supposition that the male of the Coccus was a winged insect.—A collection of small Crustacea from New Zealand and Swan River, was presented by the Rev. F. Hope.—The committee appointed at the last meeting to inquire into the subject of the Coccus attacking the Orange groves of the Azores, had sent in their report to the Orange Company. They had not been able to propose any remedy which offered a prospect of immediately exterminating the pest. —Specimens of the Saropoda fuscata, which had been attacked by the Cælioxys conica, were exhibited by the President.—Captain Parry exhibited a box of insects from New Zealand, which contained, amongst other things, a remarkable species of wingless Grasshoppers, a species of Boletophagus, and a specimen of Sirex gigas. —Mr. Yonell exhibited specimens of the leaves of a Lime-tree, covered with little conical projections, produced by the deposition of the ova of a species of Aphis.—The Rev. F. Hope exhibited specimens of Goliathus Savagesii and G. Polyphemus.—Mr. Westwood exhibited also a drawing of the G. maximus, in the possession of Mr. Turner, of Manchester, which he believed was only a variety of G. Druriі.—Several drawings of insects were exhibited from Robert Templeton, Esq., of Ceylon, and a letter was read, in which that gentleman announced that he was rapidly proceeding with his work on the Zoology of Ceylon. He referred to the bites of Scorpions, and the Scolopendra generally, and expressed his conviction that they were not poisonous. This gave rise to some discussion, in which the President stated that these insects possessed a special glandular apparatus for secreting poison; and Mr. Hope and other Members related instances of inflammatory action following their bites.—The Rev. F. Hope read a paper on some species of Buprestidæ, from Australia. The paper contained a description of 37 species, but he possessed still many undescribed. He also exhibited drawings of fossil insects identical with living species, found in the tertiary deposits of Aix, in France. He had also received others from Senegallia, in Italy.—Mr. Westwood stated that in May he had seen a swarm of female wasps feeding on some leaves affected with honey-dew. They might have been easily destroyed, and with them their coming progeny. A discussion took place as to the advantage of killing wasps, as it was well known that they destroyed many species of flies which were equally destructive with themselves.—Mr. Westwood read a paper on some new hemipterous insects. One of these he called the Plataria Madagascariensis, as he had first seen a specimen from Madagascar in the Museum of the Jardin des Plantes at Paris; but he had since received a specimen from South Australia.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

The midsummer meeting of this Society was held in their garden at Inverleith, near Edinburgh, on the 28th ult. The grounds were in the highest state of beauty, and the company numerous. For the four finest specimens of Cape Heaths, the silver medal was voted to Mr. J. Reid, gr. to Professor Syme; the kinds being Erica Savilleana major, ventricosa pragnans, tricolor speciosa, and Woodhall ventricosa; 2, Mr. G. Binnie, gr. to Professor Dunbar, for E. splendens, ventricosa, pragnans, ventricosa stellata, and ventricosa tricolor; 3, Mr. G. Stirling, gr. to Lord Melville, for E. ventri-

cosa nana, tricolor, Savilpana major, and purpurea.—For the three finest and recently introduced varieties of Fuchsia, there were eight competitors. The silver medal was assigned to Mr. J. Downie, gr. to General Robertson, who produced F. Rogersiana, Eppaii, and magnifica, (besides several very large varieties sent for exhibition only); 2, Mr. R. Oswald, gr. at the Orphan Hospital, for varieties named Prince of Waterloo, Magnificent, and Fairy Queen; 3, Mr. J. Young, gr. to T. Oliver, Esq. for F. excelsa, racemiflora, and pulchella.—The show of Roses was on this occasion magnificent. For a general collection, consisting of sixty named sorts, the silver medal was voted to Messrs. Handasyde, nurserymen, Fisher-row. For the best twelve hybrid varieties of the China Rose, the silver medal was awarded to Mr. P. Thomson, gr. to J. J. H. Vere, Esq., for R. odorata, Devoniensis, tea-scented, Blairii, Camelliæflora, white China, Princess Augusta, Sir Walter Scott, Yellow China, Swan-neck, Crimson China, and Doctor Billiard; 2, Mr. A. Forrester, gr. to Capt. Falconar, for R. Blairii, Belzance, Beranger, Blanche, Mrs. Boyle, Indica major, Fabvier, Girliug, Paroquet, Devoniensis, Maria Stuart, and Magna rosea.—Comparatively few tender shrubby Exotics were sent for competition; but for one collection, consisting of Epacris grandiflora, Elichrysum proliferum, Erythrina laurifolia, and Leschenaultia biloba, a premium was awarded to Mr. Young. For an admirably grown specimen of Pimelea decussata rosea, another premium was voted to Mr. P. Crocket, gr. to Col. Ferguson.—Many beautiful tender shrubby exotics, for exhibition only, were sent by Mrs. Haig, Professor Dunbar, J. Henderson, Esq., and Mr. J. Macnaughton.—Some very beautiful tropical Orchidaceæ were produced in full flower; a premium was awarded to Mr. Stirling, for Oncidium Harrisonii and Maxillaria Harrisonii.—Beautiful specimens of Stanhopea grandiflora, Oncidium cupreum, and Acropera Loddigesii, from View Park, were sent, not for competition.—The competition in stage Pelargoniums was limited, and the prize was gained by Mr. Young, with varieties called Duchess of Sutherland, Enchantress, Mabel, Beauty, Caroline, and Rising Sun. But the specimens sent for exhibition only were never excelled either in number or splendour, the principal exhibitors being Messrs. Dickson and Co., Leith Walk; Dickson and Sons, Inverleith; and Carstairs, Kelly, and Co., Warriston.—For remarkably well-grown herbaceous perennial plants, two premiums were voted: the first, being the silver medal, to Mr. Young, gr. to Mrs. H. N. Ferguson, for a splendid specimen of Achimenes grandiflora; and the next, to Mr. Forrester, Cailourie, for Orchis foliosa.—For producing the four most curious or uncommon native British plants, in pots, a premium was awarded to Mr. Stirling, the plants being Aceras anthropophora, Eriophorum alpinum, Asplenium viride, and Sedum dasyphyllum. To the same another premium was adjudged, for two trays, one filled with exotic, and another with indigenous alpine and rock plants, several of them of great rarity and beauty.—An extra award was made to Mr. Gow, gr. to Count Flahault, Tullialan Castle, for a collection of Cut Flowers of more than 30 varieties of seedling Rhododendrons raised by himself. Among the remarkable plants exhibited was a magnificent specimen of Erica spuria from the Royal Botanic Garden, upwards of 8 feet high and 15 feet in circumference, the whole plant being completely clothed with rich blossoms; together with several other fine heaths of large growth.—Clerodendron Kæmpferi, in full flower, was sent by Messrs. Lawson and Sons. Echites atropurpurea, was from the Society's own collection. Nemophila discoidalis, was from the garden of the Orphan Hospital. Delphinium Menziesii, a Columbia river species, was sent by Mr. Guthrie, Dundee. A basket of the highly scented flowers of Mandevilla suaveolens was from Archerfield Garden, where the plant is grown in great perfection. Trays of very lovely Pansies were exhibited by Mr. Symington, Mr. Finlayson, Mr. Rutherfurd, and Mr. Murray. A luxuriant specimen of Heracleum giganteum, eight feet high, was sent by Dr. Neill, marked as having been grown on a very poor sandy bank, entirely without manure. Mr. Sang, of Kirkaldy, sent a dish of the ripe fruit of Rubus spectabilis, which was found not very palatable, and proved that this species is more adapted for ornament than utility.—Mr. Adamson, Balcarras, sent a Melon and a brace of Cucumbers.

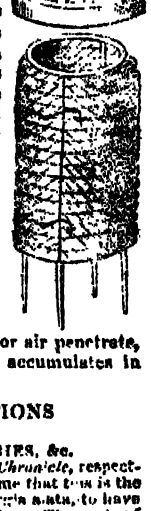
BOTANICAL SOCIETY OF EDINBURGH.

June 13.—This Society met at the Royal Botanic Gardens—Professor Graham, President, in the chair. After a delightful walk through the garden and planthouses, accompanied by the learned president, who pointed out many of the beautiful specimens which they contain, the meeting re-assembled in the classroom, when the following papers were read. 1. On four Genera of Desmidieæ, by Mr. J. Ralfs, Penzance. The genera are Cosmarium, Pediastrum, Xanthidium, and Scenedesmus, and the descriptions of them, which were accompanied by illustrative drawings, will shortly appear in the "Annals and Magazine of Natural History." 2. Continuation of Mr. James M'Nab's Journal of a Tour through part of the United States and the Canadas. In the previous part of this journal, Mr. M'Nab gave a brief outline of the principal botanical and horticultural features observed in the neighbourhood of New York. The part now read, embraced chiefly the appearance of the country around Albany, with an account of the more interesting plants seen during the journey thither. Among these, the most remarkable were several species of Lycopodium, with which the peaty soils on the road-sides around Albany were covered, consisting of complanatum, clavatum, and dendroides, the latter resembling at a distance young spruce Firs—being similarly shaped and of a lively green colour. In damp situations in the close forests, Adiantum pedatum and other ferns covered large tracts, while Pyrola elliptica and rotundifolia, with Chimaphila maculata and umbellata were in full flower along the drier parts. Satyrium herbiola, and Neottia tortilis were also observed—the latter growing chiefly in pairs. The principal plants noticed in the meadows or open grounds were Lilium Philadelphicum and Canadense, Mimulus ringens, Verbena hastata, and urticifolia with Asclepias obtusifolia and variegata. Proceeding towards Troy, on the banks of the Hudson, great quantities of Kalmia angustifolia, Cornus florida, Lupinus perennis, Andromedas, Vacciniums, &c., occurred. In an extensive forest, chiefly composed of small trees, and much entangled with Smilax or green Brier, through which the party proceeded with great difficulty, Cypripedium spectabile covered large patches, with Arum triphyllum, the latter in full flower. Mr. M'Nab concluded the present part of his journal with an account of some large trees of the hemlock spruce, Abies canadensis, being the first of this tree which the party had observed in natural situations;—the largest specimens were about 10 feet in circumference, and 80 feet in height.—The Honourable G. C. Cunningham, Mauritius, and F. S. Cordier, M.D., Paris, were elected foreign members; and A. Greenwood, Esq., Chelmsford, Essex, was elected a non-resident Fellow of the Society.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

Clitoria Fulgens. Bright flowered Clitoria (*Twining Evergreen.*). Leguminosæ. Diadelphia Decandria.—This is an elegant addition to the number of those plants usually called creepers. It was obtained by Messrs. Veitch and Sons, of Exeter, who exhibited a specimen at the Horticultural *fête* at the Chiswick Gardens in May, as a species of Centrosema, one of the division of the genus Clitoria. It was discovered by their collector, Mr. Lobb, growing on rocks,—over which the graceful slender branches spread in all the wild luxuriance of nature,—on the Organ Mountains of Brazil, in the autumn of 1840; and seeds were received from him, at the Exeter Nursery, in the spring of 1841. These were sown immediately, and produced plants which flowered for the first time, though rather scantily, last autumn. The abundance, however, in which the blossom buds have been developed during the present spring, justify us in considering it most likely to prove a very free-blooming plant. The long, slender, and slightly hairy stems, are well adorned with handsome foliage, having a smooth and bright-green upper surface, and the lower side of a paler hue, closely covered with numerous very short soft hairs. The slightly depressed position of the leaves has a pretty appearance, especially when the stems are trained spirally round a basket, as they then fall over each other in a neat and loosely tiled manner. From the axils of the leaves, the flowers are produced in a clustered head, supported on a stiff and wiry peduncle five or six inches long, elevating them sufficiently above the foliage to display, without interruption, the bright and glowing scarlet blossoms. It has, hitherto, been cultivated in a house intermediate betwixt the stove and greenhouse, but it will probably be found to succeed pretty well in the ordinary temperature of the greenhouse. It thrives well in a mixture of peat, loam, and sand, and when removed from a small pot to a large one, its natural situation among rocks would point out the propriety of intermingling with this compost a few pieces of porous, broken pot, or charcoal, to keep the soil open, and facilitate drainage. And, although it will need a reasonable abundance of water during the season of growth, it will be proper to limit the supply in winter, as moisture is then liable to injure it, especially with a low temperature. Seeds have not yet been produced in this country, but it strikes root with tolerable freedom, from cuttings.—*Paxton's Magazine of Botany.*

Garden Memoranda.



Bank Farm, near Kingston, the residence of Sir John Broughton, Bart.—We visited this charming place to see the collection of Pelargoniums, which are now at the best, and were highly gratified to find some of our old favourites keeping their places, in spite of the new varieties which have annually appeared. When we looked at them we could not but wonder why, when such beautiful flowers as Matilda, Nymph, Queen of the Fairers, Erectum, &c., can be purchased at less than 5s. each, such inferior sorts should be cultivated as are too often to be met with, even in collections where a better taste might reasonably be expected. We were never more struck with the superiority of nature over art, than in the present instance. Plants of vigorous and robust habit, grown in moderate-sized pots, had sent up fine heads of bloom, which they supported in graceful negligence, without any help, the mingled colours contrasting finely with the clear, dark-green foliage. Not a fly or the mark of one was to be seen; upon close inspection, however, a good deal of run colour might be observed — which is the fault of the extremely hot weather—but the plants being judiciously placed upon the stage this did not materially detract from the general effect. We must leave to a future day the contents of our note-book, and will conclude by remarking that the taste and liberality of the proprietor, being well seconded by the gardener, (Mr. Redding) were manifest in everything we observed. All the plants cultivated at Bank Farm are specimens of their kind; and whether they are beneath glass, or in the beds and borders, the general effect, on the closest examination, alike proved the wisdom of doing that well which is done.

Miscellaneous.

New Horticultural Expedition.—A new voyage in search of plants is on the point of being undertaken by Mr. Lowe, jun., of the Clapton Nursery, who proceeds to the Straits of Malacca, with the intention of visiting Borneo and Java, and if possible, the coast of Siam, Celebes, and New Guinea. The spirit of enterprise which leads to so arduous an undertaking cannot fail to bring an ample reward; and we have no doubt that the name of Mr. Lowe, the younger, will soon rank among the foremost of those bold spirits to whose dangers and sacrifices the unparalleled magnificence of our gardens is chiefly owing.

New English Dye.—Dr. Robert Thomson has lately published an account of the dyeing qualities of the common yellow pale Lichen (Parmelia parietina) which he finds to contain a peculiar colouring matter, called Parietin, of a bright yellow. This is heightened by a drop of nitric, muriatic, or sulphuric acid, while minute quantities of ammonia, or other alkalies, change it to a rich red inclining to purple.

A Shelter for Young Plants.—This shelter is more especially destined to be placed near houses in places where other such contrivances would produce a disagreeable effect. It is composed of two moveable semi-cylinders, constructed in the way of straw hives. To these semi-cylinders are fixed solid feet of wood, for the purpose of being driven into the ground. If it is only necessary to shelter one plant from east or north-east winds, one semi-cylinder is sufficient; but if it is a plant which you are forced to protect, is delicate, and requires a more complete protection, you inclose it between the 2 semi-cylinders fixed one to the other by means of hooks represented in the drawing. A lid of the same construction, furnished at its edge with a circle in wood-work, is fitted, when necessary, upon the cylinder, and thus perhaps offers a more effectual shelter against the severity of cold winds and excessive heat than any other. These sorts of shades are light to move, very solid, and very warm; for, letting but little of the exterior air penetrate, they preserve very well the heat which accumulates in the interior.—*Revue Horticole.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

The answer given to Mr. Fryer, in the last *Chronicle*, respecting his new beautiful Tumbergias, reminds me that now is the right time to grow the varieties of Thunbergia alata, to have fine specimens of them by next April and May. The roots of T. coccinea is the best stock for them, but those of T. grandiflora will also do. Another lot grafted in September will succeed these, and a third grafting in April will keep up the succession for eight or nine months, and the trouble is not half so much as that of rearing seedlings. As the nights begin to lengthen, and the stove plants have made their growths, the house need not be kept so moist as formerly; but diminish the quantity by degrees, and do not syringe late in the afternoon.

Conservatory.—The Tacsonias sent home by Mr. Hartweg, and some of his Passion-flowers also, promise to make good Conservatory climbers. I know two sorts of new hybrid Passion flower—one of which I have flowered—which will likewise do for this house; both are in some of the nurseries, but are not yet named. Passiflora fragrans is almost a failure; although its flowers are sweet and the sweetest, they are too sparingly produced to make a fine display. All Pelargoniums, including the common Scarlets, that are to be forced before next March, should not be stopped or cut in after this time, and all the early struck cuttings of them should now, or soon, be planted out into the reserve garden for a month or two: but as soon as they begin to get too strong or succulent pot them. Another rule to be observed with forcing Pelargoniums is that the pots should be full of roots, or what we call pot-bound, before they are brought into heat; as soon as they throw up for flowering, however, they may be shifted into larger pots, or well supplied with liquid manure. Any person can apply heat and moisture to flowers in winter; but a good deal of judgment and forethought is required to *prepare* the plants: now is the time. *D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Outdoor Department.

Flower gardens are at last becoming a little cheerful, and the plants are rapidly making up for the time lost in the spring. Look over the beds of Scarlet Pelargoniums, and stop the leading branches wherever a flower-bud is perceptible. This will tend to keep the plants dwarf, and the flower-buds will be much increased in size by the concentration of sap. Beds of Petunias and tall-growing Verbenas are frequently much disfigured by being broken about in stormy weather. To prevent this, provide some strong pieces of birch branches and place them in the bed, so as after they are covered, they will support the branches, and prevent their being blown about. Attend assiduously to the removal of all decaying flowers, especially on profuse flowering Verbenas, as Barclayana, Queen, &c., which will do much to prolong their season of bloom; and roll, mow, and sweep the Grass and walks at least once a week.

Rose-tree Garden.—Prepare a temporary pit here, either by building turf walls, or excavating the earth a few inches deep, and forming an embankment round the sides for the propagation of Scarlet and other Pelargoniums; indeed, for all free-striking plants. This pit may be covered with Whitened or oiled canvas, and, if there a three or four inches of light sandy soil for the cuttings to strike root into it, will answer admirably.

Heaths, Pentstemons, and most plants which make branches about the surface of the soil, may be readily increased by placing some light sandy soil about the young shoots, into which they will strike root, and may then be removed into nursery beds.

Pits and Frames.—These structures are now partly stocked with Nierembergias, &c., which are coming forward for another season. Prepare a slight hotbed for a frame, and begin to increase such plants as you require a large stock of next season. Mangles's and other variegated Pelargoniums are generally tardy strikers if left till late in the season; therefore begin in time.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas.—Still attend to the cleanliness of these plants, keeping them free from decayed leaves, weeds, and "the green fly." *Polyanthuses.*—Continue to part in favourable weather; also plant out seedlings. *Tulips.*—Of these little can be said just now. The bed, however, must not be neglected; stir it over, and ridge it up, so that the soil may be sweetened by the action of sun and air. The bulbs in the boxes ought to be thoroughly dry before the loose skins or roots are removed. *Ranunculuses.*—Great attention must be directed towards the roots as they arrive at maturity, which is indicated by the leaves becoming yellow, they should be carefully taken up, as it usually happens that some are ready to remove before others; and all old the roots which have become dormant remain in the ground too long, they are apt to "start," or commence throwing out fresh fibres, which is attended with ruinous consequences. *Carnations.*—The blooming season has now fairly begun, and these favourite flowers will continue to attract admiration during the present and succeeding month. In the south the Exhibitions have already commenced, and will be held, according to the locality, in different parts of England and Scotland, perhaps till the middle of September. As seedlings

bloom, pull up all single or semi-double flowers, as well as all "selfs," unless the variety has some striking characteristic, when it may be worth while to propagate it as a border flower. Commence laying the shoots, taking those varieties first which are in the greatest state of forwardness. Still tie up blds as they advance; and do not let the plants in pots lack moisture —*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—Some of the Montserrats and Black Jamaicas for a winter supply should now be showing. Give these every encouragement by supplying them with liquid manure, and keeping a brisk bottom-heat, with air as the weather permits. Sprinkle the plants frequently, and keep a moist atmosphere during the time that air is admitted. If they are tardy in showing, give but little water till the fruit begins to appear. Be attentive to watering and syringing the young stock, and to the state of the linings of pits heated by dung. Much addition to them will probably not be required at this season, but it is well to be always prepared, should dull or cold weather occur.

Vineries.—In the late vineries, the Grapes which are intended to be kept till Christmas, or after (the best sorts for which are the St. Peter's, Muscat, and Tokay), should be well thinned, to prevent them from moulding in damp weather; and the shoulders of the bunches should be well tied out, to expose the berries as much as possible to the sun, that they may be firm in the skin. Repeat the washing the walls, and flues or pipes, with a mixture of quicklime and sulphur, if the red spider is troublesome.

Peach houses.—Look over the ripening fruit daily, and gather it before it loses its flavour, which it will sometimes do before it drops into the nets placed to receive it.

Fig-house.—Syringe daily where the fruit is not ripening; supply water liberally to the roots, and admit air freely.

Melons.—Maintain a brisk bottom-heat by renewing the linings occasionally. In the pits heated by tanks, if constructed on a good principle, there is the advantage of being always prepared to meet any sudden rise or fall in the external temperature.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Peach-trees.—Proceed with thinning shoots where they are too thick, taking off the laterals, and exposing all the wood you mean to retain for next season, to the benefit of sun and air. *Plums and Cherries.*—On old trees lay in a succession of young wood in all parts of the tree, which being kept close to the wall, will in a few years furnish finer fruit, and produce more plentifully, than can be obtained from old unsightly spurs. *Currants and Gooseberries.*—Shorten the side shoots if not already done. On plants previously shortened, the points of the leading shoots may now be taken off with advantage. *Strawberries.*—Keep the late sorts, such as the "Elton," well mulched with Grass or Straw, to keep the fruit clean. Beds that I covered early with Grass now want covering again. Look after the runners of Keen's Seedling and other early sorts. Where time and labour are not scarce commodities, it is a good plan to lay each runner in a pot, and to cut it from the parent plant when the pot is full of roots; or rich compost may be strewed between the rows to encourage the rooting of the runners. The method I generally adopt is to choose a situation with a good aspect; dig it finely; supply it with a good dressing of old Mushroom dung, or other manure; cut off the runners as soon as they have made two or three leaves, and are beginning to protrude roots; prick them out on the prepared ground three or four inches apart; shade until they begin to grow, and lift with balls either for forcing or making fresh plantations as wanted. The advantage of this system is, that you can clear away all the runners, and the superabundant plants, almost as soon as a plantation has finished bearing; thus affording free exposure to those buds which you expect to produce fruit next season. *Runline* as before.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—The directions previously given regarding summer management, are still applicable for the present time.

Coppice.—The same directions as stated above, are likewise applicable here; but the advantages in regard to profit are greater.

Young Plantations.—It is a great evil to young plantations to allow the hedges round them to grow to a great height before they are cut, by which the side branches of the outside trees are killed, or much injured, and the beauty of the trees spoiled. When this is the case after the hedges are cut, the bare stems are all at once exposed to the winds; therefore, if you do not wish to see through a belt or plantation, and when handsome and useful trees are desired, the hedges should be cut at an early period—at all events frequently cut the inside spray off the hedge next the trees; this will prevent much injury to the lower branches, until the trees are of sufficient height to admit of the hedge being properly cut. On the sides most exposed to boisterous winds, the hedge might be kept higher, and longer in that state, than on the sheltered sides, provided the precaution is taken to trim the insides of them.

Nursery-work.—Attend to previous directions, except that watering and shading are not now wanted, as rain more or less has fallen in most parts of the country, in sufficient quantity for a time to suspend those operations.—*W. B.*

VII.—COTTAGERS' CALENDAR.

Pelargoniums which are now going out of flower may be removed to a situation in the open air, where they will be freely exposed to the sun. In the course of two or three weeks the wood will thus get thoroughly ripened, which will be known by its assuming a brown hue, and the plants may then be cut down and placed in a less exposed situation until they again start into growth. In what state are the summer things sown in the clumps or borders? Spring-sown annuals in many places have come up badly, and in some instances have never appeared at all. The warm and seasonable showers, however, which have fallen lately, have caused the seeds which have hitherto lain dormant to germinate and come up plentifully; but where this is not the case, small patches of such hardy things as Collinsias, Poppies, Convolvulus minor, &c. sown now, will, I have no doubt, flower soon and well, and, intermixing with the herbaceous plants, will render the borders gay in autumn. A correspondent writes—"I have just sown some French Beans, and also some Early Frame Peas, as I imagine this sort will do better than any of the late varieties, for it will come into use sooner, and will consequently be less liable to be attacked by mildew." If the cottager has a piece of spare ground, he had better sow a small quantity of this or some other kind for autumn use. Those who have Broccoli ready for planting had better get them put in soon, as the ground is in good order for their reception. Make room for them by removing crops of Peas or Beans that have ceased to be useful. If sufficient space, however, cannot be got in this way, plant between the rows of Peas, but previous to planting let the ground be well forked up. Plant Celery, and get in a main sowing of Turnips; likewise plant out in drills upon rich ground as many Leeks as may be wanted. Let the drills be about 12 inches apart, and the plants 6 inches in the drill. Brussels Sprouts, Savoys, and German Greens ought also to be planted out about this time. Cucumbers planted out of doors under hand-glasses will now be growing vigorously, and will require strict attention.—*J. McH.*

State of the Weather near London for the week ending July 11, 1844, as observed at the Horticultural Garden, Chiswick.

Notices to Correspondents.

ANTS.—*A Subscriber.*—We know of no effectual remedy for these troublesome little pests. Some recommend arsenic and sugar; others, a solution of corrosive sublimate and treacle; while a third party says lime-water or powdered quicklime expels, but does not kill them. Boiling water has also been tried, and this certainly will destroy them where it can be applied; but that is not often. Perhaps the remedy of most general application is flowers of sulphur. This, says a correspondent, effectually expels them, but does not appear to kill them. After its application, however, he says that they invariably leave the spot, and are not again to be found in the neighbourhood of their late locality. He adds that it affects equally the black and the red Ants.‡

BEES.—*A Lady.*—There is no necessity for having the discoloured combs cut from the centre box; the operation would inflict a serious injury on the brood; and it is not from that part of the hive that pure honeycombs are to be expected. You need not be afraid that old combs will produce weak or small bees. I have a prosperous hive eight years old. However, when the bees happen to die, the bad combs had better be cut out. As the slide was left out, most likely the dead bees found in the drawer died during the winter or spring, which is a common occurrence. But, supposing that was not the case, and that the hive had not swarmed, the old bees would die in the beginning of summer. This applies to the straw hive also, even although it was a first swarm this season; for it would contain old bees from the stock. In some cases intruders cause the slaughter. *J. Wighton.*

BUDDING.—*A Constant Reader.*—Plums are budded in the autumn when the bark runs, and exactly like other plants.

EMIGRATION.—*A Reader.*—The West India Islands are in want of *good* gardeners; but it is doubtful whether good wages can be had. A mere routine gardener would, however, be useless there. If a man would succeed he must thoroughly understand the *principles* of his business. A man who had been a gardener in the West Indies for two or three years would be of more value when he returned than when he went, *provided he contracted no bad habits.*

GRAFTING.—*What do Ants live on?*—It is absurd to suppose that these creatures have hurt your grafts. The work is well done, and the loss of so many of your scions has arisen from the excessively dry weather. Nobody is to blame.

GRAPES.—*J. W.*—Your very old Vine is probably getting worn out, and its roots may be too dry. It is therefore more likely to suffer from a hot sun than are the more vigorous kinds growing beside it; and such has evidently taken effect on the young bunch of fruit received.‡

INSECTS.—*Oakly* says, "Having sown some Swede seed in a flower-pot with some guano, and finding that it grew very slowly, I examined the pot, and found many seeds on the surface in the state which you will see in No. 1, and on opening one, the small fly in No. 2 came out." No. 1 is not Swede seed, but Millet seed; No. 2 is the Thrips, which has no relation to either. Is our correspondent quizzing us?—*B. Chilo.*—We are obliged for the satisfactory packet containing the wasp, flies, &c. *R.* All the questions that have reached us have been answered; but we cannot undertake in all cases to reply on the instant.

NAMES OF PLANTS.—*J. M.*—We do not recognise the leaves you have sent. Your Ferns are 1, Aspidium Filix mas (?), in a young state; 2, Polypodium Dryopteris; 3, Aspidium lobatum; 4, Polypodium Phegopteris.§—*Peter Mackenzie.*—Your Rubus seems a remarkable variety of the common Raspberry.—*Ann.*—Genista tinctoria, var. hirsuta. ¶.—*Inscius.*—Canary Grass.—*J. K. S.*—1, Carex paludosa; 2, Carex remota; no number, Mitella nuda.§—*H. E. B.*—Grewia orientalis.—*P.*—Epidendrum odoratissimum. We have nothing from you unanswered.—*Censorius.*—4. Orobus niger; 1, Cistus salvifolius. Nobody can tell the names of the other fragments. You should remember that plants cannot often be named unless good specimens are supplied.—*F. C. B.*—We really must once more decline naming foreign seeds. You cannot be aware of the enormous difficulty of doing so. Two days would not be enough for the task you propose.—*S. W. W.*—Datura Stramonium.

PELARGONIUMS.—*V. S.*—We can hardly explain your case. We should not refer it to the action of bees or insects, it is most likely to be connected with dryness of the air. We presume you have not described all the circumstances of your case, although no doubt you have intended to do so.

POTATOES.—*S. W.*—The sooner the Potato-blossoms are removed, the better. It is bad physiology to say that if the berries are prevented forming their poisonous matter, that matter will be transferred to the tubers. The materials out of which the fruit forms its poison will be transferred to the tuber, but in another chemical form—namely, that of starch. The Fig-tree bears sugary fruit; if you pull off the Figs, you will not, on that account, get sugar in the branches. The Cherry is red and pulpy; if you remove Cherries, you will not make the branches red and pulpy—and so on.

RHODODENDRONS.—*An Amateur.*—The following are very good free bloomers, and are tolerably hardy:—Russellianum, scarlet; Altaclerense, scarlet; Arbe reum roseum, bright rose; Victoria, deep red; Venustum, pink; Angustum, pale flesh, spotted; Pulcherrimum, scarlet; Grandiflorum (Cunningham's), pale flesh; Macranthum, rose; and Knightii, scarlet. Rhododendrons may be grafted with success in August or September. After the scions are put on, the plants should have a little bottom-heat to set the sap in motion.‡

SOIL.—*W. H. B.*—Provided your soil is stiff enough not to burn, light enough to admit air into its crevices, and thoroughly drained, it does not much matter what its composition is. Equal parts of peat or leaf-mould, loam, and sand, make a good mixture. If a little calcareous matter, such as the plaster and mortar rubbish of old buildings, be added, it will be an improvement.

STRAWBERRIES.—*I. G. H.*—In preparing ground for these, trench it well two spits deep, and manure on the second spit. The beds may be mulched in autumn. Spread the manure on the surface. The autumn rains will wash the substance of it down to the roots, and it will form a clean surface for the plants.‡

TULIP TREES.—*X Y Z.*—These are propagated by seeds imported from North America. If your tree is in health, why manure it? If you will not let well alone, employ good rotten farm-yard dung, dug into the ground as far from the bole as the ends of the branches.

VARIEGATED BEECHES.—*J. H. Haycroft.*—This is very distinct from the old Variegated Beech, and desirable if constant¶, for the gratification of those who admire variegated plants, which we do not in general.

WHITNEY'S COMPOSITION.—*J. G. H.*—Good calico is the best for this material. An Arnott stove will keep the frost out of a small house; but you must take care not to work it without a pan of water on the top.

MISCELLANEOUS.—*Icenus.*—Certainly, Berberis fascicularis is no twiner; nor can we find any statement that it is so in the page to which you refer.—*F. X. O.*—Your Erica tetralix aurea is uncommonly ugly. Do you mean to say that the roots of your Teasel plants have contained three pints of water each.—One shilling each will be given for No. 7, 1842, and No. 2, 1843.—*A. M.*—When your seedling Strawberry reached us it was quite rotten, and consequently in an unfit state for forming any opinion in regard to its merits.‡—*B. Chilo.*—We shall give our opinion on the merits of your Picotees if you send them.*—*Querist.*—Gentianella may be increased by dividing the plants early in autumn. The cutting of Asparagus should never be continued beyond midsummer; apply salt to the beds when the summer shoots are growing (see p. 444 of last week's Paper). Where seed is not wanted, the seed-vessels should always be taken off Rhododendrons as soon as the blossoms drop, for reasons previously given. Daphne Cneorum is propagated by layers. Annuals do not flower better for being sown in autumn, but they flower earlier next spring. Crops are benefited by having the soil stirred up between the rows in dry weather.‡—*Conifera.*—Abies Smithiana and Pinus Cephalonica are both perfectly hardy‡—*Delta.*—Trap the blackbirds with rat-traps, baited with Cherries. The mode of preserving Gooseberries, Currants, &c., mentioned at p. 821, 1842, is as follows:—Take wide-mouthed glass, or, if possible, stone bottles; fill them by shaking, or even, if you like, by pressing them or mashing them with a round stick like a ruler. Then cork them tight with the best corks (for good corking is more than half the battle), using good deep chives, as they are called; wire down the cork strongly, and insert a small slip of wood between the wire and cork. Place the bottles upright in a boiler, filled with cold water, up to their necks; heat the water until it boils; keep it boiling ten minutes, and then withdraw the fire, or move the boiler off it. When the water is cool take out the bottles, and they will keep for years. They may be rosined; but with good corks it is needless, and is afterwards troublesome.—*A. E.*—We must beg to refer you to the numerous statements made on the culture of the Double Yellow Rose in previous volumes, particularly in a Leading Article at p. 811, in the vol. for 1841.‡—*Anne.*—Your specimen of a Carex piercing the root of Gymnadenia conopsea is curious. We have such a case with Couchgrass and Potato.

SEEDLING FLOWERS.

CALCEOLARIAS.—*Thos A.*—Your seedlings are small, and inferior in the marking to the seedlings of the present day. Gipsey is the most uncommon.*

FUCHSIAS.—*J. B., Durham.*—Your seedling is a finely-formed flower; tube and sepals of the most delicate pink, approaching to white; corolla rose, with a slight tinge of purple: a clear and brilliant flower, the best of its colour we have yet seen.*—*H. M.*—None of your seedlings are improvements upon varieties already in cultivation, and they are all deficient in the colour of the corolla.*

GLADIOLI.—*E. H. Krelage, Haarlem.*—Your seedlings appear to be crosses between G. cardinalis and G. blandus, the former variety predominating most in the offspring. They are very beautiful, like all such crosses. The colours range from very pale red to a deep rich vermilion. Many, however, bear too strong a resemblance to each other, the difference of colour being very trifling; and in two or three instances the form of the flower is not good, the petals being very narrow. Eclatante frappante is an example of want of form. Seedling No. 41 is a rich, splendid, and distinct colour; and Lord John Russell, Prince Albert, and Queen Victoria are very good varieties of a pale colour. We should say that seedling No. 41 is the cream of the batch. All are wonderfully well grown. A selection of the most distinct varieties would be acceptable to any garden.

PANSIES.—*T. C.*—No. 1 is a flower of good form and substance, but the faint and uncertain colour in the top petals is objectionable. 2, white pure, eye clear and well defined, flower flat, edges are a little too uneven. 3 is an inferior flower, and wants the blotch on the side petals to complete the eye. 4—the shield, or centre, of this flower wants defining, and the lip is too small, in proportion to the other petals. 5 is your best flower—round, flat, and of good substance; the side petals meet closely above the eye, the proportion of the petals is very fine, and it is more novel than the others.*

PELARGONIUMS.—*I. D. J., Brussels.*—Your seedlings are generally deficient in one property, regarded in the present day as essential in constituting a fine flower—viz., form. In substance they are very good, and in colour some of the varieties are fine, such as 480, 481, and 460; the colours of these are high and fine; 415 is also clear and good. 285 is an improvement in the form; the under petals are short and broad, but the colour is poor and uneven. Your flowers generally are small, and wanting in form, compared to the varieties raised of late years in this country.*—*P. F.*—There is nothing remarkable in your seedlings; they are common in colour, with the top petals rather pointed, and the bottom ones too narrow. 12 and 10 are the two best; the latter is a repetition of Matilda, with a fine spot running to the base of the petal.*—*R. W.*—Rembrandt is a bright and very pretty seedling; from its colour and firmness of petal well adapted for bouquets; it is deficient in form, compared to recent varieties.*—*W. R., near Devizes.*—Both your seedlings are pretty flowers; No. 7 is the better form; 10 has fine top petals, but the bottom ones are rather too long; both are good in colour.*—*J. W.*—Your seedlings from P. tricolor are pretty in colour, but the flowers want size to render them desirable.*

PETUNIAS.—*W. R., near Devizes.*—Of your seedlings, No. 2 is the best; the colour is rich and fine, and the flower well formed. No. 1, though showy, is not uncommon in colour; and the divisions in the corolla are too deeply indented. Compare the form of this with No. 2. 3 and 5 are not rare, though rich in colour; and 4 is common. P. punctata is a variegated variety.*

PICOTEES.—*P. W.*—Your two seedlings can only be regarded as border varieties.*

PINKS.—*R. B. B. B.*—The serrated edge is the great fault in your Pink; in other properties it is very good; the pod is well formed, white pure, colour rather novel, and the lacing perfect.*

POTENTILLAS.—*J. M.*—If the supposed origin of your flower from P. leucochroa is true, then it would seem to be a cross between it and P. atrosanguinea. Is it any improvement on the latter?

ROSES.—*W. W. & S.*—Your seedling Gallica, named *Margaret Mary*, is a handsome variety—fine in form, being compact and very double, with the outside petals finely cupped; in colour it is of a purple rose, of a peculiar and beautiful tinge; it is fragrant, and at its best when fully expanded; this is owing to the bud not being handsome in form, and one or two of the petals having a bruised appearance, which may probably arise from the season, or accident. The foliage is of a deep, rich green, short, and very handsome.*

***As usual, many communications have been received too late.

SEED-WHEAT.—Any one desirous of purchasing Seed for next year is invited to inspect the two varieties of Wheat, SHIRREFF'S HOPETOUN and MORTON'S RED-STRAW WHITE, 126 acres of which are now growing on WHITFIELD FARM, THORNBURY, GLOUCESTERSHIRE.

The present is the only season of the year when the value of any variety of Wheat as Seed can be ascertained by inspection; for, if the examination of a mere sample of the grain, which can be seen at any time, be nearly uninstructive as to its quality in the eye of the baker (see *Ag. Gazette*, No. 8), it is entirely so as to the productiveness or habit of growth of the variety to which it belongs. These points, which are of the highest importance in the eye of the Farmer, can be ascertained only by an examination of the growing plant when in full ear.

JOHN MORTON, Whitfield, Thornbury.

The Agricultural Gazette.

SATURDAY, JULY 13, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday,	July 17	Agricultural Society of England.
Thursday,	July 18	Agricultural Imp. Soc. of Ireland.
Tuesday,	July 23	Meeting, Implement, and Cattle Shows of the Agricultural Society of England, at Southampton.
Wednesday,	July 24	
Thursday,	July 25	
Friday,	July 26	
Thursday,	July 25	Agricultural Imp. Soc. of Ireland.

FARMERS' CLUBS.

July 23	Richmondshire.	July 27	Cardiff.
	Grove Ferry.		Gloucester.
July 26	Debenham.		
	Stoke Ferry.		
	Haleeworth.		

Doubtless most of our readers have heard of the Agricultural Museum at Stirling, established and conducted by Messrs. Drummond and Sons. That institution has not only been of immense benefit to the agriculture of the district in which it is placed, but it has, through its numerous visitors, greatly furthered the progress of good farming generally. Now, all the advantages which this establishment has conferred on Stirlingshire, may equally be secured for any district in the kingdom by any one who will adopt the simple measures necessary for the purpose. And should any one feel desirous of making such a patriotic attempt, having made inquiry as to the steps taken by the Messrs. Drummond in the early history of their Museum, we publish the result for his information.

But first let us direct attention to the following statement by S. D. Stirling, Esq., of Glenbervie, which he, as a Stirlingshire landlord, gives of the advantage of this Institution.

"In reference to the following statistics of the Stirling Agricultural Museum, I shall notice a few of the advantages which a wide district has derived from this establishment; and which are equally within the reach of any district where the landlords choose to give a helping hand to those whose interest in the land is as great, though not as permanent, as their own. A detail of these will be the easiest mode of pointing out what are the requisites for the successful establishment of such an institution. The Messrs. Drummond possess a practical knowledge of all matters connected with agriculture and horticulture—this is one requisite; and they are ever ready, either themselves, or by the aid of their numerous friends, to test the value of any alleged improvement either in seeds, roots, or agricultural implements. Thus quackery cannot go long undetected, and the farmer, by seeing a great variety of the articles he may require, and having access to the opinion of those who, being unbiassed, have properly tested their respective merits, is able to judge what will best suit his wants or his means. Another advantage of this institution lies in the emulation which is excited amongst the tradesmen who supply the different implements to the Messrs. Drummond; for if the articles furnished by one are in any respect inferior to those of his neighbours, either in material, form, or workmanship, the want of demand soon puts all to rights. Messrs. Drummond also spare neither trouble nor expense in procuring such implements as are most approved from every district, however distant: they have thus obtained for their Museum such a name that orders are sent from distances to which the cost of transit alone would appear to be an insurmountable obstacle. To this Museum all are admitted, and the uses and merits of each article exhibited are explained; nor does this attention always go unrewarded, for much useful information is often obtained from casual visitors, which is again circulated; and an extensive connection is thus formed, through which all questions respecting agricultural matters are readily answered.

"There is also a large collection of Grains and Grasses in the straw, from which many a useful lesson is to be learned; and being labelled in a manner to be understood by the agricultural classes generally, to those who may have been charmed and misled by fine names, it becomes evident that Anthoxanthum odoratum and Cynosurus cristatus are neither more nor less than sweet-scented Vernal and Dog's-tail Grass, generally too prevalent in soil which they affect, and too unproductive to deserve to be placed where they can be kept out. It is also explained which Grasses are best suited for particular soils and particular purposes; which varieties of Grain are best adapted for situations where the crop may be expected to lodge, and, where this is inevitable, which will suffer least from being laid. Specimens of root-crops are also annually sent to this Museum by the agriculturists, and their different merits are freely commented on; and whereas, at first, size was principally aimed at by exhibitors, good shape to turn the rain, and specific gravity, as indicating solidity, are now considered of more importance.

"It would be tedious to enumerate all, or nearly all that is to be found in this Museum, which has been collected by the unwearied attention of the Messrs. Drummond; suffice it to say, that it is calculated to exert as useful an influence as any establishment of the kind in Europe, and that to it the district and Scotland is much indebted for its advanced state of agricultural improvement."

The following is the answer of the Messrs. Drummond to an inquiry into the statistics of their institution:—

"It was chiefly from witnessing the advantages resulting from collections of vegetable productions at Horticultural Shows, and from observing the interest excited by fine specimens of Agricultural produce, which were occasionally sent to their premises for exhibition, that W. Drummond and Sons conceived the idea of affording, as far as possible, an opportunity for such exhibitions on an enlarged and regular plan.

"The following is a copy of their first circular:—

"'*To Agriculturists.*—It is proposed to exhibit at the premises of W. Drummond and Sons, Stirling, on the 11th of November next, and the three succeeding weeks, specimens of all the varieties of Turnip, Carrot, Potato, and other roots and seeds connected with the agriculture of this district. Such specimens will be received from any quarter, betwixt this and the above date; and as it is of importance to have these productions properly labelled, it is very desirable that they should be accompanied with a note stating the name of the variety, by whom grown, the weight or measure of each, the produce per acre, description of soil, and the kind and quantity of manure applied, &c. Those interested are respectfully invited to an inspection. — *Stirling, September* 27, 1831.'

"The proposal was promptly and well responded to, for at this first essay there were above 80 lots of roots, and 160 specimens of grain, also a few implements shown. The contributors were above 200, the visitors several thousands, of all ranks.

"A Report of the Exhibition was published in December, 1831, wherein it is remarked, that in matters of substantive fact there are no means of acquiring knowledge so convincing and abiding as those afforded by the eyes and the hands, and that men cannot form just ideas of the relative value of any subject without comparison, and the more extensive in number and condensed in position the subjects of that comparison are, the more evident and correct will their relative characters appear. In agriculture, such opportunities of comparison had hitherto seldom occurred, but it was hoped that this Exhibition would form the germ of a system destined to grow and flourish. Early in the succeeding year (1832) circulars containing a fuller prospectus and details were issued. The specimens shown were multiplied and varied, with a more specific and correct labelling. The interest excited and number of visitors increased. This second Exhibition continued from 16th November till 16th March following. A report, with communications, was thereafter published. In the Preface it is observed that, "To speak of the merits of this mode of circulating agricultural knowledge is rendered unnecessary by its already felt advantages, and by the cordial approval of competent judges. The machinery of such Exhibitions being of the most simple kind, may easily be adopted by any agricultural association." The third year (1833) the Exhibition was commenced earlier, on account of the Highland and Agricultural Society of Scotland holding its annual meeting in Stirling that year. The collections of specimens and implements, &c. far surpassed the preceding ones, and were inspected with approval by the thousands of agriculturists who attended the great meeting, and the Directors of the Society soon afterwards signified their approbation by the award of their Gold Medal to 'Messrs. Drummond, in approbation of their having originated an Exhibition of seeds, plants, and other specimens useful in the operations of practical agriculture.'

"A third Report was published, and the Exhibition rendered permanent under the designation of an Agricultural Museum or Repository. With this Report were given also several excellent communications, particularly Remarks on thorough Drainage and deep Ploughing, by Mr. Smith, of Deanston; by which and by his valuable counsel and assistance in the whole undertaking, that gentleman has eminently contributed to its success. It happened most opportunely also, that spirited and well-conducted improvements were in progress at Polmaise, Glenbervie, Keir, Blair-Drummond, and other estates in the neighbourhood, the proprietors of which have ever given their most cordial and efficient support.

"The Agricultural Museum, in connexion with the Warehouse, has continued to prosper the connexion being of mutual advantage; for the Warehouse contains full-sized implements, &c., daily coming in, and exhibits the successive improvements of various makers; it prevents the stagnation which must more or less take place in the interest excited by collections of mere specimens and models; the demand, too, which here takes place for particular seeds or implements affords a fair and therefore a useful test of their value.

"In 1840, for the better conducting of the establishment, a large building was designed and erected, consisting of four halls or floors, each 160 feet in length, and 20 to 25 feet in breadth; the two uppermost being chiefly allotted to the Museum, the two undermost to the Warehouse; and in December, 1843, an Agricultural Museum and Warehouse, in connexion with their Stirling one, was opened by Messrs. Drummond and Sons, in Dublin, which has met with the greatest encouragement.

"The number of visitors has nearly doubled within these few years, and may now average 1000 per month, including many strangers, and often foreigners, who visit Stirling in their route, and gentlemen connected with agriculture, who frequently come from a distance on purpose to inspect the collection and the farming improvements of the district. The frequent and careful inspection, and the purchase and trial of new and improved seeds and implements, which might not otherwise have come under observation by those active as improvers, afford ample proof of the value of the Agricultural Museum in helping them forward. And very seldom indeed have any, although not naturally improvers, been found so apathetic, on viewing the whole collection, as not to feel and express an increasing interest in its objects.

"In regard to the matter of finance, or the support of the Museum as distinct from the Warehouse: after the first three years, the outlay having become considerable, a small fund, the proceeds of admission tickets and subscriptions of agricultural friends, contributed partly to the expenses; but, business transactions increasing its maintenance, this had for a number of years been thrown wholly on the profits of the Warehouse, which are derived not from higher prices, however, on the goods—as they, equally with those of other salesmen, are exposed to competition—but by extent of business conducted with economy and attention."

The concluding paragraphs of this statement are worthy of attention. It appears that this Museum has not only been a source of profit to the neighbourhood in which it is placed, but also, through its visitors, who naturally become customers, to the spirited proprietors of it. This is a very important point, and one which justifies the anticipation that much of our future progress in agricultural improvement may be owing to the operation of Museums of this description, hereafter to be established by seedsmen, agricultural implement makers, and others, over the extent of the country.

No *additions*, whether through the aid of scientific men or otherwise, to our present knowledge as farmers, valuable though it might be, can exceed in national importance the benefits which would follow the universal diffusion of what is already known, though it be by few; and this can only be obtained through the influence of example farms and *Agricultural Museums*.

After a season of unexampled drought the country is at length blessed with refreshing rains. The effects of the weather we have experienced are reported as follows:—Wheat has not suffered much injury except on light and shallow soils. A gentleman who has lately travelled through the counties of Essex, Herts, Bedford, Northampton, and Lincoln, and through Buckinghamshire, Oxfordshire, Berks, and Gloucestershire, informs us that if it be harvested well, he anticipates a full average crop. In Scotland again, where the weather does not appear to have been so dry, still less injury, if any, has been done.

With regard to all spring Corn, however, a very different report is given. Beans and Peas will be a very poor crop; Oats and Barley will not only be comparatively unproductive per acre, but the breadth of land sown, especially of the latter, is much less than usual—farmers having in many cases delayed sowing till too late, in the hope of wet weather.

The Hay crop is one of the lightest ever known; and less than the ordinary extent of Grass has been mown—much that was intended for Hay having been required for the cattle, owing to the failure of the pastures.

The Potato crop is in many districts a failure; many cases are reported in which the seed has been sown twice, but has never sprouted. Turnips, though sown late, or rather through brairding late—for the seed may have lain dry in the ground for weeks—may yet yield a plentiful crop if the weather be favourable. Mangold Wurzel, in all cases which we have heard of, is a failure: the dry weather set in just at its seed-time.

The most favourable account that can be given of the present condition of the farmer's prospects, is that if the weather be suitable, the Wheat crop will probably be early and plentiful, and that we may yet have good crops of Turnips, and of aftermath Grass.

The accounts of the appearance of the crops in Scotland are generally more favourable than those from most districts in England.

EFFECTS OF CHARCOAL AND SALT ON THE SWEDISH TURNIP.

HEREWITH I send you three plants of Turnips, (Skirving's), sowed on the same plot of ground, at the same hour of the same day. In the case of the largest specimen, the seed was well mixed with about twelve times its bulk of charcoal-dust. In that of the next size, the seed was mixed with five times its weight of common salt, and nine bulks of charcoal; and in the case of the plant just come up, the seed was put in quite alone. In all three cases the seed was put in drills in soil which last year bore Mangold Wurzel in seed, and the year before Wheat, and no manure has been applied since. My object in using the charcoal and salt was from the consideration that both substances are powerful absorbents and retainers of moisture, as well as direct food for plants.

Nos. 1 and 2, in spite of the parched state of the ground, (the 3rd June) came up strong in five days, and continued growing; No. 1, however, soon and rapidly taking the lead. At the end of a fortnight all three rows were once watered, which however failed to bring up the seed sown without anything. When our first rain came heavily, ten days ago, No. 1 grew almost visibly, and three or four days after, No. 3 just began to show. I may also state that I sowed Belgian Carrots with charcoal only, the first week in May, and though the soil then was quite dusty, and so continued until ten days ago, the plant came up well in three weeks, which is at least ten days sooner than Carrot seed usually comes up, even under favourable circumstances as to rain. I sowed one more row of the Turnip, with a double quantity of salt, which seems to have destroyed the seed, as none has yet appeared. If you think these experiments worth noticing in your excellent Journal, you are quite welcome to do so, and I shall feel happy if so simple a substance should prove of use in forcing a plant of Turnips, or other roots.—ESSEX, *Cassiobury, Watford.*

[We are exceedingly obliged to the Earl of Essex for this interesting communication. Of the specimens sent, No. 1 appears to be a plant which has had about six weeks' vigorous growth; No. 3 has not yet acquired its rough leaf; and No. 2 is of a medium size. This extraordinary difference in plants sown at the same time, on the same plot of ground, appears to be wholly owing to the simple means adopted, as described above, which, from his Lordship's experience, certainly appear to be well worthy of extensive trial.]

SKETCHES OF EAST LOTHIAN HUSBANDRY.

3. HOEING IMPLEMENTS.—These include the several instruments employed in tilling and pulverising the intervals of plants cultivated in rows. It has been already stated that some of the cereal Grasses, particularly Oats, were, under peculiar circumstances, sown in rows. The implement most commonly employed in tilling the intervals is the hand-hoe; but where the system is practised to any considerable extent, a machine drawn by one horse, consisting of a series of flat triangular shares, nearly as wide as the intervals in which they are to move, and attached to a frame supported upon wheels, is sometimes employed. This implement in its present imperfect condition is not found easily manageable or very efficient, and is therefore but very seldom used.

A hoeing implement of general use is the small paring-plough already referred to. Its purpose, as its name implies, is to pare away a slice of earth from the sides of Bean, Potato, or Turnip drills, before horse-hoeing or grubbing the intervals. The other implements of this class are several kinds of drill-grubbers, horse-hoes, scufflers, &c., designed to follow the paring-plough, and further to reduce the soil pared from the drills, and to drag to the surface weeds of every description. Drill-harrows with attached hoes of various shapes, were until lately much used for these purposes, but are now nearly altogether dispensed with, at least on the heavy clay farms; the drill-grubber, an implement with cutters only, being found to perform more effectually the double purpose of dragging weeds to the surface, and of pulverising and tilling the intervals between the rows of plants. The drill-grubber, it may also be remarked, frequently supersedes the use of the paring-plough. The operations of the drill-grubber are chiefly confined to Bean and Potato culture; a lighter implement with teeth similar to those of the common harrow, rather appropriately termed a scraper, being generally used for Turnips.

4. BARN MACHINES.—East Lothian has the undisputed honour of being the county in which the *Threshing-machine*—decidedly the most valuable rural implement ever invented—was first originated and employed. Threshing by the flail is now almost, but not altogether, unknown here. I am aware, however, of only one solitary instance of a farm in the Lowland district in which this rude instrument is still used, but it is very common in the Lammermoor district, as the quantity of Corn grown there upon any farm does not warrant the expense of erecting a threshing-machine. The usual size of the machines employed on farms of from 300 to 500 acres is that requiring the power of six horses to propel it. Machines driven by four horses are used on arable farms under 300 acres, where any one is used.

Threshing-machines, on the larger class of farms, are now generally driven by steam-power. Water, as being even still more economical, is preferred and used where a sufficient supply of it can be had; but where this is not the case, steam-power is employed. Wind-driven machines were, until lately, very numerous; but this, as well as the most expensive and objectionable of all—horse-power—has gradually given way to the steam engine, which has been found to be much more uniform and expeditious in executing its work than either. In 1805, when Somerville wrote the Survey of the County for the Board of Agriculture, there was but one threshing-machine in it driven by steam, but farm-engines are now so numerous, that Sir Thomas B. Hepburn, member for the county, has been somewhat appropriately styled the representative of tall chimneys. The engines most commonly used are what are termed high-pressure, or non-condensing; condensing-engines are also employed on some farms, but they are not so simple or so cheap as the former. Six-horse-power engines are the most numerous, although, on very large farms, eight-horse-power engines are not uncommon.

The chief advantages of steam power arises from its great economy, particularly in a locality where coals are abundant and cheap. A cart-load of about 15 cwt. of small dross coal, purchased at the colliery for a shilling, will, in ordinary cases, supply with fuel a six-horse-power engine for 10 hours, during which time from 35 to 45 quarters of grain may be threshed. The quantity threshed in a given time will, of course, depend upon its quality and the length of the straw; but under favourable circumstances, and with an average quality of grain, from 4 to 5 quarters of Oats or Barley, and from 3½ to 4½ quarters of Wheat, may be threshed in an hour. Little need be said here about the threshing-machine itself, as it is now well known to every person engaged in agricultural pursuits. Alterations and improvements have, no doubt, been made in some localities on certain parts of the machine, but all its essential parts, and the principle of its construction, are the same everywhere.

When the threshing-machine is made to be driven by water, it is usual also to have a horse-course and apparatus attached, for the purpose of applying horse-power when a sufficient supply of water cannot be obtained. By varying the positions of the pinions on the common shaft, which communicates with the horse and water-wheels, either power can be used separately, or both may be combined when the water is unable to propel the machine alone.

The number of persons requisite for working a threshing-machine of the usual size—a six-horse-power—is generally seven—four women and three men. Two women loosen or unbind the sheaves and lay them upon the feeding-board, to the man who supplies them to the machine, and other two women are required in the ender or corn-barn, to remove the grain as it falls from the fanners attached to the threshing-machine. Two men are necessary for carrying away the straw ejected from the machine, to be piled up for use either in the straw-barn into which it falls from the machine, or in the stackyard. Wheaten straw, to be used as litter, is generally conveyed at once to the yards in which it may be required.

A threshing-machine and all its necessary appendages, together with a six-horse-power high-pressure engine, may now be erected for about 150*l.*

Winnowing-Machine or Fanners—The winnowing-machines are nearly the same as those in general use in other parts of the country, and therefore do not require any lengthened description in this place. One pair of fanners is invariably attached to, and driven by a leather belt or chain from the threshing machine. Besides this one, which separates the chaff from the grain before coming to the ground, another is used for dressing or preparing the grain for market, generally worked by the hand, but frequently also by means of a belt from the machine. Instead of the wire sieves so commonly used in the interior of winnowing-machines, a strong canvas cloth revolving upon two wooden rollers is by some farmers preferred and employed. From six to seven quarters of Oats is the usual quantity which can be once winnowed in an hour, by a machine in good order, and actively worked. Best fanners, with sieves and riddles, may be had for 8*l.* to 8*l.* 10*s.*

The only other machines belonging to or worked in the barn, are a *Hummeller* for the purpose of separating the awns from the grains of Barley, and a machine for bruising Oats, Peas, or Beans, for horses or other animals, both of which are driven by the same power that propels the threshing-machine. The threshing, hummelling, and winnowing of Barley always proceed simultaneously, but the bruiser is seldom worked with the other machines, as the motion necessary for threshing is considered to be too rapid for the purpose of bruising properly. Besides the machines already mentioned, a churn and a straw-cutter are also not unfrequently worked in connection with the threshing-machine.

5. WHEEL-CARRIAGES OR CARTS.—Every farm is provided with several kinds of carts, each adapted to some particular species of work; some are in daily employment while others are used only on special occasions.

Single-horse Carts.—Formerly, on account of bad roads and other causes, none but two-horse carts were used in this county, for the different purposes of farming, but single-horse carts are now generally preferred and more frequently employed, especially in long journeys, conveying Corn to market and coals from the colliery, &c. The superiority of the single over the double cart, consists in being much lighter, more steady and compact, and consequently less shaking and burthensome on the shaft-horse. The majority of single-horse carts are made with the body permanently fixed to the shafts; this construction being supposed to render the cart more steady and compact than the turn-up or coup-cart. In the economy of the farm, every ploughman has the charge and management of a pair of horses, and when carting, he drives them both himself. When using single carts, one follows the other, the horse of the last cart being fastened by a short rope from his bridle to a ring in the hind-door of the foremost cart. These carts are usually 4½ feet in length inside the boards; 3 feet 2 inches in breadth at bottom, and 14 inches deep. Price, with wheels and axle, 9*l.* 10*s.* to 10*l.*

The Double-horse Cart differs little from the single cart except in being larger and stronger. It has sometimes a fixed but most generally a turn-up body. Double-horse carts are now employed only in carting out dung from the yards to the fields, earth or other heavy materials. Although single-horse carts are, beyond a question, the most economical and profitable for general purposes, experience has fully decided that the double-horse cart cannot be altogether dispensed with; and is invariably used for conveying dung to the fields during winter, when farm roads are not generally in the best condition. A two-horse cart is commonly 5 feet long within the sides, 3½ feet in breadth, and 17 inches high. With side-boards it will contain, if well filled, about two cubic yards of dung. Price, with wheels and axle, 10*l.* 10*s.* to 11*l.*

The Corn-cart consists of a sparred frame-work, with the bottom and part of the sides boarded, and is used solely for the purpose of carting Corn in the sheaf, hay, or similar materials. When being employed, this cart is mounted upon the wheels and axle of any of the close carts, and may be drawn by one or two horses according to circumstances. No species of cart is better adapted to the purpose for which it is intended than this. None admits of a larger load with the least possible trouble to the driver or horse. The only alterations or improvements lately effected in the construction of the Corn-cart consist in making the body wider and dispensing with the usual side-rails. Corn-carts of this description are now much used in the hill-district; they have no side-rails; one cross-rail supported upon two upright iron stays prevents the Corn from falling forward on the horse, and two semicircular bars of iron-halves of wheel-rims answer the purpose, serve to keep the wheels from disturbing the load, and support a strong board nearly bisecting the cart, on which the driver stands while forking the sheaves to the stacker. The object of this form is to render the cart less liable to be overturned in uneven situations. In some of the Corn-carts now made, the rails are so fitted to the body, that they may be taken off and replaced at pleasure, and the body used for carting wood, &c. The usual dimensions of the Corn-cart are—length of rails, 10½ feet; height of spars, 20 inches; breadth 5½ feet.

Cart-wheels are generally 4½ feet in diameter; cast-metal naves were in much vogue some time ago throughout the county, but have now fallen into disuse. Great attention is paid to the fitting of the axle.

In this hasty sketch of the principal implements and machines in general use here, I have omitted even to name a very considerable number of others of minor importance, but the most of them shall be noticed when I come to speak of the different operations in which they are employed.—*T. Sullivan.*

SCIENTIFIC EDUCATION.

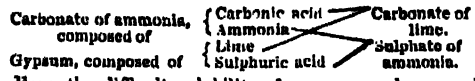
THE following account of the half-yearly examination of the scholars of Messrs. Nesbit, of Kennington House Academy, abridged from the *Maidstone Gazette*, is inserted here with the view of placing before our readers Dr. Reid's excellent remarks on the value of a scientific education even to those who may only receive from it an *indirect* benefit. Of how much greater value must it be to those who, like the farmer, daily superintend operations dependent for their success on the favourable development of scientific principles!

At the hour appointed for the examination, Dr. D. B. Reid, F.R.S.E., took the chair, and the schoolroom was completely filled with a respectable audience. After a short address from Mr. J. C. Nesbit, various literary selections were recited by some of the pupils. A very satisfactory examination in geometry, by J. Imray, Esq., M.A., was then conducted, and after an extended examination in geology, by Mr. Richardson, of the British Museum, one of the young gentlemen, assisted by the members of the Chemistry Class, delivered a short lecture on chemistry, and was highly complimented by the chairman and applauded by the audience.

Dr. Reid, in the course of his remarks, after the conclusion of the recitations and examinations, said no one felt more desirous for the promulgation of a knowledge of modern science than himself. Where he had received his education, there were upwards of 200 boys in his classes, and upwards of 800 altogether in the school, and he had had the good fortune to meet

with some 50 of these in after life, and whenever their conversation recurred to the scenes of their early days, their exclamation had constantly been, "Oh that we had had the same opportunities of acquiring modern languages—the same facilities for acquiring scientific knowledge—which exist in these days! How much we should have been enabled to do which we have been obliged to leave undone! How much more might we have appreciated, and perhaps contributed to, those splendid realities in physical science which are now shedding their beneficial influence over every country of the globe!" When he and his old associates looked back upon their own difficulties, it was doubly gratifying to them to witness the advantages which were placed within the reach of their young friends, whose exertions had afforded the audience so much pleasure in the course of the evening. From what he had seen he could not doubt that they had felt much delight in acquiring the knowledge they had displayed. He could fully appreciate the delight of all persons who loved the promotion of education, at the successful results they had seen of the attempt to combine the knowledge of foreign languages and modern science with the usual branches of education. It was to an improved knowledge in these branches of education that they must look for an extension of that intercourse, and a strengthening of those bonds of mutual sympathy, which were calculated, the more they were extended, to connect man with man, in the pursuit of objects of the most elevated kind. He could not pass over, without particular notice, the chemical lecture which they had heard from one of the pupils. He could not recommend too earnestly to the young persons present the necessity of acquainting themselves with chemical science. That young persons might do so, had been most successfully demonstrated on that evening. The cultivation of the love of science in young persons was of the highest importance, even if it had no definite purpose in connexion with their pursuits in after life, which it sometimes influenced materially. The difference between youths who had been thus educated and those who had not, was apparent to the most superficial observer. Their mode of thinking, and even the tone of their conversation, were influenced by this mode of training to a very great extent, and he was satisfied that the great exertions of their teachers would be appreciated more and more as their pupils advanced in life, and found the immense advantages of their education on the principles adopted in this school, which would entwine themselves with all their habits and associations, as well as with the varied duties to which their future occupations might lead them. Physical science was universal in its operations, and necessarily embodied everything that was associated with the useful arts, as well as with the comforts and elegancies of life, and in one department, viz., agriculture, the young pupils preparing for this profession would only be astonished as they proceeded, at the long and lingering slowness with which the farmers had hitherto taken up and applied that knowledge, particularly of chemistry, which gave significant proof that it would soon do as much for agriculture as it had already achieved for arts and manufactures. Those who had not been thus educated were frequently consuming their time unprofitably both to themselves and others. But when acquainted with science, young persons were constantly engaged in the discovery of new facts, or in some inquiry which had for its object the pursuit, development, and demonstration of truth.—*M. S.*

ON LIQUID MANURE.—No. II.



In pursuing the subject of the best and most economical ingredient for fixing the ammonia generated during the putrefaction of urine, we next come to sulphate of lime, known as gypsum, plaster stone, alabaster, or plaster of Paris; it exists abundantly in many parts of England, and is composed of—

Lime	28.5
Sulphuric acid	40.0
Water	18.0
	86.5

If gypsum be subjected to a red heat, it parts with its water, is easily reduced to powder, and is known as ordinary plaster of Paris: in this state it has a great affinity for water, readily combining with it, and in a short time setting into a hard mass. Sulphate of lime is sparingly soluble in water, at ordinary temperatures; 500 parts of water only dissolving one part of sulphate of lime. It exists in some soils, and is dissolved by rain water as it sinks through the earth. Hence it is found in the waters of many springs and rivers, and it is frequently the cause of hardness in water.

Gypsum strongly recommends itself to the English farmer, from the low price at which it may be obtained, as a means of converting the volatile carbonate of ammonia contained in putrid urine into a sulphate of ammonia, which is not volatile. But to insure its producing this effect, it is necessary that it should, in the first place, be reduced to an impalpable powder, since it is only when in solution that gypsum can be decomposed by a solution of ammonia, and as it is so sparingly soluble, every precaution is necessary to insure success; and since, the finer the powder it is reduced to, the more readily soluble does it become, it is necessary that this point be closely attended to. If it were only crushed or coarsely ground, it would be in vain to expect it to become soluble, or to fix the ammonia. It is also necessary, in the second place, that the powdered gypsum be frequently raked up from the bottom of the vessel or tank in which it is used, since it is only by frequently bringing it into contact with fresh portions of liquid that the solution is effected.

When gypsum is once dissolved, it readily undergoes decomposition with the ammonia contained in the urine. This occurs in the following manner:—The sulphuric acid, which is in combustion with the lime in gypsum, quits the lime and combines with the ammonia, forming sulphate of ammonia; while the lime, the other constituent of the gypsum, combines with the carbonic acid which was in combination with the ammonia before the formation of sulphate of ammonia, and forms a carbonate of lime or chalk; this subsides to the bottom of the tank, and will require to be removed occasionally; the following diagram will show the change which occurs in the constituents:—

From the difficult solubility of gypsum, only a small portion of it can be taken up in solution at any one time, which portion soon undergoes decomposition, and may be replaced by another portion, and so on until all in its turn has become soluble, and undergone decomposition, this change being greatly facilitated by frequent agitation; in fact, without it, the gypsum would remain at the bottom of the tank as an inert mass, while the ammonia would continue to escape from its surface and be lost. From a series of experiments I have lately conducted to ascertain the relative power of different substances to form fixed salts of ammonia, I found that it required several days before the ammonia in putrid urine was effectually converted into a sulphate by the use of gypsum reduced to powder, even when the contents of the vessel was stirred twice a day. The same result was attained in less than half the time when a sulphate of lime was used, which was expressly prepared for the purpose by precipitation; this was owing to a more minute state of division of the particles of the sulphate, and, consequently, more ready solubility.

When burnt gypsum was used it became partly consolidated, and consequently of little effect, until again reduced to powder, when it acted effectually. When imperfectly powdered gypsum was used, only those portions underwent decomposition which were reduced to a fine powder, the outer portion of the coarse granular powder becoming coated with a crust of carbonate of lime, which totally prevented any further action of the ammonia on the gypsum inclosed within. Hence it is evident that unless gypsum be reduced to a very fine powder, it cannot undergo perfect decomposition, and also, that this action is greatly facilitated by frequently stirring the mixture.

As a proof that the decomposition of the gypsum has taken place, the following test may be applied:—Remove a portion of the precipitated powder, place it in a glass vessel, and pour over it vinegar or diluted muriatic acid as long as effervescence occurs; should a portion of powder remain undissolved, it will, in all probability, be undecomposed gypsum, but should the whole dissolve with effervescence, the decomposition of the gypsum has been complete. It would always be advisable to have a portion of undecomposed gypsum in the tank, ready to act on the ammonia as soon as generated, and to have the contents well stirred, at least twice a week.

In using sulphate of lime or gypsum in liquid manure, to convert the ammonia into a sulphate, for every 148 lbs. of (unburnt) gypsum, one cwt. of sulphate of ammonia will be formed; the same quantity will be obtained by the decomposition of 118 lbs. of burnt gypsum, or common plaster of Paris.*—*Alfred Clyde, Painswick.*

(To be continued).

* The urate of the London Manure Company is said to be gypsum heated to redness, and thrown into putrid urine, then removed, dried, and crushed.

Home Correspondence.

Fixation of Ammonia.—There is a slight mistake in the Notices to Correspondents of your Paper, June 15th, upon the subject of my experiments with sulphuric acid as a fixer of the ammonia in decomposing urine. According to my experiment, 16 gallons of putrid urine require for neutralisation 60¼ ounces by weight of sulphuric acid of sp. gr. 1.850. The quantity, however, will vary according to the strength of the acid, or the state of decomposition of the urine. I should prefer using diluted acid, in the proportion of 1 pound of acid to 6 or 8 of water, adding the solution until all effervescence ceases. The composition found to be of so much value by your correspondent "H. D.," of Witham, is strictly in accordance with chemical theory, or rather fact. "H. D." supplies to his plants all the elements of their composition. The crop being Turnips, the loss of the ammonia of the urine is not felt. If he were to fix his urine with dilute sulphuric acid, and then use it in the same way and apply it to Wheat or Beans, he will have excellent crops. In the way in which he has used the urine, it is probable no fresh combinations were entered into, or were necessary. Bones, charcoal, and urine contain everything, except silica, which the plant requires; and of this Turnips want little or none. Chemical Science will, in the end, attain its proper position in Agriculture. Practice may be, and is frequently wrong. Science may be applied incorrectly, but its truths are incontrovertible, and must be right.—*C. R. Bree, Stowmarket.*

Peat as a Top Dressing for Gravelly Soil.—In 1842 I planted a ten-acre field of this soil with Potatoes, and after the Potatoes were gathered in November, I gave a part of it a covering of about three inches deep of raw Moss, and over that again a slight sprinkling of land. Last year it was sown with Barley, and laid down with Clover and Rye-grass; the Barley was lodging in the part that got the covering of Moss, while the Barley in the other part of the field would hardly bend to the sickle at shearing time. This year the Hay is lodging where the Moss was put on, while in the other part of the field there is but a poor thin covering.—*A. C.*

Ox-eye Daisy.—Having observed a paragraph from "A Subscriber," requesting to be informed of a method of getting rid of the Ox-eye Daisy, I beg to state that in a field in my possession that had recently been laid down for permanent pasture, the Ox-eye Daisy sprung up in a part of it so thickly as to exclude other vegetation. The weed was mowed down when in flower, and the field was close fed by sheep for the ensuing year, when the Ox-eye Daisy entirely disappeared.—*A. C. L.*

Phenomenon.—In a field of Rye-grass and Red Clover now nearly fit for the scythe, we have observed more than once, at mid-day, a thin vapour arise on the windward side, and gradually spread over the whole surface, measuring 22 acres; and at the distance of half a mile, it appeared like the smoke of a large brick-kiln, and to parties near, quite a thin vapour. Now, the wind was light, and the day perfectly serene and beautiful. It travels along with the current of air, but there certainly was no appearance of disturbance in the air; and, what appears strange, it is confined to one field. The soil is a rich loam, and in a very dry state, having had no rain and but little dew for many weeks.—*W. D.*

[May this not be owing to the disturbance of the herbage by a gust of wind, which would raise, here and there, in the form of a vapour, the pollen of the ripe and dry Grass?]

Turnip-seed.—One man is born with a silver spoon in his mouth, another with a wooden ladle. Some of your happy correspondents, by soaking their Turnip-seed in Linseed-oil, and drying it in flowers of sulphur, have for years escaped the fly. I diligently soaked my Swede-seed this year in Linseed-oil for 48 hours, rubbing it repeatedly to impregnate every seed. I endeavoured to dry it with powdered sulphur, rubbing it diligently with more and more sulphur for five days together, until it was dry. I drilled it thick enough to please Mr. Morton, so that it comes up like Mustard and Cress; but the Turnip-flies seem as if they were a body of yeomanry called out this month, and they dress by the Turnip-rows exactly, and there is not a seed-leaf (such exact discipline do they keep) which is not perforated by them like a sieve, baffling the numerous instances in which they have eaten up the entire cotyledon. Wishing all other farmers better success in the experiment, I am, &c.—*W. P., Taunton.*

Mare and Foal.—Not seeing any answer in your Paper to your correspondent's question respecting a "mare and foal," I send the following:—Tie the mare up in a stable when the foal is to be admitted to her, and let a man stand behind her armed with a broomstick (a suitable broomstick—a switch or whip will not do), and when the mare offers to bite or kick the foal, let it be applied to the fleshy parts of the hind quarters. There is great virtue in a broomstick, but it all depends upon its being well applied, and with right good will. I have made a very savage mare take her foal in this way. Let your correspondent observe, I much prefer gentle measures, and only recommend the broomstick in extreme cases, where all such have failed. I have no doubt, though I never had occasion to try it, that a foal might be brought up on cow's milk from a bottle, as used by shepherds for lambs, till it was old enough to drink it from a pail, taking care not to give the milk too cold.—*D., an Old Dragoon.*

Bran.—In answer to H. Lawson's request, I beg to refer him to page 108 of Sir H. Davy's "Agricultural Chemistry," where the constituents of 100 parts of ashes of bran are said to be—

Soluble salts . . .	41.16
Earthy phosphates . .	46.5
Silica	.5
Metallic oxides . .	.25
Loss	8.59
	100.00

H. S., Bedhampton. [Another correspondent, "C. J." refers us to Dr. Ure's "Dictionary of Arts and Manufactures," under the word Bran. Saussure found bran to contain a large proportion of inorganic matter, almost identical with that of Wheat; viz., very rich in potash and the phosphates.]

Farmyard Manure.—It is now known to most farmers that, when cattle are full-grown, nearly all the mineral ingredients of the soil are returned with the droppings—the soluble salts in the urine and the insoluble with the solid excrements. Because we find certain mineral substances contained in all plants in definite proportions, we may conclude that these are absolutely necessary for their vigorous growth. It is, therefore, easy to understand how farmyard manure supplies the crops with food, as it contains it in the proportions required by them. Of what importance must it not be carefully to preserve this manure! In its natural state, however, it contains ingredients which, if left to themselves, are dissipated in the air, thus occasioning loss to the farmer. How are these ingredients to be preserved, and what are they? They are nitrogenous substances, that is to say, they contain that element—Nitrogen—which enters so largely into the composition of the plant, and serves to form the most nutritious portion of it. They are contained in two forms—as urea, and carbonate of ammonia. The urea, as soon, cannot serve as food to the plant, and is only of use when converted into a salt of ammonia. Now it so happens that such a change takes place when urine is left to itself; and a compound is formed—carbonate of ammonia—which can serve directly as nutriment. The only objection to it is its volatility; and we must endeavour to put it into an un

objectionable shape, so that it may easily be taken up and decomposed by the plant, without being volatile. This may be done in two ways—either by decomposing the carbonate of ammonia by means of a stronger acid, such as oil of vitriol (sulphuric acid), or spirits of salt (muriatic acid), and dispelling the carbonic acid, or by a double decomposition, whereby we fix both the ammonia and the carbonic acid. The latter is effected by sulphate of lime (gypsum), or muriate of lime, which decompose the carbonate of ammonia and form sulphate or muriate of ammonia and carbonate of lime (chalk). This decomposition only takes place when the agent (gypsum or muriate of lime) is dissolved in water; for which reason muriate of lime is preferable to gypsum, because it is soluble in its own weight of water, whilst the latter requires 350 parts of water to dissolve it. I presume, now, that all those farmers who read the *Agricultural Gazette* are acquainted with the value of the urine of cattle. Supposing the farmer has his tank, the best method of effectually preserving the ammonia of the urine, and of removing the smell from the stables and cowsheds, is to strew the floor, behind the cattle, with a sprinkling of gypsum every day. When this plan is first adopted, it is best to water the gypsum with a watering-pot, after having strewn it on the floor; as I have said that the action of it on the carbonate of ammonia does not take place till it is dissolved. If the farmer wishes to remove the smell from his stables, he will be obliged to wash the walls with a solution of gypsum, or better, with a solution of muriate of lime, and afterwards with pure water, for the walls in an ill-ventilated stable are covered with a solution of ammonia in water. In preparing the farmyard heap, it should be a rule with the farmer to heap it on as small a space and as compact as possible. The ground on which it is to lie should either be bricked or should consist of a very stiff clay, and should be about half a foot below the surrounding ground, and should be situated at the lowest part of the farmyard. By means of pipes the floor is connected with the tank, so that all the urine and water may run off. A layer of gypsum is now to be spread on the flooring, and the heap is to be commenced by covering the whole bottom, with the exception of about half a foot on every side. On every foot-height of manure a layer of gypsum is to be spread, sufficiently thick to appear white. When the heap is completed, or before, the contents of the tank are to be poured on by degrees, in quantity sufficient to wet the heap well, but so that not much will run back into the tank. By these means the following advantages will be obtained:—1st. The cartage of it in water-carts will be rendered unnecessary, and some labour saved. 2d. The gypsum of the farmyard heap will be dissolved; and, 3d, by the addition and evaporation of the water of the urine, the decay of the farmyard manure will be facilitated. To the question, How should farmyard manure be applied? I answer: If the soils are light, the farm-yard manure cannot be too much decayed, provided proper precautions be taken to preserve all its useful ingredients by the means already stated. The farmer will, in this case, do well only to place as much on his land as will suffice for the nutriment of one crop, because a large portion of it will be washed beyond the reach of the roots of the plants by the falling rains. If the soils are heavy, it will be better to plough your farm-yard manure under, in as recent a state as possible, again providing it has been properly preserved; the fermentation of the Straw may tend to lighten the soil in such a case. If the manure is to serve immediately as food to the plant, it must be decayed; if, on the contrary, it is to act slowly, it should be fresh; as to the time when it should be placed on land, farmers are much at variance. For pastures it should be spread after the first mowing of the Grass—if possible on a rainy day—and should be as much decayed as possible. It will then act as quickly as guano. For arable land it will much depend upon the state of the soil and upon the nature of the crops. I may, however, be allowed to add, that it is a downright absurdity to lead out unprepared farm-yard manure on a hot day, and to leave it for any length of time in heaps on the soil. This I have seen scores of times; the loss which takes place is nigh incalculable. We have hitherto spoken of pure farm-yard manure; we must now make some remarks on the farm-yard manure of most agriculturists. It is a common practice to collect the weeds of the soil and to spread them on the dungheap. Farmers seem not to be aware that whilst they destroy one individual plant they may sow again at least a hundred, if the weeds are in seed. Now this is frequently the case, although many say that seeds are killed on the dunghill. This idea is fallacious; some seeds may be killed, but most are not. Many wonder at the numberless weeds that constantly reappear on fields that have been carefully weeded, and yet they seek not the cause so near home, forgetting that they sow the seeds themselves. I have known farmers who allowed that seeds were not killed on the dunghill, and resorted to the worse system of adding lime to the dunghill. It is true that the seeds were killed, but at the expense of the ammonia and the organic matter. Far better mix the weeds with caustic lime, to burn them, which amounts to the same. Another practice is to place the Potato stalks on the dunghill, without any precaution as to whether they are again conveyed to the field they grew upon or not. This is not immaterial when the farmer recollects that these stalks contain a most necessary ingredient of the stalks of grain. It is owing to the frequent removal of these stalks that land is so very impoverished, inasmuch as the haulm of grain are scarcely able to support themselves. If these stalks are placed on the dungbill, it is necessary to use that part of the heap on which they have been put, as manure for the land from which they have been taken. I have only one remark more to make, which appears to be of great importance. I have known gentlemen who have bought up the manure collected by poor people, and who have manured meadows with it. The consequence has been, in two cases which have come under my more immediate notice, that the Grass has almost been totally extirpated by numerous weeds. They were not able to give any reason for this change, but only told me whence they had bought their manure. It was chiefly the manure of horses, which had been fed on the highroads, or on weeds collected from different parts. The weeds must have been in seed, and have passed unchanged through the stomach of the horse, germinated, and sprung up in the soil. There can scarcely be a farmer who has not, on some occasions, found a few solitary grains of corn growing in the dung of horses. Having seen this myself, I endeavoured to find out whether small seeds were killed by passing through the body of a horse. For this purpose I fed an old horse with weeds in seed, collected its dung, and mixed it with soil in which I believe there were no seeds of any kind. The box which I filled with this mixture was, after eight days, filled with weeds, which, after the lapse of a few weeks, I was able to recognise as the same species as those on which the animal had been fed. Here, then, I found a key to the mystery. This must be the case constantly in a weak horse and in an old horse. It is not without good grounds that sheep are said to improve pasture lands, as the process of digestion in them seems to be more powerful and complete than in horses, at least old ones. May it not be the case with most old animals? I conclude with this, and merely add that I should be glad to hear of any communication to this effect.—*Albert J. Bernays.*

Drainage.—Would you have the kindness to inform me whether charred branches of trees can be advantageously employed, as well as drain-pipes, in draining heavy land? My hedge-rows would furnish me with an abundance of loppings fit for charring, and I should be glad to so employ them. As charcoal is almost impenetrable, I should think this might answer, at least for a good many years.—*Thomas Holmes.* [Your suggestion is, we think, new; loppings of trees and hedges have long been employed as material for filling drains, which, so filled, act efficiently, though not permanently. If they were charred superficially (not thoroughly, lest, being brittle, they should break into small fragments when being placed in the drain), they would be equally suitable for this purpose, and they would have, in addition, the important character of permanence conferred upon them.]

Rooks.—That the food of this bird is various in its nature I know from undeniable facts; early in this spring I had two rooks brought to me that had been killed on a field of spring Wheat, and the craws contained Wheat only, with the usual accompaniment of gravel; but it is the Potato crop that suffers most in this country. That the rook is also of great use to the farmer must, I think, also be true, as he is constantly seen on fresh ploughed land, and often on Grass fields, where only insects can be met with. The balance of good or injury that the bird does can only be estimated by conjecture, without a close examination into the birds' usual habits. But I am inclined to think, notwithstanding the injury done to the Potato crop—notwithstanding these birds being gramivorous must consume very much Corn—yet, that if their food was not more abundantly composed of insects, that from their immense numbers, the crops both of Corn and Potatoes would be totally destroyed, instead of partially injured.—Δ. [This is, we think, the fair conclusion to be derived from this discussion, which, in the absence of any fresh facts on the subject, we must now bring to a close.]

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND

At a weekly Council held at the Society's house in Hanover-square on Wednesday last, the 10th of July, present, His Grace the Duke of Richmond, K.G., in the chair, Lord Bridport, Hon. George Agar, Hon. Geo. H. Cavendish, M.P., R. Archbold, Esq., M.P., C. H. Baldock, Esq., D. Barclay, Esq., M.P., T. R. Barker, Esq., J. R. Barker, Esq., J. Benett, Esq., M.P., H. Blackett, Esq., W. R. Browne, Esq., F. Burke, Esq., Dr. Calvert, Rev. Thos. Cator, Col. Challoner, F. C. Cherry, Esq., L. Cooke, Esq., G. Cottam, Esq., J. Dean, Esq. J. E. Denison, Esq., M.P., R. Etwall, Esq., M.P., H. Gibbs, Esq., J. B. Glegg, Esq., Col. Henderson (Mayor of Southampton), E. Holland, Esq., Sir John V. B. Johnstone, Bart., M.P., T. Jones, Esq., J. Kinder, Esq., J. Marmont, Esq., Col. MacDouall, E. Parkins, Esq., E. W. W. Pendarves, Esq., M.P., E. S. C. Pole, Esq., H. Price, Esq., J. Roddam, Esq., J. Scales, Esq., Prof. Sewell, J. V. Shelley, Esq., R. A. Slaney, Esq., T. H. B. Sotheron, Esq., M.P., W. B. Stopford, Esq., and T. Tweed, Esq., the following new Members were elected:—

Quicke, Rev. Andrew, Winchester.
Withers, Rev. Edward, Phillimore Place, Kensington.
Bull, Alban, Hanwell, Banbury, Oxon.
Vivian, Lord, Glynn, Lostwithiel, Cornwall.
Bourne, Henry Titus, Alford, Lincolnshire.
Templemore, Lord, Dunroby Park, Co. Wexford, Ireland.
Sewell, Robt. Burleigh, Newport, Isle of Wight.
Dickinson, Edmund Henry, Kingweston, Somersetshire.
Henderson, Richard Langley Ford, Wooler, Northumberland.
Reed, Thos., Warkeworth Barns, Alnwick, Northumberland.
Pink, Richard, Hambledon, Horndean, Hants.
Pink, Charles, Hambledon, Horndean, Hants.
Winnington, Sir Thomas, Bart., Stanford Court, Worcester.
Chapman, Thos. Sands, Aston Clinton, Tring, Herts.
Pain, George, Salisbury.
James, Charles, Stratford, Salisbury.
Aitchison, Capt R., Bartley Manor House, Eling, Southampton.
Bird, J. A. Park Cottage, Brixton, Surrey.

The names of twenty-three candidates for election at the next meeting were then read.

PIPE-TILE MACHINE. — Mr. Cottam, of Winsley Street, Oxford Street, favoured the Council with a report on the latest improvements effected in the Benenden Machine of Mr. Hatcher for the production of cylindric draining tiles. This machine in its present state consists of a framework supported on wheels: one-third of its length being appropriated to the platform of the machine for the manufacture of the tiles, and the remainder to the apparatus of the endless web for supporting the pipes as they are formed, and conveying them to the hands of the boys stationed to receive them. On a level with this endless web, and between two upright posts, is placed a square iron box, which forms the bottom of the machine. It is open at the top and at that side in its front which adjoins the endless web. This box is always full of clay, the iron grating which acts the part of a sieve or screener of the clay being placed on the top of the box, and the required dies, or plates of iron, with apertures for the shape of tile required, secured in front. On this box thus arranged, is placed a cylinder filled with clay from the pug-mill, and the piston being inserted, and forced down steadily by means of a winch working a couple of toothed wheels, the clay is driven under great pressure through the iron grating into the square box, and thence out of the box, through the apertures which constitute the pattern-dies of the tiles, which, as they issue continuously from the machine, are conveyed along the endless web set in simultaneous motion with the piston by a connection with the same winch and a couple of rollers. As one cylinder becomes emptied another is ready to replace it. A boy is stationed at each side of the endless web, and measures off the tiles, piling them alongside the machine, which as the work proceeds is moved from time to time forward, out of the way, by means of the wheels on which it is supported. Mr. Cottam explained to the Council the various improvements effected in the action of the piston, the insertion of the die-plates, the material best adapted for the endless web, and the mode adopted for keeping it in proper tension, the apparatus for measuring and cutting off the tiles, the advantages possessed by the cylindric shape of the tiles for arranging them, both for the purpose of drying and burning equably, the rate of charge for labour, fuel, &c., the number of tiles produced per day, &c. &c. He submitted to the inspection of the Council a model of the machine, and one of the cutters for measuring off the tiles. This apparatus Mr. Cottam described as one of the most ingenious and efficient contrivances he had ever met with for accomplishing its purpose by the most simple means. Previously to its use, the tiles were cut off by a wire without measurement; the consequence of which was, that they were not only of unequal length, but injured by the pressure of the hands on their sides on being conveyed away from the machine. It consists of a wooden roller, secured firmly by a screw at one end to a plate of iron; to this iron plate an iron bar is secured, which runs parallel three or four inches above the roller, and serves the purpose of a handle for the boy, as well as a support for the cutting-wire, which moves in a frame and socket up and down in front of the roller. The boy takes the apparatus by the handle, and inserts the roller inside the pipe-tiling up to its hilt at the iron plate; he then draws the cutting-wire, when the pipe-tile is perfectly severed, and remains loose on the roller, from which he at once allows it to glide off into its proper place, without injury or loss of time. Mr. Cottam stated that the cost of the machine complete would be 25*l.*; and for the inspection of such members of the Society as felt an interest in the subject, he had made arrangements at his manufactory in Winsley-street (opposite the Pantheon, in Oxford-street), to have the machine at work daily from 12 to 3 o'clock. Assuming one man, one youth, and two boys to be employed at the machine (including pug work), with one man at the kiln, and the price of coals to be 25*s.* per ton, the following results would be obtained by calculation from the data laid by Mr. Cottam before the Council on this occasion:—

Diameter of Tiles.	Number that can be made in a day of 10 hours.	Cost per Thousand.
1 inch.	11,000	4*s.* 6*d.*
1¼ inch.	8,000	5*s.* 6*d.*
1½ inch.	5,800	6*s.* 0*d.*
2 inches.	4,000	7*s.* 3*d.*
2½ inches.	3,200	8*s.* 6*d.*

Mr. Denison, M.P., remarked that when it was taken into consideration how many points there were in the new system of tile-making which this machine would affect in reference to the cost of production, it could not be doubted that in the progress of the experience to be gained it would be found, that in the less amount of clay required, the consequent reduction in fuel for burning, and the local advantage of coals to be obtained in so many parts of the kingdom at a less rate than that of 25*s*, as assumed in the present inquiry, there would be every reason to believe that tiles might be made by means of this machine at a still lower cost even than that which was at present deducible from the facts laid before the Council.

Mr. Denison then proceeded to give the Council an interesting narrative of the history of the ingenious inventor of the present tile-machine; and as he had liberally given up (at the patriotic suggestion of his patron, Mr. Law Hodges) all patent right in reference to its manufacture—a privilege probably equivalent to a premium of no

less than 3000*l.*—he trusted that all members of the Society who intended to purchase the machine would obtain it at head-quarters, of the inventor's accredited agents, Messrs. Cottam and Hallen, both in reference to his own peculiar claims on the consideration of the promoters of agricultural improvement, and to the desirableness that no parties should experience disappointment by the purchase and employment of an inferior machine: he thought such a choice in their selection would not only be fair to the inventor, but a slight return to him in remuneration for the benefits he will have conferred on those persons who are so unfortunate as to have land which requires draining.

The Duke of Richmond then proposed the best thanks of the Council to be given to Mr. Cottam for his kindness in explaining to the members the construction of this machine; which were carried unanimously.

Southampton Meeting.—The Mayor of Southampton has communicated to the Society the rates at which it has been determined to limit the prices for lodgings at Southampton during the ensuing meeting: on which occasion no beds would be charged more than half-a-guinea per night under any circumstances, while others would range at prices considerably lower according to situation and condition. Every facility would be given to promote the comfort of the numerous visitors expected on that occasion.

(To be continued.)

HIGHLAND AND AGRICULTURAL SOCIETY.

The half-yearly meeting was held on Tuesday last; the Earl of Leven in the chair. After electing 110 new members, the secretary gave in the Report on the premiums offered by the Directors for this year from the funds left to their disposal by the general meeting in January. Among the new premiums, 100*l.* is offered for experiments with special manures, separately, or mixed in certain proportions, and on the effect of such manures on the succeeding crops of the rotation; for reports of experiments on various descriptions of food—as Carrot, Beet, Potatoes, Beans, Oats, Barley, and Oil-cake, afforded to grazing and fattening stock and to dairy cows—50*l.* for an analytical examination of the grain of Oat, as affected or modified by soil, manure, climate, or variety of seed, intended as a commencement of a series of premiums for analyses of the cultivated grains of the country; 50*l.* for an illustration, by chemical analysis, of sound and healthy plants of different varieties of the Potato, of the cause of the disease which has of late years affected that valuable root.—Sir John Hope reported on the Veterinary College, which he said had been most successful, and, as a proof, in last April, 41 students had qualified and passed their examinations. Besides those in Scotland many students had come from different parts of England and Ireland. The Professor had lately told him that since the commencement of the College upwards of 700 students had attended his lectures.—Sir John Graham Dalyell reported from the committee on machinery, that at their last meeting they had awarded three medals—two silver medals for improvements in the internal economy of farm-yards, and a gold medal to Lord James Hay, for the great trouble and expense incurred by him in devising the manufacture of his concrete drain tiles, and laying the plan before the Society.—Mr. Miller, Forrest, moved that the Society should use its influence to have the markets for grain throughout the country reported in a uniform manner; almost every market at present reported their sales by different measures, which rendered it a matter of extreme difficulty to strike an average among them.—Thanks were voted to the Earl of Leven and Melville; after which the meeting adjourned.—*Edinburgh Paper.*

AGRICULTURAL CHEMISTRY ASSOCIATION.

The usual half-yearly general meeting of the subscribers to the Agricultural Chemistry Association was held on Monday in the Museum of the Highland and Agricultural Society: Lord Dunfermline in the chair. The Secretary, Mr. Coventry, read the half-yearly Report, extracts from which we shall publish next week.

CIRENCESTER AGRICULTURAL COLLEGE.

On Monday last a meeting of those interested in this institution was held at Cirencester, Earl Bathurst in the chair, to report the progress of the committee in the establishment of the College. The Report will be found in another column, and will be read with lively satisfaction by the friends of the undertaking. The Society has now resolved itself into a tangible shape, and will immediately commence operations. Port Farm, within one mile of Cirencester, the property of the Right Hon. Earl Bathurst, and in the present occupation of Mr. Stevens, has been fixed upon as the site for the example farm. Mr. Sotheron, in proposing the first resolution, observed, that about six months ago he first heard of this college, and he then thought it of so speculative a nature that it would never have been carried into effect. He had, however, been now entirely brought to the opinion that it was likely to be practically useful to all classes of agriculturists. The main point in this undertaking was to obtain a good system of management by gentlemen who would not go through their duties in a hurried manner, but would allow no detail to be carried out without their sanction, by rules and meetings. He had ventured to make these remarks, as he had lately taken some part in the formation of an institution, which resembled the present in many respects—the Marlborough Proprietary College. He had there seen what errors they might have fallen into during the last years, had they not had a gentleman to conduct it who was well conversant with his duties, and by whose exertions they had been enabled to keep their expenditure within the limits of their income. This had convinced him of the necessity of a good system, which could only be achieved by placing men of business at the head of their affairs.—Mr. A. Fewster, in moving the fourth resolution, said that it would hardly have been deemed possible that any person could have been found to oppose so desirable an object as this, though experience proved the contrary. One objection he had heard was that it would train up young persons to be sort of dandy farmers, whom landlords would not be very much inclined to have as tenants, and indeed if they did, they would get no rent out of them. Another thought the establishment of this college a dangerous matter, as tradesmen's sons and other young persons would be so well instructed as to drive "us old codgers out of the market." These two objections he thought entirely destroyed each other. It was preposterous to believe that a person should be unable to cultivate the soil because his mind was cultivated. He was acquainted with the projectors of this college, and knew their object to be to establish, not a theoretical institution, but one based on a sound practical foundation. He gave agriculturists credit, as a class, for being fully as industrious as any class of the community, though at the same time he must own there was a great lack of intelligence amongst them. And why should not agriculturists receive as good education as any other class of the community? It would be productive of advantage to the higher classes, because the landlord would reap the benefit of a skilful application of a larger amount of capital on his land. The farmer, however, will be a greater gainer still by the college—it would be the means of imparting a purer and more healthy tone of moral feeling amongst his children. It was gratifying to notice what a change had taken place in this respect since he had first attended market, a period of 30 years. Formerly the conversation at the market ordinaries was calculated to produce anything but a good effect in the minds of those who partook in it. At present, however, the conversation turns on the improvement of stock, and the better cultivation of their farms, to advance which latter object was the intent of this Society. Farmers would thereby be brought into more immediate contact than they generally are, and would be enabled to combine science with practice. The moral advantages, too, would not be confined to this class alone, but would also extend to the industrious labouring classes. The improvements in the cultivation of the farms produced by this College, with the means resulting therefrom, would be such that there would be a very large increase in the number of labourers employed in the cultivation of the soil at the present time; and what effect would this produce on the manufacturers and the home market!

FARMERS' CLUBS.

Debenham.—The subject of discussion on June 28th, 1844, was the Drainage of Arable Pasture Lands. The member who introduced it said he would merely state to the Club the manner in which he drained his farm, which has a flat surface, and a subsoil which he might call a clay, only he could not dig a rod without either meeting with a vein of sand or gravel. He preferred drawing the drains obliquely instead of in the direction of the furrows. He found eight or nine yards from drain to drain sufficiently close; he opened the drains with the plough as deep as possible, then followed with the broad and draining spades, to the depth of 22 inches; he thought ling the best material to put in the drain, but on account of its distance he is obliged to use straw, haulm, bushes, &c. Where straw is used he would put it into the drain loose, not twisted; he would, of course prefer tiles, but they ought to be found by the landlord. For pasture land he had tried the mole or draining-plough, but on his description of land he found it perfectly useless. He had also ploughed out a deep furrow with the common plough, and then used the narrow or draining-spade only; this he did not approve of; he thought it best to pursue the same plan for pasture as he did for arable land, excepting that he made his drains at distances of 11 yards, which laid his pastures sufficiently dry.—Another member said he considered draining in this district of the greatest importance; it was almost useless to manure the land unless it was first thoroughly and efficiently drained. He occupies a farm with a very stiff subsoil, and therefore opens his drains only six yards apart; he also prefers his drains in an oblique direction, instead of following the track of the ridges; thinks the drain cannot well be made too deep; it ought not to be of less depth than 32 or 34 inches. He has purchased Furze for filling in the drains; finds four score faggots sufficient for one acre, costing on the heath 2*s.* per score. He has also used the plashings of borders, ditches, &c., for filling in the drains; considers there are several objects gained by so doing;—First, employ is found for an extra labourer, straw or haulm, which would otherwise be used, is saved for manure, and the borders, banks, &c., are freed from Brambles, rubbish, &c. He is of opinion that great attention should be paid to the filling in of the earth turned out of the drain; the clay drawn by the narrow or draining-spade should be carefully placed upon the shoulders and well stamped down before the other mould is put into the drain; he lays a pipe about 12 inches long, and compressed at one end, in the eye of each drain, to keep out rats, rabbits, &c. His pastures having also a strong subsoil, he has drained the greater part at distances of five yards, and one piece which immediately abuts upon his homestead, every four yards, with the mole or draining-plough, at a depth of 24 inches.—A third member, whose farm was different from the two preceding members', his land being much more hilly, the subsoil on the hills being very stiff, while towards the bottom it was much lighter, thinks five yards apart quite sufficient on strong lands; thinks Hag better than Furze; next to draining-tiles would use picked stones, could sufficient be obtained; drains ought to be 32 inches deep; draws his drains obliquely across the slope of the lands. For pasture land, if drained by hand, thinks nine yards from drain to drain sufficiently near.—It was ultimately resolved, that in draining arable land the spade is decidedly preferable to the mole-plough; that the nature of the subsoil must determine the distance between the drains; that while on stiff or strong clay lands five to six yards may be a sufficient distance, on loose-bottomed *gaulty* soils there may be a distance of seven or eight yards from drain to drain; that 30 or 32 inches is the proper depth for a drain. Tile-draining is most desirable on tender or springy soils, but it being a permanent improvement the tiles should be furnished by the landlord. That the mole or draining-plough is the best for pasture land.—*W. G., Hon. Sec.*

Reviews.

The History, Structure, Economy, and Diseases of the Sheep. By W. C. Spooner, V. S., &c. Cradock and Co., 48, Paternoster Row. 8vo. Pp. 456.

[Our readers will recognise this title, as that of a volume from which we have already been permitted to make several instructive extracts. See pp. 329, 416, *Ag. Gazette.*]

"This work is divided into three Parts. The first, which embraces the history or description of the breeds of sheep, is arranged somewhat according to the plan adopted by Professor Low in his large work on the Breeds of Cattle and Sheep; and the author has availed himself of this work in the account of the various races of sheep found in the northern part of the Island; whilst he has relied principally on his own knowledge for the description of the more southern breeds. The most important portion of the anatomical division of the work has been the result of careful dissection; and for the section on Feeding, Fatting, and Breeding, the author alone is responsible. In the third Part, on the Diseases of Sheep, free use has been made of the various papers contributed to the 'Veterinarian,' &c."

The above, extracted from its Preface, is accurately descriptive of this work. The name of Mr. Spooner, who is a distinguished member of his profession, is a sufficient guarantee for the accuracy and usefulness of its contents. Let us extract from the chapters on Feeding and Fatting, which he informs us are more particularly his own, the following, as a specimen of the style in which this section of the work has been executed:—

"The various points in the form of a sheep, connected with the aptitude to fatten, have received the utmost attention from practical and sagacious breeders, although some of these points are still matters of dispute. The superiority of particular improved breeds is now generally acknowledged, and may indeed be considered to be established on certain principles, though in arriving at these principles it must be confessed that we are little indebted to science, but to the long and attentive observation and correct reasoning of sagacious and practical men. It is, indeed, only very lately that anything like a correct explanation could be offered for the various phenomena that attend the fattening of animals, or why one description of food should be more suitable for the purpose than another. It had, indeed, been laid down as a fact, that a large capacious chest and lungs were necessary for the production of fat, and that its secretion depended in a great degree on the quantity of air that could be respired; whilst the researches of modern chemists have shown that nothing could be further from the truth. And now that the fallacy has been exposed by chemistry it can also be readily shown by anatomy, for we find that whilst the horse and the camel have eighteen ribs, the ox and the sheep have only thirteen. The absence of these five pair of ribs must of course materially diminish the cavity of the chest, and its greater breadth (necessary for another purpose) does not by any means compensate for its diminished length. Animals of speed have rarely a propensity to fatten, but in greyhounds, hares, foxes, deer, &c. we find the chest is long and deep, though not wide, whilst in pigs, sheep, and oxen we notice an opposite conformation. The fact is, in proportion to the activity of the animal is its respiration and its demand for oxygen, and in proportion to the consumption of oxygen is the wear and tear of the system and the consumption of the elements of the food. If the exertions are therefore excessive, that portion of the food that would have increased the weight of the body is called for to support respiration.

"In animals having a propensity to fatten, we find the chest of a circular form; the ribs spring from the spine more horizontally than in others, almost at right angles: this is observed in the ox, compared with the horse, and still more so in the sheep. The effect of this conformation is certainly in one respect to increase the width of the chest, but another important effect is to increase very considerably the size of the abdomen; for in order to obtain the greatest possible nutriment from the food, it is essential that the organs of digestion should be capacious, which cannot be the case unless the cavity in which they are situated is large."

This is a book which Farmers' Clubs ought to add to their libraries, and as a work of reference, it ought to be in the possession of all sheep-farmers. The first Part contains a great deal of very interesting reading, and, as as well as the second and third Parts, which are likely to form the more *useful* portion of the volume, it is illustrated by good engravings.

Lectures on Agricultural Chemistry and Geology. By James F. W. Johnston, M.A., F.R.SS. L. & E. Reader in Chemistry and Mineralogy in the University of Durham, &c. William Blackwood and Sons, Edinburgh.

To enable one to write usefully on the subject of these Lectures, it is evident that the most intimate knowledge of chemical or geological science is not all that is necessary; an acquaintance with the practical details of farming is required by any one who would apply the doctrines of chemistry to the improvement of agriculture; and Professor Johnston, in his capacity of Chemist to the Agricultural Chemistry Association of Scotland, has enjoyed opportunities of becoming acquainted with correct agricultural management, better than perhaps ever before fell to the lot of any scientific man. The consequence is, that while his writings will doubtless for a long time to come be an authoritative standard to which all questions about the bearings of chemistry on agriculture will be referred, both they and his Lectures have a practical and most useful tendency.

In Scotland the efforts of Professor Johnston during the past year, in diffusing a knowledge of the relations of chemical science to the practice of the farmer, have been extraordinarily successful. Some of the immediate results of his agency on behalf of the Agricultural Chemistry Association will be found in the Report in another column, of the late half-yearly meeting of that Society; but perhaps as much benefit will ultimately arise from the spirit which he has aroused in agricultural districts, by which the connexion of science and farming being duly appreciated, a desire for scientific information has been excited. The existence of this desire is proved by the establishment of no fewer than seven or eight agricultural periodicals in Scotland within the last year.

We mention all these as the effects of Professor Johnston's teaching in Scotland, to show the value to agriculture generally, of a systematic work on Agricultural Chemistry and Geology, by one so thoroughly qualified to write on these subjects. But we must also select for this purpose some extracts from these Lectures.

The following remarks are on the action of lime as manure:—

"The changes, therefore, which lime and organic matter, supposed to be free from nitrogen, respectively undergo, and their mutual action in the soil, may be summed up as follows:—

"1. The organic matter, under the influence of air and moisture, spontaneously decomposes, and besides carbonic acid which escapes, forms also other acid substances which linger in the soil.

"2. With these acids the quick-lime combines, and either by its union with them or with carbonic acid from the air, soon (comparatively) loses its caustic state.

"3. The production of acid substances by the oxidation of the organic matter goes on more rapidly under the disposing influence of the lime, whether caustic or carbonated. These acids combine with the lime, liberating from it, when in the state of carbonate, a slow but constant current of carbonic acid, upon which plants at least partly live.

"4. The organic acid matter which thus unites with the lime continues itself to be acted upon by the air and water, aided by heat and light—itself passes through a succession of stages of decomposition, at each of which it gives off water or carbonic acid, retaining still its hold of the lime, till at last, being wholly decomposed, it leaves the lime again in the state of carbonate ready to begin anew the same round of change.

"During this series of progressive decompositions, certain more soluble compounds of lime are formed, by which plants are in part at least supplied with this earth, and which with the aid of the rains carry off both lime and organic matter from the soil. And again, the more rapid the production of the acid substances which result from the union of the organic matter with oxygen, the more abundant in general also the production of those gaseous and volatile compounds which they form by uniting with hydrogen, so that, in promoting the formation of the one class of bodies, lime also favours the evolution of the other in greater abundance, and thus in a double measure contributes to the exhaustion of the soil.

"The disposing action of lime to this twin form of decomposition few varieties of organic matter can resist, and hence arises the well-known efficacy of lime in resolving and rendering useful the apparently inert vegetable substances that not unfrequently exist in the soil.

"*Of the Comparative Utility of Burned and Unburned Lime.*—Is there no advantage, then, you may ask, in using caustic or burned rather than carbonate or unburned lime? If the ultimate effects of both upon the land be the same, why be at the expense of burning? Among other benefits may be enumerated the following:—

"1. By burning and slaking, the lime is reduced to the state of an impalpable powder, finer than could be obtained by any available method of crushing. It can in consequence be diffused more uniformly through the soil, and hence a smaller quantity will produce an equal effect. This minute state of division also promotes in a wonderful degree the chemical action of the lime. In all cases chemical action takes place between exceedingly minute particles of matter, and among solid substances the more rapidly, the finer the powder to which they can be reduced. Thus a mass of iron or lead slowly rusts or tarnishes in the air; but if the mass of either metal be reduced to the state of an impalpable powder—which can be done by certain chemical means—it will take fire when simply exposed to the air at the ordinary temperature, and will burn till it is entirely converted into oxide. By mere mechanical division the apparent action of the oxygen of the air upon metals is augmented and hastened in this extraordinary degree, and a similar result follows when lime in an impalpable state is brought into contact with the vegetable matter upon which it is intended to act.

"2. The effect of burned lime is more powerful and more immediate than that of unburned lime in the form of chalk, marl, or shell sand. Hence it sooner neutralises the acids which exist in the soil, and sooner causes that decomposition of vegetable matter of every kind to commence, upon which its efficacy, in a great degree, depends. Hence, when it can easily be procured, it is better fitted for sour Grass or arable lands, for such as contain an excess of vegetable matter, and especially for such as abound in that dead or inert form of organic matter which requires a stronger stimulus—the presence of more powerful chemical affinities, that is—to bring it into active decomposition. In such cases, the lime has already done much good before it has been brought into the mild state, and remaining afterwards in this state in the soil, it still serves, in a great measure, the same slower after-purposes, as the original addition of carbonate would have done.

"3. Besides, if any portion of it, after the lapse of two or three years, still linger in the caustic state it will continue to provoke more rapid changes among the organic substances in the soil, than mild lime alone could have done.

"4. Further, quick-lime is soluble in water, and hence every shower that falls and sinks into the soil carries with it a portion of lime, so long as any of it remains in the caustic state. It thus reaches acid matters that lie beneath the surface, and alters and ameliorates even the subsoil itself.

"5. It is not a small additional recommendation of quick-lime, that by burning it loses about 44 per cent. of its weight, thus enabling nearly twice the quantity to be conveyed from place to place at the same cost of transport. This not only causes a direct saving of money—as when the burned chalk of Antrim is carried by sea to the Ayrshire coasts—but an additional saving of labour also upon the farm, where the number of hands and horses is often barely sufficient for the necessary work."

The remark in the last paragraph of this extract from Prof. Johnston's Lectures, demonstrates that attention to the practical bearings of his subject, of which we have been speaking, no less than the other portions of it evidence his scientific ability. We shall return more than once to the consideration of selections from this work, which must for many years be a text-book on the subjects of which it treats.

Miscellaneous.

Statistics of Tile-draining in Ayrshire.—Tile draining as a system was commenced in this county about twenty years ago. At that period a great many farmers were very averse to it; so much so, that otherwise intelligent men would not consent to give it a fair trial. One great objection regarded the durability of the tile, and the improbability of the water getting down to the drain; all hesitation on these scores, if properly manufactured and judiciously laid, have been completely set aside: and to show how thoroughly the agricultural interest have become persuaded of the immense advantage of the system, it need only be stated that, there are beyond fifty Tile-works in Ayrshire alone! These will produce on an average thirty millions of tiles yearly—a quantity capable of draining not less than 12,396 imperial acres, allowing a distance of eighteen feet between the drains, and the tiles one foot long. The number of acres in Ayrshire is 793,600, and suppose one fourth to be incapable of amelioration, there will still remain 595,200 of improvable land. At the present rate of tile-making, taking it for granted that the whole will be used, and deducting 150 millions as the manufacture of previous years, it would require nearly 43 years to complete the drainage of the county. The price of thirty millions of tiles, at 25*s.* per 1000, would be 37,500*l.* The quantity of coal consumed will be about 15,000 tons, and the number of men and boys employed in making them not less than 1200. Thirty millions of tiles, one foot in length, will lay 1,621,621 falls of drains, 18½ feet to the fall, or nearly 6000 miles. Supposing the average cost of cutting, laying, and filling the drains to be 4*d.* per fall, the total would amount to 27,027*l.*, and calculating a labourer's wages at 10*s.* per week, for sixteen weeks in the year, the usual period of draining in this county, it follows that employment is given to 3378 men—a matter of no small moment, especially at a season when other out-door work is not to be had. Granting that 150,000,000 of tiles have been laid prior to this date, 61,980 imperial acres will necessarily have been drained. Take the produce before the land is subjected to this process at six bolls, and now at ten, per acre—a medium average—the increase over former years will be 247,920 bolls, or 123,960 quarters. Carrying the calculation a little farther, suppose that equal enterprise is displayed during the next ten years—and there is every probability that it will far exceed it, should no political shock affect the encouragement of home agriculture—the stimulus given to the productive capabilities of the soil will be still more strikingly apparent. Ten years' draining at 12,396 acres yearly, will give a total of 123,960, or an increase at the previous average of 247,920 quarters of grain, thus showing an augmentation in the means of existence of 66 per cent., while it is well known that the gross increase of the population in any previous period of ten years has not much exceeded 15 per cent. The above calculation of produce, &c., is of course limited to the county of Ayr; and, great as the benefits are which it exhibits, how much greater would they be in a national point of view were the naturally rich lands of England and Ireland subjected to a similar process!—*R. Boyle, Esq., in Ayrshire Agriculturist.*

Laughable Mistake.—A carrier, in the neighbourhood of Bolton, recently had to convey a barrel of Roman cement to a gentleman, and a barrel of guano to a farmer, each of which he delivered to the wrong party. A plasterer commenced preparing the guano, which was given to him as Roman cement; and, after much difficulty, owing to the bad smell, he succeeded in plastering a few yards of the gentleman's house; but, the stench becoming past his endurance, he called out to the gentleman, and said, "I am very sorry, but I must beg of you to get some other person to finish this job, for I never met with such Roman cement before. I am quite sick, and the smell will poison me if I go on; besides, did you ever see Roman cement so yellow?" The gentleman said there must be some mistake, for it evidently was not cement, and accompanied the plasterer to the carrier's, where they found the farmer complaining about the barrel of stuff he had got. It was like sand; but when mixed with water it turned into stone, and would flag his field instead of making the Grass grow almost as quick as winking, as he was told this new manure would do. His man had mixed water with some of it, and spread it out; and, on returning a short time afterwards, he found the stuff as hard as a flag, and came to him in breathless haste, saying, "Mestur, I nevvur seed sitch stuff I aw my loife as yon, for I mixt sum on't wi weytur, un its turned into a flag."—"O!" exclaimed the plasterer, "that must be the Roman cement, and I have been mixing up your guano instead of it."—*Bolton Free Press.*

Notices to Correspondents.

ADHESIVE LAND.—*Villager.*—You may safely use the sand, of which you sent a specimen, in the manner you propose. With respect to your light land, pond mud and clay, previously mixed with lime, are likely to be beneficial applications.

ALPACA.—*E. R.*—Thanks for your correction; the passage was quoted from another paper. The ordinary route from Peru is, of course, round Cape Horn.

BRAN.—*F.S.*—Thank you. You will see in our Home Correspondence that your information has been anticipated.

COMMON MELILOT.—*A. B.*—Your specimen is Trefolium melilotus officinalis. It is useful as food for horses, sheep, &c., but is inferior in this respect to another species of the same plant, the Sicilian Melilot, or long-rooted Clover. See Hort. Gram. Woburnensis.

DAIRY VESSELS.—*M. Q.*—We have made inquiries on the subject of your question, and shall soon be able to give you the result.

FAILURE IN CLOVER.—*W. C.*—This may be remedied if the weather and soil be suitable, by sowing Italian Rye-grass over the bare spots immediately after harvest. It would be too late, we think, for Clover.

GRASS.—*Landlord.*—Your specimen is Anthoxanthum odoratum, or sweet scented vernal Grass, of which Mr. Sinclair gives the following character in his Hort. Gram. Woburnensis:—"This Grass constitutes a part of the herbage of pasture on almost every kind of soil, though it only attains to perfection in those that are deep and moist. The chief property that gives merit to this Grass is its early growth. It is a true permanent pasture Grass. It does not appear to be particularly liked by cattle." The latter math is more valuable for grazing than the first crop. It is said to give new-mown hay its odour.

HIGHWAYS—GATES.—*A Constant Reader.*—Such gates as those mentioned by our correspondent are usually tailgates, which are so hung as to shut of themselves; and we think that persons wilfully leaving them open would be answerable for damage thereby occasioned. They appear to be, in fact, the fences of the parties by or for whom they were erected, subject to the easement enjoyed by the public of passing through them and the public must so use the right as not to injure other parties.—*W.*

HOPS.—*A. R. C.*—Sow the seed in March in a south border; keep them for a year in the seed-bed, and then prick them out a foot apart. They require protection for the first winter, as they are tender when young. The seed should be obtained from a female which has been purposely intertwined with a male, so that the flowers may come in contact. We have sent your note to *Ruricola.*

SAWDUST.—*Serra.*—See Mr. Parke's communication on the manufacture of peat charcoal, in a previous Number of this Paper. His suggestions there may be useful to you.

SULPHURIC ACID.—*Carl.*—You will find that the rest of your letter was inserted and answered amongst the Home Correspondence of last week. Use acid diluted with five weights of water; sprinkle it over each layer of manure in the heap, at the rate of 30 lbs. of acid to 5 cwt. of *excrement*, with whatever quantity of litter you may consider that to be mixed in your manure.

VALUE OF ROOTS.—*Querist.*—For the ordinary purposes of feeding sheep and oxen, we consider 20 tons of Swedes, 10 tons of Carrots, and 24 tons of Mangold Wurzel, each at the period when it is best as food, to be equal in value. For particular purposes, however, they differ in value. Thus Mangold Wurzel given to cows does not taint their milk—Swedes do; Carrots, again, are peculiarly valuable as food for horses. Ferns may be destroyed by perseverance in cutting them off as soon as they appear. Their existence in Grass indicates light, sandy, soft land.

***As usual, many communications have been received too late.

Markets.

HOPS, FRIDAY, July 12.

THE accounts from the blighted districts continues to come daily worse, and many Planters say they are past recovery in many places. Midd. Kent continues free from vermin, but mould is on the increase. The market is more active, and speculators buying freely.

FAIRBROTHER & SMITH, Hop-Factors.

HAY.—Per Load of 36 Trusses.

SMITHFIELD, July 12.

Prime Meadow Hay	90s to 95s	Clover	100s to 130s	Straw	28s to 34s
Inferior ,,	80 85				

JOHN COOPER, Salesman.

CUMBERLAND MARKET, July 11.

Superior Old Hay	100s to 105s	Superior Clover	120s to 128s		
Inferior ,,	88 94	Inferior ,,	100 110	Straw	30s to 36s
New Hay ,,	75 80	New Clover ,,	90 100		

JOSHUA BARNS, Hay Salesman.

WHITECHAPEL, July 12.

Old Hay ,,	90s to 96s	Old Clover	110s 130s	Straw	30s to 34s
New Hay ,,	75 80	New Clover	90 100		

Trade very dull at the above prices.

SMITHFIELD, MONDAY, July 8.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 10	to 4s 0	Best Downs & Half-breds	3s 10	to 4s 0
Best Short Horns	3 6	3 8	Best Long-wools	3 6	3 10
Second quality Beasts	3 0	3 4	Ewes and second quality	3 4	3 8
Calves	3 6	4 2	Lambs	4 0	4 8
Pigs	3 4	4 0			

Beasts, 2040; Sheep and Lambs, 21,920; Calves, 796; Pigs, 272.

We have to-day a larger supply of Beasts, but a very great many are of inferior quality; in consequence, the best are readily bought, and do not suffer much abatement in price from last Monday, although the numbers have some effect upon it; some of the most selling Scots, &c., have made 4s 0d, and Short horns 3s 10d, but the greater part of good quality realise very little, if any, over 4s for the former description, and 3s 8d the latter; the middling qualities are a very heavy sale, and several remain unsold. Our numbers of Sheep and Lambs continue large, but we notice good Sheep are not very plentiful; the best qualities are little dearer; there is also rather more demand for the middling qualities since the late rains; 4s 8d for Downs, &c., 4s for Longwools, although realised in some instances, cannot be quoted as general prices. The best Lamb is making a little more money, but a large proportion of the supply of this article is also very inferior, and very difficult to dispose of. Veal-trade is rather brisker. In Pork, no alteration.

FRIDAY, July 12.

The Beast-trade to-day is very dull, at a little less money; the top prices for best Scots, &c., being 4s, and Short-horns, 3s 8d. The Mutton trade is rather heavy, about the same prices as on Monday; Downs, &c. 4s, and Longwools 3s 10d, Ewes, &c. 3s 4d to 3s 8d. There is a slight improvement in the Lamb-trade; some of the most selling qualities have made 4s, but the general price of good Lamb is from 4s 4d to 4s 8d. Veal-trade is a little better, prices running from 3s 8d to 4s 4d. Pork, 3s 4d to 4s. Although there is a shorter market generally, there is fully sufficient to meet the demand.

Beasts, 6,60; Sheep and Lambs, 10,010; Calves, 451; Pigs, 320.

4l, West Smithfield.

WOOL.—BRITISH, FRIDAY, July 12.

Southdown Fleeces	11½	1 1½			

JAMES PEARS, Wool Broker.

COVENT GARDEN, July 13.—The market has been well supplied with Fruit during the week, but Vegetables have been scarce, and generally inferior in quality. Trade remains nearly the same. Pine-apples are equally good and plentiful as they were last week, as are also Peaches and Nectarines, both of which are excellent in quality. Among the former we remarked some particularly fine specimens of Royal George, which are offered at nearly the same prices as last week. Grapes are sufficient for the demand. Some fine Melons are likewise in the market, at about the same prices as last week. Cherries are very abundant, and are a little reduced in price since our last report. Of Strawberries there are plenty, excellent in quality; the chief varieties are Keen's Seedling and Myatt's British Queen. There are also abundance of ripe Gooseberries and Currants, which have not altered in price since our last report. Vegetables are, for the most part, offered at nearly the same prices as last week, except Cauliflowers, which are a little dearer. Cabbages remain about the same, as do likewise Peas, Turnips, Carrots, &c., but French Beans are a little dearer. Potatoes are good and plentiful. Asparagus is nearly over for a season; a few bundles, however, are still in the market. Vegetable Marrow is nearly the same as last week; and no alteration has taken place in the price of Leeks. Lettuces and other salading are plentiful. Cut Flowers chiefly consist of Erica ampullacea, Erythrina crista galli, Ceanothus azureus, Carnations and Picotees, Verbenas, Heliotropes, Pelargoniums, Gardenias, Fuchsias, Lilies, Moss, Provence, and China Roses.

FRUITS.

Pine Apple, per lb., 4s to 8s	Walnuts, pleeling, per bush., 2s 6d to 3s

Horse Radish, per bundle, 2s to 3s	Marjoram, per bunch, 4d to 6d
Savory, per bunch, 2d to 3d	Chervil, per punnet, 2d to 3d
Cucumbers, each, 4d to 1s 6d	

MARK-LANE, MONDAY, July 8.

We had a fair supply of English Wheat at Market this morning, which met a slow sale at a decline of fully 1s. per qr. from this day se'nnight; the transactions in Free Foreign were very limited, and the few retail sales effected brought last week's prices.—The Barley is exceedingly heavy, and must be noted 1s. lower.—Beans and Peas have each declined 1s. per qr.—There is a large show of Oats on the Market, and to effect sales, a reduction of 1s per qr. must be submitted to.

FRIDAY, July 12.

The arrivals of Wheat, both English and Foreign, since Monday, have been moderate, and the trade continues dull at that day's quotations.—There is scarcely any business in Barley, Beans, or Peas, and their value is nominally the same.—Having a large supply of Oats, the Dealers are disposed to refrain from buying for the present, and sales can only be effected to a limited extent, at a further reduction.

Liverpool Corn Trade.

Patronised and sanctioned by HER MAJESTY THE QUEEN, H.R.H. PRINCE ALBERT, the Royal Family, and the several Sovereigns and Courts of Europe.

ROWLAND'S MACASSAR OIL, for the Growth and for Preserving and Beautifying the Human Hair. Price 3s. 6d.; 7s.; Family Bottles (equal to four small), 10s. 6d., and double that size, 21s.

Caution.—The words "Rowland's Macassar Oil" are engraved on the Wrapper of each genuine bottle; and on the back of the Wrapper 1500 times, containing 29,028 letters. Without this "None are genuine."

ROWLAND'S KALYDOR for Improving and Beautifying the Skin and Complexion. Price 4s. 6d. and 8s. 6d. per bottle, duty included.

ROWLAND'S ODONTO, or PEARL DENTIFRICE renders the Teeth beautifully white, and preserves the Gums. Price 2s. 9d. per box, duty included.

Caution.—Spurious imitations are frequently offered for sale as the Real Articles. It is therefore necessary on purchasing to see that the word "ROWLAND'S" is on the Wrapper of each. For the protection of the Public from fraud and imposition, the Honourable Commissioners of Her Majesty's Stamps have authorised the Proprietors' Signature to be engraved on the Government Stamp thus—

A. ROWLAND & SON, 20, HATTON GARDEN; which is affixed on the KALYDOR and ODONTO. Sold by them and by all Chemists and Perfumers.

*** All others are FRAUDULENT COUNTERFEITS!!!

A LUXURY FOR WARM OR WET WEATHER.

BERDOE'S SUPERIOR LIGHT SUMMER FROCKS, WATERPROOF. A variety of the above, in NEW and greatly improved materials (in lieu of the unsightly rubbish made by slopsellers), now ready, guaranteed to exclude any rain whatever; and confidently recommended to those who regard a respectable appearance or wish to avoid disappointment and vexation.

FIRST-RATE CLOTHING of every description, upon the lowest terms possible, consistent with TRUE economy, and ultimate satisfaction.—W. BERDOE, Tailor, Waterproofer, &c., 29, Cornhill. (north side).

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of searching thoroughly into the divisions of the teeth, and cleaning them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose—1s. An improved Clothes Brush, that cleans in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and successful manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the luxury of a genuine Smyrna Sponge. Only at METCALFE'S Sole Establishment, 130B, Oxford-street, one door from Holles-street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

CLEAR WHITE GLASS MILK-PANS.

APSLEY PELLATT, FALCON GLASS WORKS, Holland-street, Blackfriars-road, is still making the Milk-Pans—as described in the *Gardeners' Chronicle*, of clear white flint glass, at 5s. 6d. each, or 3l. per dozen. Early in July A. P. will make the Milk-Pans of green glass of excellent quality, at 42s. per dozen.

PARR'S LIFE PILLS,

THE BEST MEDICINE IN THE WORLD, are now established as the only *certain* cure of disease in the human frame. Sufficient has already been advertised in the public prints to convince any reasonable person that the efficacy of this Medicine is unbounded, and that every disease will soon vanish from the effects of this popular remedy. Already the Proprietors have received and published 26 different sheets of Testimonials; and, besides, have received some thousands of letters confirming all the statements published, and proving the immense benefit derived by all classes by taking PARR'S LIFE PILLS. Testimonials are received daily, and it would be impossible in a newspaper to publish one-half received; and the following are selected as people well known in their respective neighbourhoods, and whose testimony is unquestionable. Further sheets of Testimonials may be had, gratis, of all Agents.

IMPORTANT TESTIMONY of an old man in his 77th year, received by Messrs. MOTTERSHEAD and Co., Manchester, and forwarded to the Proprietors of PARR'S LIFE PILLS.

I, THOMAS BARLOW, gratefully testify to the great benefit I have derived by taking PARR'S LIFE PILLS. I had been out of health for many years; sometimes unable to work, and on the sick club. I had a bad complaint at the stomach, with a violent cough, and at various times was under different medical men, including the noted Dr. Newbold of the Chorlton Dispensary; but my case seemed hopeless, as they none of them could cure, or give me much relief, and I had no hopes left of being better on this side the grave; however, quite unexpected, the deliverer came at last (Old Parr's Recipe). I got a box of his Pills, and found immediate benefit from the first box, and continued them for several months with increased good until this time, and now I feel myself wonderfully well, and am strong in body, have a good appetite, and though in my 77th year, I am able to get my own living, in the employ of Mr. Mee, farmer, Withington (as a farm labourer). I am satisfied that my recovery is to be ascribed entirely to the restorative qualities of PARR'S LIFE PILLS; and as a proof of my great age, subjoined is a copy of my baptismal register.

BAPTISM, 1767.—THOMAS, son of JAMES and MARTHA BARLOW, of Hale, Cheshire, was Baptised the 27th day of November, in the year of our Lord 1767.

From the Parish Register—F. ROWDON.
Signed—JOHN BALDWIN, Vicar.

CAUTION TO THE PUBLIC.

*** Beware of Spurious Imitations of the above Medicine. None are genuine unless the words "PARR'S LIFE PILLS," are in WHITE LETTERS on a RED GROUND, engraved in the Government Stamp, pasted round each box; also the facsimile of the signature of the Proprietors, "T. ROBERTS and Co., Crane Court, Fleet-street, London," on the directions. Sold in boxes, at 1s. 1½d., 2s. 9d., and family packets, 11s. each.

PRINTED FOR

TAYLOR AND WALTON,

BOOKSELLERS AND PUBLISHERS TO UNIVERSITY COLLEGE.

UPPER GOWER-STREET.

DARLEY'S

SCIENTIFIC LIBRARY,

FOR THE USE OF

SCHOOLS, PRIVATE STUDENTS, ARTISTS, AND MECHANICS.

It is the purpose of this Work to furnish a Series of Elementary Treatises on Mathematical Science, addressed to the wants of the public at large. To youth of either sex at public and private schools; to persons whose education has been neglected, or whose attention has not been directed in early life to such studies; and to Artists and Mechanics these little works will be particularly suited. The principles of the various Sciences are rendered as familiar and brought as near to our commonest ideas as possible; the demonstrations of propositions are made plain for the mind and brief for the memory; and the Elements of each Science are reduced not only to their simplest but to their shortest form.

I.

A NEW EDITION (being the fifth) *is now in the Press,*

A SYSTEM

OF

POPULAR GEOMETRY;

Containing in a few Lessons so much of the Elements of Euclid as is necessary and sufficient for a right understanding of every Art and Science in its leading truths and great principles.

BY GEORGE DARLEY, A.B.

Price 4s. 6d., cloth.

II.

NEW EDITION (just published),

COMPANION

TO THE

POPULAR GEOMETRY;

In which the Elements of Abstract Science are familiarised, illustrated, and rendered practically useful to the various purposes of life, with numerous Cuts.

BY GEORGE DARLEY, A.B.

Price 4s. 6d., cloth.

III.

THIRD EDITION,

A SYSTEM

OF

POPULAR ALGEBRA;

WITH

A Section on PROPORTIONS and PROGRESSIONS.

BY GEORGE DARLEY, A.B.

Price 4s. 6d.

"For Students who only seek this limited knowledge of these sciences, there are, perhaps, no treatises which can be read with more advantage than Darley's Popular Geometry and Algebra."—*Library of Useful Knowledge, article "Mechanics."*

IV.

SECOND EDITION,

A SYSTEM

OF

POPULAR TRIGONOMETRY,

Both Plane and Spherical.

With POPULAR TREATISES on LOGARITHMS, and the Application of Algebra to Geometry.

BY GEORGE DARLEY, A.B.

Price 3s. 6d., cloth.

V.

FAMILIAR ASTRONOMY.

BY GEORGE DARLEY, A.B.

WITH ENGRAVINGS.—12mo, 5s., cloth lettered.

"There is a vast deal of astronomical information conveyed in a most winning and unassuming manner in this delightful little volume, which, not less for the novelty of its plan than the extent of its intelligence, reflects infinite credit on the taste and talents of its projector and editor, Mr. Darley."—*Sun.*

*** *Parts I to X each* 1

CHEMICAL ANALYSIS.

One Volume, 8vo, with Numerous Diagrams 10s 6d cloth

ELEMENTS OF CHEMICAL ANALYSIS, INORGANIC and ORGANIC By Edward Andrew Parnell, late Chemical Assistant in University College, London

"As an adjunct to the exertions of the teacher, but by no means superseding the necessity of oral and practical instruction, the work of Mr Parnell appears likely to be in the highest degree useful it will serve to convey to the attentive student a correct notion of the general routine of operations proper to each of the different classes of analytical research, and the principles upon which such modes of proceeding have been devised besides affording him a fund of practical detail, an easy reference to which will certainly lighten his labours and accelerate his progress."—*Chemical Gazette*, Nov 1, 1842

NEW WORK ON ALKALIMETRY, &c.

In One Volume, 12mo, price 4s

NEW METHODS OF ALKALIMETRY, AND OF DETERMINING THE COMMERCIAL VALUE OF ACIDS AND MANGANESE. By Drs Farnell and Will, Chemical Assistants in the University of Giessen Edited by J Lloyd Bullock, late of the Giessen and Paris Laboratories

This little work will prove of the highest importance to Calico Printers, Bleachers, Dyers, Manufacturers of Soda, Paper and Prussiate of Potash, also to Chemists, and to Dealers in Alkalies, Acids, &c.

APPLICATION OF LIEBIC'S PHYSIOLOGY.

In 8vo, 6s

AN APPLICATION OF PROFESSOR LIEBIG'S PHYSIOLOGY TO THE PREVENTION AND CURE OF GRAVEL, CALCULUS, and GOUT By H. Bence Jones, M D, Cantab; Licentiate of the Royal College of Physicians, London; and Fellow of the Chemical Society

LINDLEY'S ELEMENTS OF BOTANY.

8vo, with many hundred figures on wood, 10s 6d.

ELEMENTS OF BOTANY, STRUCTURAL, PHYSIOLOGICAL, SYSTEMATICAL, and MEDICAL; being a Fourth Edition of the Outline of the first principles of Botany. By John Lindley, Ph D, Professor of Botany in University College, London

"This work is indeed what the author intended it to be, 'A Complete Botanical Note Book, wherein all the principal topics which the teachers of Botany introduce into their lectures, are arranged methodically.' The necessity for such works, as pegs for fixing facts in the memory, and giving them their full bearing on their application to reasoning processes, is undeniable; between the skill of the author and that of the engraver, it is scarcely possible to present elementary notices on a simpler and more available plan. One consequence of this is, the impossibility of further analysis. Our readers must therefore rest satisfied with a reference to the work itself."—*Athenæum.*

KNIGHT'S WEEKLY VOLUME.

This day,

ROYAL SURREY ZOOLOGICAL GARDENS.
TUESDAY, JULY 23, 1844.

THE ROYAL SOUTH LONDON FLORICULTURAL SOCIETY will hold their SECOND GRAND MISCELLANEOUS FLOWER SHOW, of Flowers, Fruits, and Vegetables, on which occasion Prizes of Gold and Silver Medals, Vases, &c., will be given for the best Specimens of Picotees, Carnations, Heartsease, Fuchsias, Cut-Flowers, Ericas, Cockscombs, Balsams, Pelargoniums, Carnations, Orchidaceæ, Fruit, Vegetables, and Miscellaneous Plants. And in addition, the beautiful and interesting MODEL OF VENICE. And at Dusk will be exhibited THE GREAT FIRE OF LONDON. Admittance, One Shilling.

THE ANNUAL MEETING of the MIDHURST HORTICULTURAL and FLORICULTURAL SOCIETY, will be held on Tuesday the 17th September, when Prizes will be given for Flowers, Fruits and Vegetables, Particulars of which may be had on or after the 10th August next, on Application being made to Mr. John Thorp, Jun., the Secretary.

YOUELL & CO.'S SPLENDID COLLECTION of FUCHSIAS is now in full bloom, and comprises all the new varieties of the present season. Arboretum gratis.
Great Yarmouth Nursery, July 18, 1844.

ARAUCARIA IMBRICATA.
SPLENDID NEW PINUS.—Fine healthy Plants about 9 inches high, can be had at Hurst and M'Mullen's Seed-shop, No. 6, Leadenhall-street, London, at 5l. per 100.—July 18, 1844.

PRINCESS ALICE MAUDE STRAWBERRY.—This very excellent kind, which has taken first Prizes at most of the Horticultural Shows this season, can be had at Hurst and M'Mullen's Seedshop, No. 6, Leadenhall-street, London, at 25s. per 100. It is the earliest known, and very fine lavoured. Also Myatt's British Queen ditto, at 6s. per 100. July 19th, 1844.

JESSOP'S NURSERY, Cheltenham, Established in 1815, from its extensive connection, offers peculiar advantages to Noblemen and Gentlemen requiring Gardeners, Foresters, or Farm-bailiffs, of established skill and reputation. All communications promptly attended to.

RARE AND BEAUTIFUL COLUMBINE.—The Subscribers beg to intimate that they have saved Seeds of a superb variety of Aquilegia glandulosa. This splendid Columbine is a hardy Perennial, and forms one of the most gay border-plants in cultivation; it grows to the height of from 12 to 18 inches, abounding in two coloured blossoms—blue and white—of the size and shape of the common Passion-flower. Packages of about 150 Seeds are sent free at One Shilling per packet, or for stamps of that value.
John Gregor, and Co., Nurseries, Forres, N.B.

NEW THUNBERGIAS, &c.
JOSEPH FRYER begs respectfully to refer to his Advertisement in last week's *Chronicle*, for particulars of his two very desirable new varieties of Thunbergias—Alata superba, and Aurantiaca superba—which are pronounced by all who have seen them to be superior to anything of the sort ever produced. All orders will be executed in the rotation they are received, as far as the stock will allow.
J. F. likewise begs to offer, as below specified, small plants of which will be sent by post free, or larger carefully packed in hampers.

Fuchsias, all the new varieties sent out this year, each 1s. 6d. to		2 6
" The most esteemed varieties sent out last year (large plants), each		1 0
" A collection of older varieties (large plants) doz.	6	0
Petunias, the finest varieties sent out this year, doz.	10	0
or each	1	0

Seed Warehouse, 86, High-st. (opposite the Town-hall), Boro.

FUCHSIAS.
GEORGE NICHOLS, Gardener, Hunslet Hall, Leeds, begs to offer the following splendid varieties:—

Alice Maud Mary (Bell's)	Princess Royal (Bell's)
Cormackii	Pulcherrima
Prince Albert (Brown's)	Enchantress (Harrison's)
Lowryii	Defiance (Smith's)
Britannia	Majestica (Smith's)
Prince of Wales (Bell's)	Bogfriana
Exoniensis	Gem iveris
Robusta	Eppsii
Fairy Queen (Bell's)	Brockmanni
Iveryana	Transparens
Hero	Magnificent (Bell's)
Lanceli	Magician

Price 12s. per dozen, varieties selected by the purchaser; or 9s. per dozen, selected by G. N.
No charge for hamper. A remittance expected from unknown correspondents.

WOODLANDS NURSERY, Maresfield, near Uckfield, Sussex.
VERBENA HUDSONII.
WM. WOOD AND SON, having purchased the entire stock of the above magnificent VERBENA, beg leave to solicit attention to Dr. Lindley's opinion of it in the *Gardeners' Chronicle*, July 6th, p. 446.
"*W. W.*—Hudsonii is a good variety, bright rosy purple, with a white eye, distinct in colour." To which description W. W. & S. may be allowed to add, that the flowers are large and very showy; it has been seen by several competent judges, who have pronounced it to be a variety of first-rate merit. Plants will be ready for sending out on the 20th August next, packed in tin cases and forwarded post-free, at 3s. 6d. each, with the usual allowance to the Trade when six plants or more are taken at once.
A remittance will be expected from unknown correspondents.

WOODLANDS NURSERY, MARESFIELD, near UCKFIELD SUSSEX.
SUPERB NEW FUCHSIAS, PETUNIAS, VERBENAS, &c.
WILLIAM WOOD AND SON have much pleasure in offering the following selection of the above, in fine condition for autumnal flowering, strong plants of which are now ready for sending out.

FUCHSIAS.

Also the following fine varieties, at 9s. per dozen, the selection being left to the purchaser, or one plant of each for 12s.:—Amethystina, Barnali, Beauty, Bishopii, Boule de feu, Bridesmaid, Burleyana, Fortune-teller, Harlequin, Howardiana, Joan of Arc, Laconii, Minstrel Boy, Renown, Rival King, Speciosa, Tagliani, White Perfection.
W. W. & Son have also on hand an extensive collection of Camellias, Miscellaneous Plants, &c., priced Catalogues of which may be had on application.
. Agents by appointment for the sale of WHITNEY'S TRANSPARENT COMPOSITION, for covering Greenhouses, Frames, &c. Sold in bottles—pints 2s. 6d., quarts, 4s. 6d. each, with printed directions for use.

NEW PANSY-SEED
WILLIAM CLARK, 25, Bishopsgate-street Within, London, is now sending out SEED just gathered, warranted from the best flowers, and can confidently recommend the same, knowing the kinds collected from. In papers of 2s. 6d. and 5s. each. Also J. H. Cox, Esq.'s superb PICOTEE SEED, 5s per paper, may be had, on receipt of a Post-office order.

CLOTH OF GOLD NOISETTE ROSE.
H. CURTIS begs to inform the Nobility and Gentry he has a few Plants remaining of the above highly-desirable double yellow Autumnal Blooming Rose, which would yield several good buds for inserting this summer. Plants, 10s. 6d., package and carriage to London included.—West of England Rose Nursery, Moorend, near Bristol.

SHILLING'S QUEEN CABBAGE.—This month and part of August being the time to sow Cabbage Seed for the Autumn and Spring Planting, J. & S. SHILLING having a little Seed left of the above very superior kind, which they highly recommend to those who have not already tried it—beg to offer it to the Public generally, in half oz. packets, postage free, at 2s. 6d. each, on the receipt of postage stamps or a Post-office order.—Northwarnbro' Nurseries, Odiham, Hants.

BENTALLS' IMPROVED PAPER FOR DRYING PLANTS.
W. AND T. BENTALL, in soliciting the attention of Botanists to the above Paper, beg to submit to their notice the following, as one of the numerous Testimonials with which they have been favoured:—
"Gentlemen,—Though my trial of your new Botanical Paper has been short, I think it may safely be pronounced the best combination of the qualities required in such paper that I have hitherto met with, after trying several kinds, both British made and Foreign.
"It seems probable that your Paper will prove more serviceable to the Botanical traveller than the thick grey Paper often sent with specimens from Germany, and much esteemed by English Botanists; but having the serious defect of extreme liability to tear, which does not appear in your Paper. It certainly ought to supersede the demy Grey recommended in the Instructions issued by the Botanical Society of Edinburgh."—*H. C. Watson, Esq., F.L.S., Vice-President of the Botanical Society of London.*
Professor Lindley, University College, London, & C. C. B. Babington, Esq., F.L.S., St. John's College, Cambridge, have also kindly allowed the use of their names as strongly recommending it.
May be had of the Manufacturers, Halstead, Essex; and of their agents, Mr. E. Newman, 9, Devonshire-street, Bishopsgate-street, London; and Mr. D. S. McIntosh, 12, Catharine-street, Edinburgh.
For Sizes & Prices, see *Gardeners' Chronicle*, June 8th & 15th.

LYNDON'S PATENT SPADE.—Sold by Green and Constable, Ironmongers, 36, King William-st., London-bridge. Horticultural Tool Chests, Bright Ladies' Spades, Mowing Machines, Water Pots, Lord Veseey's Patent Hoes, with a general assortment of Garden Implements.

CURTIS'S BUDDING KNIFE.—"This is the neatest Budding-knife we have seen. The ivory handle is shaped like the blade of a curved penknife, sharp, and turned up at the point, and is evidently extremely well contrived for the purpose it is intended."—Opinion of Professor LINDLEY, in the *Gardeners' Chronicle*, July 20, 1843.

GEORGE PLUM, Surgical Instrument Maker and Cutler, No. 262, Strand, London, and at No. 3, Dolphin street, Bristol, begs to call the attention of the public to the above new and desirable article, manufactured solely by him. Sent free to any part of the kingdom, on receipt of 38 postage stamps, or a post-office order for 3s. 2d.

MAGICAL EFFECT ON FLOWERS.—*Gardeners' Chronicle*, April 27th.—"I cannot speak of POTTER'S LIQUID GUANO in adequate terms of praise. I tried it on Hyacinths, and other Flowers. The effect was magical. My flowers were the finest I ever beheld, and they preserved their beauty nearly double their usual time."—*W. Kidd, Hammersmith.*

"I write to describe the wonderful efficacy of POTTER'S LIQUID GUANO: Peas, Onions, and Asparagus have been singularly improved by it. People came to admire the appearance of the garden."—See *Chronicle*, p. 406.

*** Beware of an ineffectual imitation. See *Chronicle*, p. 406—"Humphreys's Compound."

Sold by most Chemists and Seedsmen.

Factory, 28, Upper Fore-street, Lambeth.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

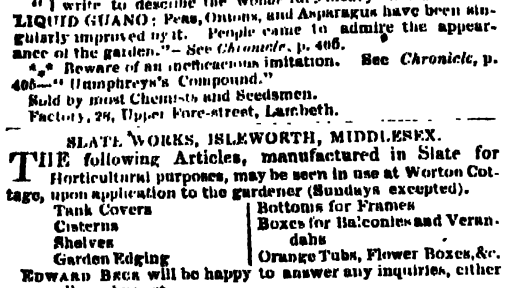
Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	
Garden Edging	Orange Tubs, Flower Boxes, &c.

EDWARD BECK will be happy to answer any inquiries, either personally or by post.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.



D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

KNDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. Mr. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

HORTICULTURAL BUILDING & HEATING by HOT WATER.

J. WEEKS and Co., ARCHITECTS, &c., Gloucester-place, King's-road, Chelsea, Hothouse-Builders, and Hot-water Apparatus Manufacturers, beg leave to inform the Nobility and Gentry, that their business, which has been extensive throughout the country for many years, is entirely confined to the BUILDING OF HORTICULTURAL ERECTIONS of every description, and the HEATING of them by HOT WATER.

CONICAL and other BOILERS of all sizes; their largest consumes but a small quantity of fuel, only requiring attention once in 10 hours, and will heat a range of Forcing-houses 300 feet in length.

Their improved plan of BOTTOM-HEAT FOR PITS, by means of an open trough under the bed, is now being universally adopted.

References may be had, and their works seen at most of the Nobility and Gentlemen's seats in the country, nearly the whole of the London Nurseries, and a great variety of Horticultural Erections and Hot-water Apparatus, Models, Plans, Estimates, &c., at their Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane-square.

TURNIP SEASON.

[illegible] awaits (Foreign and Potter's), RAPE-DUST, [illegible]DUST, CLARKE'S COMPOST, and all other [illegible]r the TURNIP CROP, to be had on the best [illegible] FOTHERGILL, 68, Upper Thames-street.

HORTICULTURAL SOCIETY of LONDON.—EXHIBITION AT THE GARDEN, July 13th, 1844.

INSTRUCTIONS TO THE JUDGES AS TO THEIR CONSIDERATION OF THE NOVELTY OF THE OBJECTS EXHIBITED.

In forming your opinion of the subjects submitted to you for examination, you are requested to take into consideration whether they have been exhibited previously or not. The object of this regulation is to give specimens produced at the Society's Garden Meetings, for the first time, an advantage over others previously exhibited, although of equal merit; and to obstruct the system of exhibiting very fine plants repeatedly, to the disadvantage of others. The EFFECT of this regulation should be,—1. That if two collections should be nearly the same in point of merit otherwise, that in which no previously exhibited specimen shall be found, will be regarded as the better of the two. 2. That in all cases of doubt, the person who had not exhibited previously shall have the benefit of the doubt. 3. That when each of two competitors shall have introduced previously exhibited plants into his collection, that collection which contains the fewest of them shall be deemed the superior if they are otherwise nearly alike. It is not, however, wished that the previous exhibition of plants should depreciate their value so much as to place a superior collection below one very decidedly inferior. The APPLICATION of this regulation is left to your judicious consideration.

AWARD OF THE JUDGES.

LARGE GOLD MEDAL.

1 To Mr. Mylam, Gardener to Sigismund Rucker, Esq., jun., F.H.S., for a collection of Exotic Orchidaceæ

GOLD KNIGHTIAN MEDAL.

1 To Mr. Robertson, Gardener to Mrs. Lawrence, F.H.S., for a collection of 30 Stove and Greenhouse Plants
2 To Messrs. Rollisson, of Tooting, for a collection of Exotic Orchidaceæ
3 To Mr. Don, Gardener to F. G. Cox, Esq., of Stockwell, for six species of Exotic Orchidaceæ
4 To Mr. Spencer, Gardener to the Marquess of Lansdowne, F.H.S., for a miscellaneous collection of Fruit.

GOLD BANKSIAN MEDAL.

1 To Mr. Frazer, of Leyton, Essex, for a collection of 15 Stove and Greenhouse Plants
2 To Mr. Staines, of Middlesex-place, New-road, for 12 varieties of Pelargonium, in pots of 24 to the cast
3 To Mr. Catleugh, of Hans-place, Sloane-street, for the same
4 To Mr. Dobson, Gardener to Mr. Beck, of Isleworth, for 12 varieties of Roses in pots
5 To Messrs. Lane and Son, of Great Berkhampstead, for 25 varieties of Roses in pots
6 To Mr. Robertson, for a collection of Exotic Orchidaceæ
7 To Mr. Redding, Gardener to Mrs. Marryatt, F.H.S., for six species of Exotic Orchidaceæ
8 To Mr. Robertson, for 20 varieties of Cape Heaths
9 To Mr. T. Jackson, F.H.S., for the same
10 To Mr. Henderson, Gardener to Sir George Beaumont, Bart., for a miscellaneous collection of Fruit

SILVER GILT MEDAL.

1 To Mr. W. Cock, F.H.S., of Chiswick, for 12 varieties of Pelargonium, in pots of 24 to the cast
2 To Mr. Gaines, of Battersea, for the same
3 To Mr. Catleugh, for 12 varieties of Pelargonium, in pots of 12 to the cast
4 To Mr. Epps, of Maidstone, for a collection of 15 Stove and Greenhouse Plants
5 To Mr. Bruce, Gardener to Boyd Miller, Esq., for a collection of six Stove and Greenhouse Plants
6 To Mr. Frazer, for a collection of six Stove and Greenhouse Climbers
7 To Mr. Green, Gardener to Sir Edmund Antrobus, Bart., F.H.S., for a collection of 20 varieties of Cape Heaths
8 To Messrs. Fairbairn, of Clapham, for the same
9 To Mr. Bruce, for a collection of six species of Cape Heaths
10 To Mr. J. W. Dawson, of Brixton Hill, for the same
11 To Messrs. Veitch and Son, of Exeter, for Cattleya Loddigesii
12 To Mr. Robertson, for Saurauja spectabilis
13 To Mr. Potts, of Shrewsbury, for Plant-cases on Mr. Ward's plan
14 To Mr. Dytche, Gardener to Sir F. Goodricke, of Studley Castle, Warwick, for Grapes
15 To Mr. Hamp, Gardener to James Thorne, Esq., of Mawbey House, South Lambeth, for the same
16 To Mr. J. Davis, of East Barnet, for the same
17 To Mr. Hamp, for Pine Apples
18 To Mr. M'Ewen, Gardener to Colonel Wyndham, of Petworth, for the same
19 To Mr. Parsons, Gardener to A. George, Esq., of Ponder's End, near Enfield, for the same
20 To Mr. Brewin, Gardener to R Gunter, Esq., F.H.S., for the same

LARGE SILVER MEDAL.

1 To Mr. Green, for a collection of 15 Stove and Greenhouse Plants
2 To Mr. Stowe, Gardener to W. R. Baker, Esq., F.H.S., for a collection of six Stove and Greenhouse Plants
3 To Mr. Gaines, for 12 varieties of Pelargoniums, in pots of 12 to the cast
4 To Alexander Rowland, Esq., F.H.S., for a collection of Roses, in 50 varieties
5 To Messrs. Paul and Son, of Cheshunt, for the same
6 To Mr. Epps, for a collection of 20 species of Cape Heaths
7 To Mr. J. Doran, Gardener to T. Hawes, Esq., F.H.S., for a collection of six species of Cape Heaths
8 To Mr. Frazer, for the same
9 To Mr. C. Embleton, Gardener to Thomas Barnard, Esq., of Park-terrace, North Brixton, for a collection of 24 varieties of Carnations
10 To Messrs. Norman, of Woolwich, for the same
11 To Mr. Embleton, for a collection of 24 varieties of Picotees
12 To Mr. Dickson, of Acre-lane, Brixton, for the same
13 To Mr. Gaines, for a collection of 12 varieties of Fuchsia
14 To Mr. Laing, of Twickenham, for the same
15 To Mr. Dods, Gardener to Sir George Warrender, Bart., F.H.S., for a miscellaneous collection of Fruit
16 To Mr. Robinson, Gardener to A Sinclair, Esq., of Hill-side House, Liverpool, for Grapes
17 To Mr. Ingram, Gardener to Her Majesty, at Windsor, for Royal Albert Grapes
18 To Mr. Wilmot, of Isleworth, F.H.S., for Grapes
19 To Mr. T. Belton, Gardener to Charles Winn, Esq., F.H.S., for Pine Apples
20 To Mr. Wilmot, for the same

SILVER KNIGHTIAN MEDAL.

1 To Mr. George Stanly, Gardener to H. Berens, Esq., F.H.S., for a collection of six Stove and Greenhouse Plants
2 To Messrs. Lane and Son, for a collection of Moss Roses, in 12 varieties
3 To Mr. N. Wilson, Gardener to Earl Howe, F.H.S., for a collection of Roses, in 50 varieties
4 To Messrs Lane and Son, for the same
5 To Mr. Buttery, Gardener to F. R. Symons, Esq., of Norbiton Park, Kingston, for a collection of Roses, in 25 varieties
6 To Mr. E. P. Francis, of Hertford, for the same
7 To Mr. Glendinning, of Turnham Green, F.H.S., for a collection of six species of Cape Heaths
8 To Mr. Willmer, of Sunbury, for a collection of 24 varieties of Carnations
9 To G. Edmonds, Esq., of Wandsworth-road, for a collection of 24 varieties of Picotees
10 To Messrs. Norman, for the same
11 To Messrs. W. P. Ayres, Gardener to J. Cook, Esq., F.H.S., for 12 varieties of Fuchsia
12 To Mr. Kendall, of Stoke Newington, for the same
13 To Mr. Eyles, Gardener to Sir George de Hochepied Larpent, Bart., F.H.S. for Calanthe plantaginea
14 To Messrs. Mountjoy and Son, of Ealing, for a collection of Lilium eximium
15 To the same for a collection of Gloxinias
16 To Mr. Dobson, for a collection of Achimenes
17 To Mr Robertson, for Nepenthes distillatoria
18 To Mr. Fyles, for Chloeneus racemosa
19 To Mr. Robertson, for the best named collection, (*no error in 30 plants, and beautifully written.*)
20 To Mr. Parker, Gardener to J. H. Oughton, Esq., of Roehampton, for a miscellaneous collection of Fruit
21 To Mr. Atlee, Gardener to H. Beaufoy, Esq., of South Lambeth, for Grapes
22 To Mr. Dods, for the same
23 To Mr. Davis, Gardener to Abel Smith, Esq., M.P., F.H.S., for the same
24 To Mr. Smith, Gardener to Sir Gore Ouseley, Bart., F.H.S., for the same
25 To Mr. Mitchell, of Kemp Town, near Brighton, for the same
26 To Mr. Sellers, Gardener to L. V. Watkins, Esq., F.H.S., for Pine Apples
27 To Mr. Davis, of East Barnet, for Nectarines
28 To Mr. Snow, Gardener to the Earl de Grey, F.H.S, for a collection of Peaches and Nectarines
29 To Mr. M'Ewen, for Figs
30 To Mr. Ingram, for Green Gage Plums

SILVER BANKSIAN MEDAL.

1. To Messrs. Cobbett, for a collection of Moss Roses, in 12 varieties
2 To the same, for a collection of Roses, in 50 varieties
3 To Mr. Slowe, for a collection of Roses, in 25 varieties
4 To Mr. Cripps, of Tunbridge Wells, for the same
5 To Mr. Ward, of Woolwich, for a collection of 24 varieties of Carnations
6 To the same, for a collection of 24 varieties of Picotees
7 To Mr. Willmer, for the same
8 To Messrs. Lane and Son, for 12 varieties of Fuchsia
9 To Messrs. Henderson and Co., Pine-apple-place, Edgeware-road, for the same
10 To Mr. Robertson, for Achimenes grandiflora
11 To Mr. Bailey, Gardener to the Lord Archbishop of York, F.H.S., for Crassula grandiflora miniata
12 To the same, for Crassula nitida
13 To Mr. G. Hyde, Gardener to B. Cotten, Esq., of Park House, Wanstead, for Lisianthus Russellianus
14 To Mr. Frazer, for Crowea saligna.
15 To Mr. Robertson, for Medinilla erythrophylla
16 To the same, for Erica radiata
17 To Mr. May, of Woodford, Essex, for Tristania nerifolia
18 To Mr. Bailey, for a miscellaneous collection of Fruit
19 To Mr. Umpleby, Gardener to H. Benyon, Esq., of Roundhay, Leeds, for Grapes
20 To Mr. J. Godfrey, Gardener to the Earl of Limerick, for the same
21 To Mr. Parsons, for the same
22 To Mr. Chapman, for the same
23 To Mr. Henderson, for Pine Apples
24 To Mr. Spencer, for Peaches and Nectarines
25 To Mr. C. Ewing, Gardener to O. F. Meyrick, Esq., F. H. S. for Peaches
26 To Mr. Ferguson, Gardener to his Grace the Duke of Buckingham, for Nectarines
27 To Mr. Fleming, Gardener to His Grace the Duke of Sutherland, F.H.S., for Peaches
28 To Mr. Stanley, for a collection of Madras Citrons
29 To Mr. Pedrick, Gardener to H. Pownall, Esq., for Black Tartarian Cherries
30 To Mr. Redding, for Cherries
31 To Mr D. Caldwell, Gardener to E. Bligh, Esq., for a specimen Orange
32 To Mr. Baxter, Gardener to J. W. Cressey, Esq., of Poplar Cottage, Shepherd's Bush, for Cherries
33 To Mr. Meyers, of Brentford, for the same
34 To Messrs. Rollisson, for the second best-named collection, (*one error in 30 plants.*)

THE CERTIFICATE OF MERIT.

1 To Mr. Catleugh, for a collection of 24 varieties of Carnations
2 To Mr. J. T. Willmer, of the King's-road, Chelsea, for the same
3 To Mr Kendall, of Stoke Newington, for a seedling Fuchsia, (Erecta elegans.)
4 To Mr. Gaines, for a seedling Pelargonium, (Duchess of Lancaster)
5 To Mr. Willmer, of Sunbury, for a seedling Carnation, (Mayo)
6 To Mr. Norman, for a seedling Picotee, (Beauty)
7 To Mr. W. Cock, F.H.S., for a collection of Balsams
8 To Mr. Cuthill, F.H.S., for Lisianthus Russellianus
9 To Mr. Dawson, of Brixton, for Erica ampullacea major
10 To Mr. Hopgood, of Bayswater, for Sollya linearis
11 To Mr. Robertson, for Achimenes longiflora
12 To Messrs. Henderson, for Erica tetragona
13 To Mr. Robertson, for Erica eximia
14 To the same, for Erica tricolor elegans
15 To Mr. Gad, Gardener to T. Lenox, Esq., F.H.S., for Brugmansia floribunda
16 To Mr. T. Jackson, F.H.S., for the third best-named collection, (*one error in 20 plants*)
17 To Messrs. Fairbairn, for the fourth best-named collection, (*one error in 20 plants*)
18 To Mr Mylam, for the fifth best-named collection, (*two errors in 33 plants*)
19 To the Hon and Rev. Robert Wilson, F.H.S., for Raspberries
20 To Messrs. Youell and Co., of Great Yarmouth, for Fastolff Raspberries

*** In consequence of CC. 2, CC. 9, CC. 4, CC. 10, having been exhibited as *new or rare* plants, instead of miscellaneous plants so far as the three first are concerned, and as a single specimen of Orchidaceæ in the case of CC. 10, the Judges have been obliged to pass them by, instead of assigning them the Medals which they would otherwise have received. They must also add that Brugmansia floribunda *scarcely* comes within the meaning of new or rare plants.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL;

And by their Agents, COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.

47, Lime-street, July 20, 1844.

GUANO.—For Sale, in bags of 1 cwt. each; just landed, with a succession of cargoes to arrive.

There being considerable variety in the qualities of Guano imported from different places, and indeed from the same island, each parcel will be chemically analysed with the utmost precision, to show its relative productive power. A copy of such analysis will be given to buyers, and also instructions as to the most approved mode of using the Guano, furnished by the experience of eminent Agriculturists in England and Scotland.

Large parcels will be delivered direct from the Ship, or waterside premises. Smaller quantities may be had at the warehouses, 24 and 25, Billiter-street; or delivered within any reasonable distance, at a trifling additional cost.—Apply to JAMES CLARK, 24, Billiter-street.

THE COUNCIL
OF THE
Horticultural Society of London

Having ascertained that a very large number of the Exhibition Tickets of the present season have not been used, chiefly on account of the unfavourable weather of the 13th—the last day fixed for the Exhibitions; and

HIS GRACE THE DUKE OF DEVONSHIRE,

the President of the Society, having most kindly offered again to throw open the grounds of Chiswick House,

NOTICE IS HEREBY GIVEN,

That there will be on WEDNESDAY, the 31st of July, a MUSICAL PROMENADE in the Society's Garden, at which the unused Tickets of the present season will be received. Other Tickets for the occasion will be issued till the 30th inst. at this Office, price 3*s.* 6*d.* each, or at the Garden on the 31st inst., at 5*s.* each; under the regulations already in force for governing admission to the Exhibitions at the Garden. The usual refreshments will be supplied by Messrs. Gunter.—21, Regent-street.

The Gardeners' Chronicle.

SATURDAY, JULY 20, 1844.

MEETING FOR THE TWO FOLLOWING WEEKS.
TUESDAY, July 23 South London Floricultural . 1 P.M.

At last, after 36 fine or nearly fine days spread over 12 years, the HORTICULTURAL SOCIETY have experienced a wet meeting, which was the more unfortunate, because his Grace the Duke of Devonshire, the noble President of the Society, had opened his beautiful park and gardens to the enjoyment of the visitors, and an unusual abundance of the most accomplished military musicians had been provided, to enliven the scene among the promenaders.* Nevertheless, 4278 persons thronged into the tents and grounds, as regardless of the pitiless rain as they were in May of the bitter wind.

The Exhibition was by far the best we ever saw in the Garden in July, and we incline to think it in some respects the finest of the present season. Of the Orchidaceæ, the single specimens, such excellent tests of cultivation, and, indeed, of the majority of the plants, it is impossible to speak in terms of too much praise. The fruit, however, was the great thing. Conceive 96 Pine apples, 300 or 400 lbs. of Grapes, and endless dishes of all sorts of other kinds, capitally grown, packed in close order upon a very large circular table, tier above tier, and some notion may be formed of this extraordinary spectacle. We find that as many as 44 Medals were distributed among the competitors.

Although it is impossible on occasions of this kind for everybody to win Medals, yet we do think it due to the exhibitors to say, that we remember the time when the worst of those who showed last Saturday would have stood a fair chance for first-class Medals; so much has gardening advanced of late.

The system of offering rewards for correct labelling has of course produced its effect. It has not only caused the plants to be in almost all cases correctly and legibly named—a great convenience to the spectator—but it has turned the attention of the exhibitors to the importance of spelling the names of their plants with exactness In the great collection exhibited last Saturday by Mr. Robertson, gr. to Mrs. Lawrence, there was not a single error which the critic could detect, and the writing of the labels was a beautiful specimen of penmanship Some people may think this a point of no importance, and that it matters not at all whether a man writes and spells well or not, so that he is intelligible. Such persons will also think that it is all the same whether they grow their plants well or ill, so that they do it well enough to keep their places.

It is hopeless to expect that great meetings of this sort should always pass off without errors on the part of the various persons engaged in doing in six hours what ought to consume twenty-four—and in these we include exhibitors, judges, and the officials of the Garden. But if there is one source of error less excusable than another, it is that of mis-entries by the exhibitors. The Society gives the fullest explanation of the classes in which plants are shown; printed papers, explaining in ample detail all that it is necessary to know, are distributed by thousands, to say nothing of advertisements; and yet persons will bring their plants to the Exhibition without having once examined the regulations, and place them in classes to which they in no manner belong; the consequence of which is their being disqualified. It may be said that this signifies to nobody except the exhibitors, who are sufficiently punished for their negligence by the loss of their medals; but we cannot look at the matter exactly in that way. We never see without regret fine specimens, which must have cost the grower much care and solicitude, and which he has perhaps been nursing for weeks, in the laudable hope that they might at last gain for him some honourable distinction, passed by, merely because they are put into wrong classes. It is distressing that the error of a moment should thus nullify the labour of weeks. Yet this constantly occurs, and the Society can neither prevent nor remedy it. For example:—Last Saturday there were the following specimens, all of them well grown, and creditable to anybody, which experienced this disaster. One of the best plants we ever saw of Gloriosa superba, from Mr. Gad, gardener to Thomas Lenox, Esq., a capital Erica tricolor from Messrs. Henderson, Pine Apple Place, and a very nice Statice sinuata, from Mr. Thomas Jackson of Kingston, were all passed over because they were shown, as single specimens of new or very rare ornamental plants, which was absurd. And in like manner, a fine Stanhopea oculata, the original variety, and one of the best, a plant introduced to our gardens above fifteen years ago, was also exhibited as a new plant, although there is a class expressly for single specimens of Orchidaceous plants. We do trust that in another year exhibitors will avoid these most unnecessary mistakes.

Now that the last of these great Horticultural meetings is over, we would beg all those who are interested in the success either of them or of gardening, now, when all the circumstances relating to them are fresh in their memory, to state by letter, addressed *To the Vice-Secretary*, 21, *Regent-street*, whatever they can suggest by way of improving the regulations. We can assure them that the Committee, to whom those letters will be submitted, will give them the fullest attention, and will adopt the recommendations wherever they feel that they would be justified in doing so It is probable that the Committee will meet during this month, in order to settle the arrangements for next year.

We stop the press to announce that the noble PRESIDENT of the HORTICULTURAL SOCIETY has, in the kindest manner, offered again to throw open the grounds of Chiswick House to the visitors to the Garden of the Horticultural Society, and that the Council have therefore just decided upon providing a large attendance of Military Bands at a Musical Promenade in the Garden on the 31st inst., to which all the holders of the unused Exhibition tickets of Saturday last will be admitted. For further information we must refer to the advertisement in another place, and to our columns of Saturday next.

Some weeks since a correspondent from Brixton asserted that the fertilising substance extensively sold in the shops under the name of "HUMPHREYS'S SOLUBLE COMPOUND," and stated to form a *liquid Guano* of superior quality when dissolved in water, was "little else than nitrate of soda and common salt," and that a chemist had been unable to find in it a trace of phosphate of lime (p. 405). The following week Mr. Humphreys replied that his Compound contained neither nitrate of soda nor common salt; and *that the phosphoric acid in his article is introduced under a form of far more general application than phosphate of lime* (p. 430). This seems to have excited the attention of Mr. Potter, who (p. 445) after a chemical examination of the material, pronounced the "Compound" to be utterly devoid of phosphoric acid in any shape.

Here we should have been contented to let the matter rest; for Mr. Potter was not likely to peril his reputation as a chemist by an assertion which could be so easily disproved, if untrue. However, Mr. Humphreys persevered in his original declaration, as will be seen by the following not very courteous letter:

"Lest the public should be misled by the insinuations contained in Mr Potter's Letter of last week, I beg leave to show the simple facts of the case. In my communication at page 430, it was stated that the compound *contains phosphoric acid in a form of* MORE EXTENSIVE USEFULNESS *than that of the phosphate of lime*—and that, as the latter salt is insoluble in water, it was absurd to expect to find it in the Compound." On this Mr. Potter remarks:—"Who ever heard of guano without it?" Now, if Mr. P. will refer to the masterly analysis of guano, by Vellacher, given in the "Pharmaceutical Journal," p. 501, he will find that "guano contains no *soluble* salts of lime;" so that the point is, as it were, twice proved. an actual solution of guano itself does not contain lime! Mr. Potter next relates some inefficient chemical experiments, on which he assumes, notwithstanding my previous contrary assertion, that the Compound is "utterly devoid of phosphoric acid in any shape." I shall not notice the personality which follows, further than to hint to Mr. Potter, that the Compound was not put together with the view that it could be analysed by such chemists as himself, and that *the phosphoric acid is used* UNDER A CHEMICAL ARRANGEMENT, *which renders it insoluble* under the action of the test he names, or even of that very superior one in general use, the nitrate of silver. I am sorry Mr. Potter does not fancy my advertisement, which is evidently distasteful to him, exactly in proportion as it will be useful to the public. But one word more:—Mr. Potter speaks of my public statement, that the Compound contains phosphoric acid, as "an unsubstantiated assertion;" I would, therefore, refer him, or any other person, for a corroboration, to Messrs. Davy Macmurdo, and Co., who have manufactured the preparation of phosphoric acid in question, for the Compound.—J. D. HUMPHREYS."

Here, then, is a violent clash of assertions; and it is impossible for the public, which is much interested in the question, to determine what is the truth. Whether Mr. Humphreys's Compound contains phosphoric acid, according to the assertion of its vendor, or does not, as Mr. Potter has affirmed, is a very material fact for the buyer, and one which, since this Journal has been made the scene of contention, we feel bound to answer. We have therefore caused the "Soluble Compound" to be analysed by one of the most skilful chemists of the present day, and the following is his Report:—

"I have examined two samples of 'Humphreys's Soluble Compound.' I find it to be nitrate of ammonia. It contains rather less than 1 per cent. of other matters; namely, iron, from which it derives its colour, lime, alkaline salts, chlorine, sulphuric acid, and phosphoric acid. The quantity of each of the substances is very minute; I have not estimated it The oxide of iron amounts to 0.32 per cent. *I regard them of no value as part of the manure.*"

We shall make little comment on this fact. Analysis proves that Humphreys's "Soluble Compound" contains so little phosphoric acid that it is doubtful whether it exists in it at all. Of 100 lbs. of the Compound 99 lbs. are nitrate of ammonia, and the remaining pound consists of about five ounces of oxide of iron, and *eleven ounces of lime, alkaline salts, chlorine, and sulphuric and phosphoric acids!* So that what Mr. Humphreys calls "a form of phosphoric acid of far more general application and more extensive usefulness than phosphate of lime," is in fact its almost total absence. By this kind of reasoning its total absence would have made it more useful still. Nobody will now dispute his statement, that it is used under a chemical arrangement which renders it invisible under ordinary tests. Those must be delicate tests which can discover a drop in a hogshead.*

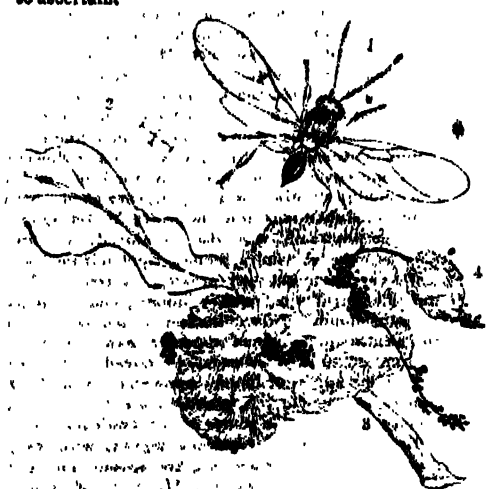
ENTOMOLOGY.

THE WOOLLY OAK-GALL, produced by *Cynips Quercus-ramuli*.—As the galls formed by insects are very remarkable and interesting objects, and the habits of the various species creating them but little known in this country, even by men of science, I shall avail myself of every opportunity to render their histories more familiar to our readers. Having already investigated the economy of several species,† I must refer to my former papers for a general account of the family.

The woolly Oak-galls do not appear to be so common as many other sorts, at least I have never seen them growing; it was, therefore, with much pleasure that I received examples last May, from Mr. Coller, of Normanton Turville; the tree at that period, I learned, was literally covered with these Oak-apples, but none of the common varieties could be found upon it. On opening one of the galls at that time, I found at the base, and amongst the stamina of the male flowers, little brown, woody, oval cells, each containing a minute, white, shining maggot. Towards the end of June I received a fresh supply of these galls; they were not so white as the former, and Mr. Coller informed me that many of them had turned brown and fallen off. In May they looked like balls of white raw cotton, but on closer inspection they exactly resembled short wool, and still more so in June, when they were yellowish, with a pale brownish tinge in parts.

It is certainly wonderful that the puncture of these little flies should produce such a *revolution* in the regular course of nature, as to change flowering buds into large masses of fine threads; and equally marvellous is it, considering the similar conformation of all the Gall-flies that attack the Oak, of which 14 have been described, that the galls of the different species should assume such a variety of appearances; many are round and placed singly, others in groups; some are irregular in outline, spongy, woolly, or mossy; others there are, hard and solid; then, again, the spot selected by each species is unvarying—the upper or under side of the leaves, the footstalks, the catkins, and even the roots, buds, and bark, having each its appropriate Gall-fly.

On examining the woolly galls, I ascertained that they were formed upon the male catkins, which was well ex-



* The following arrangements were ordered to be observed by the military bands on this occasion:—"The bands of the Royal Horse Guards, Coldstreams, Fusiliers, and Royal Artillery, will take their stations in the Society's Garden by one o'clock, and will commence playing as usual. At 25 minutes to 2, P.M; the Coldstreams, the Royal Horse Guards, and the Fusiliers will march to the station of the Royal Artillery, playing the *British Grenadiers' March* in F flat. The four bands will then form themselves into one; and at a quarter to 2 P.M., will play the *Overture to Zampa*, which will be conducted by Mr. Tutton, Bandmaster of the Royal Horse Guards. At the conclusion of this piece, the Fusiliers, Coldstreams, and Royal Horse Guards will resume their stations, and the band of the Royal Artillery will file off in two divisions into the grounds of His Grace the Duke of Devonshire, the whole playing the *British Grenadiers' March* as before. During the afternoon, all the bands will play separately, as usual. At half-past 5 P.M., the band of the Royal Artillery will march back from Chiswick House in two divisions, again playing the *British Grenadiers' March*. One division will be joined on their march by the Blues and Fusiliers, the other division by the Coldstreams, and the whole will resume their first position, again forming themselves into one band. The four bands, thus united, will then play the *March in Oberon* and the *Jubilee Overture*, both of which will be conducted by Mr. Godfrey, Bandmaster of the Coldstreams. At the conclusion of these pieces, the bands will quit the Garden."

[In consequence of the badness of the weather, these arrangements could not be carried into execution. However, at half-past five, the bands collected, and played most admirably the Overture to Zampa, the March in Oberon, and God Save the Queen. The effect thus produced among the trees by wind instruments, played on by 150 of the best performers in Europe, was perfectly enchanting; and we trust the experiment of bringing together large numbers of military instruments will be tried again another year, when we may hope for more favourable weather.]

* Since this was written, we have received a note from Mr. H., in which he states that the phosphate he uses "has its water of crystallisation driven off by heat, so as to reduce it one half in weight; and in this condensed form, 47 grains are added to every pound weight of the Compound." That is to say, he employs 0.67 per cent. of some phosphate, about one-half of which may be regarded as phosphoric acid. We have no doubt of the accuracy of this statement; it agrees very nearly with the analysis above given. But what then? Such homœopathic doses are of no earthly use in gardening; and any mixture containing them may be considered, for practical purposes, to be wholly destitute of phosphoric acid.

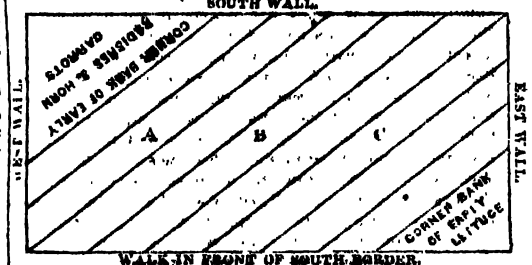
† Vide the *Gard. Chron.*, vol. i., p. 732; vol. ii., p. 852; vol. iii., p. 52; and vol. iv., p. 212.

amplified in the one figured, but they were so closely placed, that as they grew they crowded each other until they appeared like one mass, often as large as the fruit of a Horsechesnut. On the 24th June, and for 10 days or more after, the flies kept hatching in multitudes, and of course, on opening the galls, I found the little pupæ curled up in their cells, where I had detected the larvæ in May. It is an exceedingly curious question, Where do the Gall-flies deposit their eggs at this season? I released at least 500 this morning (28th June) from the box containing the galls, all of which appeared to be males, although some were twice as large as others; on the following day many females hatched, but as there are no catkins upon the Oaks now for them to deposit their eggs in, what can be the nidus selected by the summer brood, which, there is every reason to believe, will die long before winter arrives, for many of the males lived only a few days in the box? It is certainly probable that some of the pupæ may lie dormant in the fallen galls until the ensuing spring, when they may issue forth in due time to puncture the male flower-buds of the Oaks, and thus proceed in their usual course; or it may be that a very few of the females hibernate, for if we reason from analogy, it seems incredible that such immense numbers should be doomed to die without depositing eggs, which are undoubtedly impregnated; yet it is evident if some extensive check were not given to these little animals, no Oak could escape, for they are still hatching in swarms from the few galls I received, and it is very important to observe that up to this time I have not detected a single parasitic fly amongst them; it is true that these may appear at a more convenient season, when the larvæ are in existence, and this I hope to ascertain.

The little fly of the woolly Oak-gall was named by Linnæus Cynips Quercus-ramuli; the *male* (fig. 1, the natural size being shown by the crossed lines, fig. 2), is shining, ochreous or fulvous; the antennæ are long, slender, and 15-jointed, the third joint being the longest; the head is subferruginous, brown at the base, with three large ocelli on the crown; eyes black; thorax with three brown patches before the middle; the scutellum is surrounded with chesnut brown; petiole short; abdomen much smaller than the thorax, intensely black and polished, the apex pointed, with an incurved aculeus capable of elongation; wings pubescent, superior, very long, with a costal cell, a triangular basal one, two submarginal cells, with an imperfect, minute, triangular areolet at their union, from which issues a nervure extending to the posterior margin; the pulvilli and claws are black. The *female* is stouter; the antennæ have only 14 joints; the abdomen is as large as the thorax, ovate-conic, but not acuminated, with an oviduct beneath; it is shining, fulvous, the basal segment only black. Fig. 3 exhibits one of the woolly galls with the anthers of the catkins more or less enveloped, one having a smaller gall produced near the extremity, fig. 4. Curtis's Brit. Ent. may be consulted for the descriptions and dissections of Cynips, pl. and fol. 688; and his Guide Gen., 564, for a list of the species.—*Ruricola.*

FRENCH CULTURE OF THE PELARGONIUM.

(Concluded from page 460.)



Raising from Seed.—The seeds should be sown in the year in which they are matured, or in the spring following. If the seeds have been taken early in July or August, you may sow them immediately; their produce will acquire strength enough to stand the winter, and most of them will bear flowers the following season. The mode of sowing is as follows. Fill pots or boxes within one inch of the top, with good earth well sifted and rather light, smooth it well on the surface, draw lines with your finger, put the seeds into each line, cover them lightly with the same earth, water them, and then place the pots or boxes on the steps in the greenhouse or under a frame. Take care to keep the earth constantly moist, and shade them from too much sun, which would harden the earth, and impede the vegetation. In fifteen or twenty days many of the seeds will be above ground. When the new plants have three or four leaves, put them separately into small pots, keeping as much earth as possible about the roots; water them and put them in a greenhouse or under a frame, shade them from too much sun for a few days, and in less than a week they will have taken root. If you wish to have stronger plants, to flower almost all the spring, put them in an old hot-bed without fresh dung; plant them in such a form that they may be covered with a glass; when they are perfectly rooted remove them sufficiently early to allow them to establish themselves in their new situations before the winter.

Insects hurtful to the Pelargonium.—If the aphis, or green fly, attack the plants in the greenhouse, they are easily destroyed by a strong fumigation of tobacco; this should be done in the morning, when the plants are very dry. In this way plants may be preserved, without fearing that the smoke will injure the plants or flowers. There is another kind of insect which is very destructive to the Pelargonium, produced by a small but tetty, which deposits on the plant its eggs, which the heat of the greenhouse hatches in the autumn and during the winter; these destroyers show themselves by the parenchyma of the leaves being eaten; there is no way of getting rid of them, except by looking for them attentively, and picking them off the plants; and they are very difficult to be seen, because they are usually of the colour of the plant which nourishes them. When the plants begin to show their first flowers, or a short time before, if you think that the fibres spread over the sides of the pot, they must be watered once or twice during the period of flowering, with liquid manure, or water which has percolated through good garden-mould; if the former be used (and it is decidedly preferable), that from the dung of cows is best. This precaution will considerably strengthen the plants during the whole time of their flowering. But such stimulants should not be applied after the buds appear, because they occasion too luxuriant growth of leaves, to the injury of the flowers; experience showing that plants, whose leaves have been too much developed, have fewer flowers, and those of a smaller size, than if the plant was less luxuriant. This observation applies not only to the Pelargonium, but to the Dahlia, and a number of other plants, which run too much to wood, and bear few flowers, when they are planted in a very rich soil. A second flowering of the Pelargonium may be obtained by putting only a part of the collection into the greenhouse; those that are left outside will begin to flower when those that are inside have ceased; these will perhaps be even finer, for it is known that the flowers which bloom in the open air, and under the direct influence of the light, have a more brilliant colour, supposing, of course, that the weather is warm and mild; otherwise, they must be taken in, and put with the rest, because warmth is necessary, in order to obtain large and well-blown flowers. By attention to the foregoing directions, no collection of plants will afford more pleasure than Pelargoniums.

Criterions.—A plant of high merit for propagation should be strong and healthy, not much inclined to run to wood, nor to grow tall; the peduncles slight, but sufficiently firm to support the truss, which ought to consist of from three to five flowers; each flower, clear in colour, should have five petals—two superior, two lateral, and one inferior; or, as it is generally expressed, two superior and three inferior petals. The principal colours are red, orange, rose, and carnation, with their gradations and shades; but lilac is not often admitted. Each of the superior petals must be entirely covered with a large crimson or black spot, well velveted in the centre, surmounted by carmine or lake, more or less deep; but the clearer the spot on the petal, and the more it resembles a fine piece of velvet, the greater its merit. M. Bataille has obtained some varieties in which a spot of the most beautiful velvet entirely covers the upper petals (with the exception of the edge), which spot is embroidered with a white zone that produces the most beautiful contrast. There are some kinds in which the five petals are spotted; it is particularly so in the dark colours, of which there has not yet been found a perfect flower; but as the colour of the lower petals is always lighter than that of the upper ones, so their spots are always less dark. All the petals should be of good substance, very smooth and well united, without any folds or tendency to curl much outwards when the flower is in bloom; and then it should assume as nearly as possible a circular form, which cannot be the case if the petals are narrow and lanceolated, with, of course, a considerable space between them.

Home Correspondence.

Peas.—In these improving times, when every man is expected to render his assistance in giving his mite of information, I beg to state the result of Early Peas as they have proved with me this season, hoping that it may be the means of eliciting from others the result of their experience, so that no one may be tempted in any way to be biassed by what I have myself proved to my satisfaction. Some years ago, but since I have been in practice, it was thought early to have Peas fit for table by George the Third's birthday (the 4th of June); since those days, in different parts of the country, I have gathered Peas from ten to twenty-one days earlier. After a long, dreary winter, every family seems to wish for young Peas as soon as they possibly can get them—no one finds fault on account of their being brought too early to table. In last November, having a south border of late Cauliflowers cleared off, and put into a place of protection for winter purposes, the border was trenched and formed into banks, which were left rough and open to sweeten for Early Peas; having great faith in the Early Warwick Pea for some years, a portion of the banks was sown on the 14th of December; the Peas were above ground on the 28th; in bloom, April 6th; stopped, that is, had their tops pinched off, on the 12th; and were gathered from on May 18th. The height was 4 feet 6 inches, the crop was heavy, and the pods well filled. They were mulched soon after the dry weather set in, which was the means of their continuing to produce good Peas for about thirty days. The banks were 5 feet apart. Cormack's Prince Albert was sown on banks on the same border on the 4th of January, 1844; they were up on the 14th; in bloom on the 1st April; and were gathered entirely on May 14th. I could have gathered a small dish on the 10th of May from them. This is a very prolific and fine-flavoured Pea. On the same day, and on the same border, another portion of the Warwick was sown. These, although having exactly the same treatment as the two above sowings, with regard to banks, hoeing, earthing, sheltering, sticking and watering, stopping or topping, &c., in favour being shown either to one or the other, were in bloom on the 13th of April, and gathered on the 28th of May. Although thus fairly treated, my old favourite Pea was fourteen days behind the Albert. About thirteen years ago I compared the Warwick on a long south border with several others; of these, Early Peas, the Warwick proving itself then superior to the others, retained my favour ever since. Next year, should the Albert prove the same as it has done this year, I can only call the Warwick a Pea for a second crop. Last year I sowed the two above Peas on the same day, under the same preparation and management; the winter, however, was so mild, that they got too "gay," and were very much cut and crippled in the spring, but enough was left to fully prove the superior earliness of the Albert over the Warwick that time. With regard to Shilling's Grotto Pea I have not yet fairly proved its earliness. I sowed it this year to succeed others on an open quarter on the 4th of March. It was above ground on the 12th; in bloom on the 4th of May; and gathered on the 12th of June. Its height was 5 feet. It was not so prolific as the two above Peas. The pods with me were wide and rather short; but it is a fine-flavoured Pea, and of a beautiful colour when cooked.

I find great advantage by sowing Early Peas in the above method; first, they enjoy a greater portion of sun during the short days of winter and in spring; second, the earth lies dry, sweet, and wholesome; third, the banks break the wind from each other, so that the Peas lie well sheltered, although the banks are so sloped that the rows of Peas have the full enjoyment of all the sun; the banks are 5 feet apart, A, B, and C representing them; height of back sloped, 2 feet; sloping to the front, about 3 feet 6 inches; and the Peas are sown or transplanted 1 foot from the bottom. The above method is not only good for the Peas, but the border is so sweetened and pulverised by its being continually hoed, that the crop is sure to do well that succeeds the Peas.—*James Barnes, Bicton.*

Peach-trees.—With regard to "Omikron's" Peach-trees, Mr. Roberts (p. 389) imagines that I lay too much stress on the attacks of insects, and deep and stagnant borders; and he supposes that the cause of disease proceeds rather from ill-ripened wood. Now, this I never doubted: nearly all the evils to which the Peach is liable are traceable to this alone, and for this very reason I both practise and recommend the use of shallow borders, which I consider the very basis of all acclimatising; and this, with the chopped turf, is all that can be desired in that respect; with the latter there is a much greater freedom of root, and earlier action through the months of April and May, at the time I conceive it is much needed; for who would expect good fruit and healthy young wood from torpid roots, imbedded from one foot to three in putrid and stagnant soil? I therefore trust that I shall not be farther misunderstood, for let it be remembered that of the ten fundamental points, which I assumed in my answer to "Omikron" as sound maxims in the cultivation of the Peach, eight at least have a direct reference to the ripening of the wood. Indeed I may say that with me this is everything, and on this alone I rely. Mr. Roberts need be under no alarm about Peach-trees becoming too luxuriant in chopped turf,—such is assuredly not the case, as my trees abundantly prove; they are an exact medium as to strength, and gum is unknown to them; therefore there can be no harm in chopped turf. Perhaps I ought, however, to have written more guardedly. If turf was cut as thin as for turfing lawns, for this purpose, I should not be surprised to find the trees in a showery season too luxuriant; but the turf I use is, perhaps, from 4 to 6 inches thick, and being put in the hole in rough lumps, the water readily escapes. Turf used in this way retains its mechanical properties for many years, and if dug up at the end of ten or fifteen years, will be found of a much more mellow character than what is termed compost; which signifies good soils mischievously handled. I beg to assure Mr. Roberts, that the summer stopping, on which I presume the equalisation of the sap depends, is by no means productive of the evil consequences that he apprehends. When a shoot bursts into laterals, who can expect healthy blossom-buds above that point? It is tolerably evident, then, that this superabundant grossness is maintained at the expense of the lower portions of the

trees. As to flued walls, I admit their utility; but if we Northmen can produce fruit and trees equal to the genial climate of the Southern parts of the island, without the aid of flues, it at least argues in favour of the principles we adopt. I am sorry to see, at p. 389, the propriety of chopped turf disputed by Mr. Lawrence. He appeals to facts—so do I. However, I should expect just such results as actually took place, the border being three feet deep. It is, however, wrong to assume that because three feet of turf is too much, one foot must be the same. I beg to repeat that I plant on the mounds of brick or stone, and consequently have not above ten inches of soil in that part, increasing slightly in depth outwards, and that no trees can look better or have a finer crop of fruit? they have endured all the hot and dry weather without a single drop of water, and the walk over their roots is as hard as a turnpike road. This has taught me a lesson as to the habits of the Peach that I shall not easily forget. Ten assurance years ago, that what is called disease in the Peach is neither more nor less than ill-ripened wood, in the great majority of cases, led me to conclude that any soil which would insure an early action of root, combined with an early check or timely cessation of growth, would be most conducive to this end, and this I find most perfectly accomplished by my present plans. Trees situated as mine are, can never be glutted with moisture; they possess a steady and uniform existence, through the slowly progressive decay of the lumps of turf; manure being unknown, except as top-dressing in cases of exhaustion.—*Robert Errington.*

Vines.—Last season I renewed the Vines in one of my vineries, and in doing this I adopted a plan which I have not seen practised elsewhere. A hole was made in the parapet-wall under each sash, and a rod of the previous season's growth was passed out at one hole and in at another. The border was prepared as follows:—About a foot of the surface of the old border was removed, a small quantity of ashes was thrown in for drainage, and the bottom was then flagged with stones to the width of 2 feet from the wall; at the outside of this a barrier of flags was put up, and the space between this and the wall was divided into as many compartments as there were plants (or layers) in the house; these compartments were then filled in to the depth of 18 inches with prepared soil, the layers being covered about 8 inches; the border was then mulched over, and this finished the operation for the first two years. The 2 feet of soil I consider sufficient for the first two years; on the third, (*i. e.*, next season,) I shall remove the barrier, and with a fork take off part of the soil, to enable me to prune, examine, and arrange the roots, as may appear necessary; having done this, I shall place the barrier about a foot and a half further out, and fill the space up with fresh soil, in the same way as at first; this operation I intend to repeat annually. The advantages are—1st. I will not lose the use of the old Vines until the young ones are quite ready to take their place; 2d. I divide the labour of making the border, which is usually done in one year, over a number of years; 3d. I have a perfect command of the roots of my Vines, and can manage them with as much regularity as I can do the branches; 4th. Should it become necessary from any cause to remove an old Vine, or introduce a new one, it can be done without in the slightest degree interfering with its neighbour; and 5th. They have a fresh supply of soil to produce every crop, and should I wish to feed with liquid manure, I know exactly where to apply it effectually. This system might also be applied with advantage to wall-trees. It might be improved upon, in the case of forming a new house for early forcing, by leaving the compartments larger, and making a trench for fermenting materials, with pigeon-holed brick-work between the compartments, which would enable a temperature to be kept at the roots in some degree corresponding to that in the inside of the house. The connection between the layers and the old Vines was cut off a considerable time before the growing season was over, and the former were so well rooted that they never hung a leaf. They are now growing beautifully, and making as good wood as I could wish.—*W. W.*

Pine-apples.—For the information of "A. B. C." (p. 445), whose Pines have not fruited, I would suggest that if he was to turn his strongest plants in pots out into new tan, it would possibly start them into fruit, and also, in all probability, increase their size. The complaint about Pines not fruiting at the usual season is not new; but a complete remedy for this is at hand, not, however, in the unnatural practice of hungering the plants, neither is it in that of starving or disrooting them, but in encouraging rapid growth, thereby promoting complete development of the plant, and maturation of the fruit. At p. 53 of my "Treatise on the Pine-apple," is stated the result of my own practice. It consists in keeping the plant growing rapidly until the fruit is ripened off, which is usually in about eight or ten months after the Pines are planted out. I would also inform "A. B. C." that, if his plants should fruit this autumn, he may again fruit them in the following autumn. These facts I have a second time this season fully tested, at Thornfield—namely, that the Pine is capable of producing one fruit annually for any length of time. I shall soon be able to ascertain the result of an experiment made with two New Providence Pines—one I turned out into good compost, and the other I planted in the tan; the fruit of the latter is evidently swelling better, according to the size of the plant, than that of the former; and it has not half the size of crown.—*Joseph Hamilton, Thornfield.*

Tall Orchis.—An Orchis maculata measured 7¾ inches long in the flower-spike, with the four topmost buds yet unexpanded; and 2 feet 8½ inches high from the ground. Is not that an unusual size?—*A. H.* [Very.]

Bees.—I would suggest to the "Cottager," of West Dean, Sussex, that in future, when he has occasion to double his stock hives, he should place the empty hive over the other, instead of beneath it. Bees have a disposition to carry their stores upward, and if the "Cottager" had supered his stock, he would probably have found, when he harvested his honey, that the hive would have contained no brood. Under similar circumstances I had three supers last year, which, one with another, contained nearly 12lb. lbs. of honey-comb, uncontaminated by a single brood cell. If the "Cottager" decides upon removing his other super, as the family is populous, I recommend him to replace it by an empty hive, as swarming at this season should be discouraged. In answer to the question, Whether the bees will collect sufficient food for their winter sustenance in case of a protracted removal? I would observe that, if they have not already stored enough, or nearly so, in the nadir hive, which may be ascertained by weighing it, the probability is that the winter's supply of the bees will be deficient, and that they will require feeding. The inquiry, Whether an old stock will not work up as well as down? I have virtually answered already. The bees will work better up than down. I do not know what sized hives the pasturage of West Dean may require, but those described by the "Cottager" are very much too large for any district that ever came under my cognizance.—*Edward Bevan, Egair Evan, Newtown, Montgomeryshire.*

Bees.—In answer to "A Cottager," I have to say that if the bees have destroyed the drones,* he will not have any swarm, although the space is decreased. If the bees are deprived of part of their honey by the removal of a hive in connexion with the main stock, room ought at the same time to be given in some other place, if it is thought desirable to prevent swarming. The best way of managing bees is to have side hives, and when one side hive is taken, to place an empty hive on the other side. The side hives being only wanted for summer, may be made of old packing cases; the smaller they are the sooner they are filled. There should be a window with a shutter in the side hives, to know when they are fit to be taken. I have not had a single swarm since I have understood the conservative plan.—*C. A. A. Lloyd.*

Ants.—Who says there is no effectual remedy for these troublesome little pests? Arsenic and sugar!—Why, they delight in it. Take a saucer, smear the inside slightly with honey, place it inverted near their haunts; in an hour examine the saucer, and see if the honey be all gone; if not, let the saucer remain until it is. When it is all gone repeat it, and let them eat it off. Do this a third time; but now, when many are under the saucer feeding (and I have found hundreds), having with you a basin of boiling water, gently raise the saucer without turning it up, and hold it within an inch or two of the hot water; the Ants feeling the steam will drop, and of course die. Put the saucer, renewing the honey, in the same place, and in a quarter of an hour steam again, and so on, until you destroy all, which will be done in a very short time. According to the numbers two or three saucers may be used if wished; but I have found one always sufficient. By this means you kill all the workers, and by killing them, I need not say you destroy the colony.—*W. H. G.*

* This is usually done in July.

Societies.

HORTICULTURAL SOCIETY.

The last Exhibition of the season in the gardens at Chiswick took place on Saturday last. The day was very inauspicious, the rain beginning to fall just as the company began to enter the garden, and the "pitiless pelting of the storm" continuing with little intermission for hours after the company had left the grounds. This was very unfortunate, as the Exhibition was one of the very best we ever witnessed in July; and in addition to the usual attractions, the beautiful grounds of the noble President of the Society, His Grace the Duke of Devonshire, were thrown open to the public, though but few had courage to avail themselves of the privilege. The leading features of the Exhibition were the noble collections of Orchidaceæ from the gardens of S. Rucker, Esq., Messrs. Rollisson of Tooting, Mrs. Lawrence, Mrs. Marryat, and Mr. Cox of Stockwell; the Roses in Pots, from Mr. Beck and Messrs. Lane; the fine Collections of Plants, from Mrs. Lawrence, Mr. Frazer, Mr. Epps of Maidstone, and others; and the magnificent Collection of Fruit from all parts of the country. The Heaths, Pelargoniums, and Fuchsias, contributed much to enliven the scene, and the Florists' Flowers were not destitute of admirers.

The large Collection of Orchidaceous Plants sent by Mr. Mylam, gr. to S. Rucker, Esq., was very rich, both in novelty and beauty, and contained many noble specimens, evincing the very best management, and in the highest health. Among them were fine plants in perfect bloom of Stanhopea tigrina and cinnamomea, producing their singular flowers beneath the bottom of a wire-basket; the curious plant producing a yellow Maxillaria-like flower spotted with brown, called Scuticaria Steelii; the rare Angulos Clowesii, producing a pale-yellow, or rather lemon-coloured flower; and a noble plant of Miltonia spectabilis, with 15 of its lovely blooms. He had, moreover, a very fine plant of Oncidium Lanceanum in beautiful bloom, with O. luridum guttatum, leucochilum, and pictum. Another very pretty plant was Zygopetalum crinitum cœruleum, which contained more blue in the flowers than is usual in this class of flowers; a curious plant, not quite in bloom, of Sarcanthus rostratus; and very pretty specimens of Cycnoches maculatum, Brassia Lawrenceana, and Lanceana very fine, with Angræcum bilobum, Cycnoches ventricosum, Lycaste Skinneri and macrophylla, Cycnoches chlorochilon, with pale-green flowers; Odontoglossum pulchellum very pretty, the curious Catasetum citrinum and luridum, Huntleya violacea, Maxillaria Warreana and vitellina, Epidendrum fragrans, Galeandra Bauerii, the singular Maxillaria stapelioides, and a species with very pink flowers, called M. tetragona.—Of the curious genus Cirrhæa, there were three species, called picta, lutea, and Warreana, with very curious flowers hanging over the side of the pots, and which would have been better shown had they had a sheet of white paper placed beneath them; and, finally, there was a pretty specimen of the beautiful Stanhopea saccata.—The Collection from the nursery of Messrs. Rollisson, of Tooting, was scarcely less interesting than the preceding, and taken as a whole was very superior to the one produced by the same growers in June. Among them we noticed a fine variety of Calanthe, with rich violet flowers, called C. masuca; a new species or rather variety of Cymbidium, with large dark-brown flowers resembling C. aloifolium; Catasetum deltoideum, with very pretty dark-brown flowers; Stanhopea tigrina, and Wardii very fine; and a plant of Oncidium Lanceanum in fine bloom. Another very beautiful plant was Aerides quinquevulnerum, and there were also neat plants of Miltonia spectabilis, and the lovely Cattleya crispa. The same gentlemen also communicated Acropera Loddigesii, the singular Cycnoches Loddigesii, Epidendrum alatum, Lycaste tetragona, very curious; Isochilus linearis, Aspasia lunata, Rodriguezia recurva, Brassia Lanceana, and Oncidium luridum, all in fine health and bloom.—From the garden of Mrs. Lawrence, Mr. Robertson produced a magnificent plant, not quite sufficiently in bloom, of Peristeria alata, the Panama Dove plant; fine plants of Stanhopea eburnea, oculata, quadricornis; with Xylobium squalens, very curious; and a fine plant of the singular Mormodes citrinum, with yellow flowers. There was, moreover, a fine plant, in good bloom, of Acropera Loddigesii, Maxillaria Deppii, very good; with the curious M. stapelioides, and the pretty M. tetragona. Mormodes aromaticum was also produced, in fine condition; as were Galeandra Baueri, Epidendrum vitellinum, Brassia bracteata, very pretty; Catasetum Russellianum, Phajus albidus, in fine bloom; and Epidendrum odoratissimum. This collection of plants was in excellent health, and showed superior management.—Mr. Redding, gr. to Mrs. Marryat, produced Stanhopea oculata, with six spikes of bloom, somewhat injured by the coldness of the day; S. grandiflora and tigrina, in good bloom; and tolerable plants of Epidendrum variegatum, Brassia Lanceana, Gongora nigrita, with very dark flowers; with Oncidium papilio, altissimum, and pulvinatum.—From the garden of Mr. Cox, of Stockwell, Mr. Don produced Rodriguezia secunda and recurva, Catasetum Russellianum, Calanthe masuca, Cattleya Harrisonii, in fine bloom; the lovely Stanhopea venusta, with Cycnoches chlorochilon, Phajus albus, Miltonia spectabilis, Oncidium flexuosum, and Cymbidium lancifolium.

Of single specimens of Orchidaceæ there was a splendid plant of Cattleya Loddigesii, with nine spikes of bloom, from Messrs. Veitch and Sons, of Exeter; a Stanhopea oculata variety, with twenty flowers, from Messrs. Henderson, of Pine-apple Place; Vanda Roxburghi, a small plant, from Mr. Plant, gr. to H. Schroder, Esq., of Brixton; and a new species of Calanthe, with pale-violet flowers, called C. plantaginea, from Mr. Eyles, gr. to Sir George Larpent, at Putney Heath.

Only one large collection of Stove and Greenhouse Plants was produced, and that came from the garden of Mrs. Lawrence, at Ealing Park. It contained some beautiful plants, which were the more to be admired because they were full-formed specimens, plants that were fit to be seen on all sides, and had not been trained on the now too fashionable method of making one-sided plants, by training the branches to one side only, and leaving the back naked and ugly. Now, however much necessity there was for this method of training in years gone by, when plant cultivation was not quite so well understood as it is at the present time, it is quite certain there is no necessity for such deformity now, and we therefore hope another year to see such plants excluded from competition. The perfection of cultivation is to produce plants perfect on all sides; and although such plants may require more room and more care for their proper management, we think it cannot be denied that they would be very preferable to one-sided plants. While, however, we would insist upon plants being grown into perfect specimens, we must enter our protest against their being brought into proper form by the use of a forest of sticks. All plants ought to be grown so as to require, or at any rate exhibit, as few sticks for their support as possible. Pelargoniums may be grown without sticks, so may Heaths and most other hard-wooded plants. Fuchsias do not require them, and the more they are used the more is the elegant drooping habit of that beautiful flower destroyed. We mention these things here, because many otherwise handsome plants were completely spoiled by an unnecessary and unsightly use of sticks; and this was not confined to Fuchsias only, but to many of the stove and greenhouse plants, and even to some of the Heaths. To proceed with the collections, Mrs. Lawrence's contained a fine specimen of Æschynanthus maculatus, upwards of two feet in diameter, trained hemispherically, and liberally

covered with bloom; Bæleria pulchella, a very pretty plant; Lasiandra petiolata, a plant three feet in diameter, and producing very pretty blue flowers; Phænocoma prolifera, a very fine specimen; Cuphea Melvillai, two large plants producing large scarlet flowers tipped with green; Pentas carnea, a dwarf and well-bloomed plant; Manettia cordifolia, very fine specimens described in our last report, but rather past their best; Statice macrophylla, with a fine spike of bloom; S. sinuata, a neat plant; and a very pretty specimen of Mirbelia floribunda.

In addition to the above, Mr. Robertson produced a remarkably fine plant of Vinca rosea ocellata in perfect bloom; Siphocampylus betulifolius, a good specimen; Achimenes grandiflora, a well-grown and noble specimen in most profuse bloom; two plants of Angelonia Gardneriana, producing prettily-spotted purple flowers, in long spikes, and a great abundance of them; a remarkably fine specimen, before noticed, of Leschenaultia formosa; Asclepias curassavica, a good specimen; a nice plant of Osbeckia chinensis, with rose-coloured flowers; Clerodendrum calamitosum, a pretty specimen; with a beautiful plant of Cassia corymbosa, and a number of other good plants. All that this collection required to render it perfect, especially on a dull day, was a greater number of various coloured flowers, as scarlet, orange, and yellow; but under the present regulations, it is almost impossible to introduce them.—The collection of plants from Mr. Frazer, of the Lea-bridge-road, was particularly remarkable for fine cultivation, and clean and excellent growth Better taste had also been displayed in the selection of the colours, and also in their arrangement on the stage. The most remarkable plant was a very fine specimen of Kalosanthes coccinea, loaded with its bright-scarlet flowers; a very large and admirably-managed plant of Vinca rosea alba, in excellent bloom; Roella ciliata, an admirable plant, 18ins. in diameter, and nearly the same in height, and covered with its beautiful pale blueish-purple flowers; Euthales macrophylla, a lovely plant, four feet high, and the same in diameter, densely covered with beautiful yellow flowers; Angelonia Gardneriana, a very handsome plant; with Crowea saligna, in fine bloom, and good plants of Vinca rosea, and Gardoquia Hookeri, a plant which, generally, is not blooming in good condition this season. Mr. Fraser had also plants in excellent condition of Boronia viminea and Leschenaultia formosa.—Mr. Epps, of the Bower Nursery, Maidstone, contributed a group of 15 plants, among which were some new things, and well-grown specimens of Coleonema rubrum; a fine plant, well bloomed, of Sollya heterophylla; Clerodendrum squamatum, a very dwarf plant, with two spikes of bloom; an admirably-bloomed specimen of Achimenes multiflora; and a tolerable plant of Achimenes grandiflora, apparently from a single crown this season.—Mr. Epps sent a very pretty specimen of Brugmansia floribunda, with orange flowers: a neat plant of Gloxinia Cattoni; and good plants in profuse bloom of Begonia parviflora, Torenia scabra, and Vinca rosea and rosea alba. For a new beginner, this collection was very creditable, especially considering it had been conveyed upwards of 40 miles to the place of exhibition.—Mr. Green, gr. to Sir E. Antrobus, Bart., and Mr. Redding, gr. to Mrs. Marryat, produced collections in the 15th Class, but neither were particularly remarkable. Mr. Green's contained two handsome plants, and these were Coleonema rubrum and Stephanotis floribundus.—Groups of six plants were shown by Mr. Bruce, gr. to Boyd Miller, Esq., of Mitcham, Mr. Stowe, gr. to W. R. Baker, Esq., Bayfordbury Park, Herts, Mr. Stanley, gr. to H. Berens, Esq., Sidcup, Kent, and Mr. Cox of Stockwell. Mr. Bruce's plants were, a very admirable specimen of Pentas carnea, said to have been grown in the open air; Achimenes longiflora, the flowers most beautifully coloured; Aphelexis humilis, a lovely plant; Clerodendrum squamatum, well-grown; and good plants of the old Phymatanthus or Pelargonium tricolor, and Pimelea decussata. The best plants in Mr. Stowe's collection were Bossiæa linophylla, not quite sufficiently in bloom; Crowea saligna, a promising plant; Swainsona galegifolia; Vinca alba; and Campanula Barrelieri.—Mr. Stanley had fine plants of Leschenaultia formosa, Gloxinia Menziesii, and Nuphæa oblonga; but Begonia parviflora, Achimenes rosea, and Vinca ocellata, in the same collection, were spoilt by the injudicious use of sticks.—Mr. Cox's collection was not remarkable.

Of CLIMBING PLANTS, only one collection was produced, and that came from Mr. Frazer. It contained a very handsome specimen of Allamanda cathartica; excellent plants, Sollya angustifolia and linearis, with Manettia cordifolia, Hoya carnosa, and Stephanotus floribundus.

From the Nursery of Mr. Jackson, of Kingston, were a collection of Statices, consisting of S. sinuata, a very pretty species; Pseudo-armeria, a variety with pink flowers, said to be hardy; with S. Gmelini undulata, Dendroni, arborea and incana.—Messrs. [illegible], of Ealing, sent 12 very fine plants of Lilium [illegible], in beautiful bloom, and 6 remarkable well-[illegible] specimens of Gloxinia rubra and maxima alba, [illegible] profusely covered with bloom.—Mr. Dobson, gr. to [illegible] Beck, of Isleworth sent 7 very fine plants of [illegible], but with rather pale flowers; and Mr. Cut[illegible]an, of Camberwell, 10 beautifully grown [illegible] Lanthus Russellianus, a plant for the success [illegible] of which he has been so long celebrated. [illegible] almost all the PLANTS the most remarkable was a [illegible] open air; plant the [illegible]son, called Saurauja spectabilis. [illegible]oking leaves, and flowers in large bunches resembling Spiræa aruncifolia, but shorter in the bunch, and deliciously sweet-scented. Another curious new plant Chiococca racemosa, was produced by Mr. Eyles, gr. to Sir George Larpent. It had small yellow flowers, which were abundantly produced.—Mr. Gad, gr. to Thomas Lenox, Esq., of Plaistow, Essex, communicated a plant of Brugmansia floribunda, in good bloom; Messrs. Mountjoy, a plant of Gloxinia cerina, with pale pink flowers, and said to be a half-bred Sinningia; Mr. Stanley, a species of Thysanotus, the flowers of which open early in the day, but close towards noon; and Mr. Jackson, a plant of Gesneria, with particularly bright scarlet flowers, which were profusely produced.—From the Nursery of Mr. Frazer was a plant of Gompholobium splendens, with yellow flowers; and Mr. Ayres, gr. to James Cook, Esq., sent a plant of a hybrid Achimenes, said to have been raised between A. rosea and coccinea, and called A. Beatoni. It was too near A. coccinea.—Mr. Miller, of the Providence Nursery, Ramsgate, sent a large plant of Petunia punctata, which fully realised all that has been said of it. The flowers open of a bluish purple colour, but as they advance in age becomes marked or blotched with white, and this change continues until the flowers at last are almost wholly white. The plants, however, which we have seen in the open borders, do not at present show any of the spotted character, but continue a dirty purple until they decay; so that, though the plant may do as a curiosity for pot culture, it will never be of any use for bedding out; indeed, to make the most of it, the spotted ones are but faded flowers. A number of other plants were shown in this class, but, unfortunately for the exhibitors, they were entered wrong, and consequently no award of prizes was made to them.

Of SINGLE SPECIMENS, some remarkable plants were exhibited, especially a large specimen of Gloriosa superba, upwards of six feet high, and in splendid bloom. This was by far the best pot specimen of this plant we ever saw, but through a mis-entry no prize was awarded to it.—A very curious plant with pink flowers protruding from all parts of the old wood of the plant, even from the surface of the pot to the extreme point, was sent by Mr. Robertson, and called Medinilla erythrophylla; he had another beautiful and singular plant, called Lemonia spectabilis.—From the Nursery of Mr. Frazer was a magnificent specimen of Crowea saligna, in excellent health; and Mr. Hyde, gr. to B. Cotton, Esq., sent a noble specimen of Lasianthus Russellianus, covered with upwards of three hundred flower-buds.—Mr. Bailey, gr. to His Grace the Archbishop of York, sent two exceedingly well-grown plants of Kalosanthes nitida, and grandiflora minuta; they were three feet high and three feet in diameter, but the bloom was not in proportion to the size of the plants. They were, however, admirable specimens of cultivation, and deserving of all praise.—Statice sinuata, a lovely specimen, was communicated by Mr. Jackson; Achimenes longiflora, remarkably good, by Mr. Bruce; and A. longiflora and grandiflora, superlatively excellent, by Mr. Robertson.—Sedum tortuosum came from Mr. Doran, gr. to Thos. Hawes, Esq.; and Leschenaultia formosa, from Mr. Poole, of Leyton, Essex.—A fine plant of Sollya linearis, was sent by Mr. Hopgood, of Bayswater; Tristania neriifolia, with yellow flowers, by Mr. May, of Woodford; Erica ampullacea, a splendid plant, by Mr. Dawson, of Brixton Hill; E. tricolor superba, by Messrs. Henderson; and E. tricolor elegans radiata, an excellent plant, and eximia, a fine specimen, by Mr. Robertson, who also sent a grand plant, 10 feet high, of Nepenthes distillatoria, the singular Pitcher plant, which was covered with pitchers, and was very much admired. The curious Erica tetragona, and a tolerable plant of E. eximia, were sent by Mr. Hudson.

A number of Collections of HEATHS were shown by various persons, and among them were some admirable specimens.—Mr. Robertson produced fine plants of Parmenteriana rosea; gemmifera, in fine bloom; depressa, an excellent specimen, in perfect health and bloom; viridiflora, with green flowers, a good plant; cerinthoides major, an excellent plant; jasminiflora alba, a good plant, in perfect bloom; Cavendishii and ampullacea, both good; a nice plant of obbata, and another of ampullacea vittata. Mr. Robertson had, moreover, good plants of a variety called Lannonii, with ventricosa rosea, globosa, and superba; and also eximia radiata, tricolor elegans, and inflata alba.—Mr. Jackson's collection consisted of E. ampullacea and a. rubra; cerinthoides, a fine plant; Westphalingia, in fine health and bloom; jasminiflora alba, Jacksoni, a fine plant; Massoni, in good bloom; tricolor superba, fine; and a seedling variety, equally good; ventricosa Bothwelliana and purpurea, both very large; with inflata, princeps, eximia, and gemmifera, in good health. Mr. Jackson also sent a large plant of E. jubata, 4 feet high, and 4 feet through, very fine; a seedling from Shannonii, a good variety; and also ampullacea vittata, in good bloom. Most of these plants were large, and some of the collection a little past their best.—Messrs. Fairbairn, Nurserymen, of Clapham, sent a collection of very prettily grown small specimens: the best of them were jasminiflora alba, ampullacea, a vittata, eximia, cubica major, inflata, Irbyana, Shannoniana, princeps, procumbens, tricolor (Lee's), tricolor elegans, impulsa, sanguinolenta, and the pretty little Savilliana. These plants were in excellent health, and promise to make admirable specimens.—From Mr. Epps, of Maidstone, the plants consisted of tricolor; tricolor (Lee's), a good plant, Savilliana, ventricosa superba, carnea, globosa and rosea, gemmifera, eximia, jubata, jasminiflora alba, inflata, metuliflora bicolor, Templeana, ampullacea, and ampullacea rubra. These, like the preceding, were principally plants in their second year's growth, and had been potted, for the most part, on the "one-shift system."—Another collection of 20 plants was sent by Mr. Green; it contained good plants of elegans and eximia, Cavendishii, ampullacea, Shannonii, ventricosa superba, viridiflora, metuliflora bicolor, tricolor elegans (a fine plant); inflata, Massonii, well bloomed; ampullacea vittata, with Coventryana, parmenteriana rosea, depressa, and jasminoides.—In the groups of 6 plants, Mr. Bruce sent a good specimen of tricolor elegans; princeps, very pretty; Irbyana, viridiflora, ampullacea, and a good plant of eximia.—A Collection, consisting of small plants of E. rubens, viridiflora, ampullacea, Irbyana, eximia, and Jasminoides, was sent by Mr. Doran.—In the Nurserymen's Class, Mr. Frazer produced E. rubens, eximia, Parmenteriana rosea, Irbyana, Westphalingia, and ampullacea superba; Mr. Dawson, of Brixton, a splendid E. Irbyana, Massonii fine, with Savilliana jasminiflora, ampullacea major, and a variety miscalled infundibuliformis. Among others, Mr. Glendinning, of the Chiswick Nursery, had ampullacea vittata, tricolor carnosa, ventricosa brevifiora, pulcherrima, inflata, and ampullacea.

ROSES IN POTS were shown by Mr. Dobson, gr. to Mr. Beck; and Messrs. Lane and Sons, of Berkhampstead. They were not so good as at former meetings, while the kinds were nearly the same; and indeed the pot culture of this popular flower has been confined too much to those kinds which it was known would grow in pots, while those kinds about the management of which there is some doubt have been to a great extent neglected. Another season we hope to see prizes for large collections, and also for (any six plants) of each class of Hybrid China, Gallica, H. Bourbon, Bourbon, Moss, China, Tea, &c. In this manner all the popular tribes will be properly represented, and the cultivation will not, as is the case now to a great extent, be confined to certain popular varieties. The best of the kinds sent by Mr. Dobson were Elise Sauvage, Barbon, General Allard, Queen of the Bourbons, Highclere seedling, resembling Devoniensis, Celimene, and Augustine Mayet. The plants were healthy and clean, but the flowers rather destitute of colour. Messrs. Lane's Collection consisted of Psyche, Charles Duval, Elise Sauvage, Fabvier, Mirabile, Comte d'Osmond, Triomphe de Luxembourg, Napoleon, Duc d'Aumale, Emilie Courtier, Princess de Mecklenberg, Cramoisie superieure, Diana Vernon, Proserpine, Taglioni, and Gouda. Some of Messrs. Lane's plants were not so clean as they might have been, but generally they evinced good management.

Of CUT ROSES, those from Messrs. Paul, of Cheshunt, were the finest, and were exhibited in large groups of a dozen or more flowers, and being placed single had a very fine effect. They consisted of Charles Duval, Jaune Desprez, Bouquet à Flore, Crested Provence, Wm. Jesse, Lamarque, General Allard, Grain d'Or, Madame Deschoulteres, Celimene, Amiable Queen, Icheymaker, Nannette, Acidalie, Emilie Courtier, Félicité perpétuel, Edward Jesse, Eugene Beauharnais, Josephine Malton, Aubernoir, African Black, Duchess of Sutherland, Mrs. Bosanquet, Charles Sir, Niphets, a splendid kind, Madame Nerard, Louis-Buonaparte, Miss Elliot, Devoniensis, Perpetual Rivers, Paul Joseph Augustine Lelieur, Jaune, Comte de Paris, Madame Laffay, Bourbon Queen, Proserpine, Fleur d'Amour, Lady Stewart, Marie de Neria, Pompone bicolor, Enchantress, and Ne plus Ultra.—Messrs. Lane's varieties consisted of the following:—They were fine flowers, and arranged in rows across the box, after the manner of Messrs. Lee at the June *fête*; Devoniensis, General Christiana, Grandissima, Duchess Montebello, Prince de Provence, Blush Provence, D'Angrusseau, Duc de Treyise, Charles Duval, White Globe Hip, Belle de Rosny, Cynthe, Chatelaine, Paul Joseph, Queen, Lafite, La Seduisante, Berryer, Gen. Foy, Boula de Nanteuil, Triomphe de la guerre, Ohl, Eugene Barbot, Bizarre Marbre, Queen of Denmark, Madam Hardy, Lady A. Peel, Duchess of Sutherland, William Jesse, Prince of Wales, Aubernon, Robin Hood, Madame Laffay, and Miss Elliott.—The kinds sent by Messrs. H. and C. Cobbett, Nurserymen, of Chobham, near Bagshot, were William Jesse, Madame Laffay, Nuralba, Royal Provence, Unique Provence, Victor Hugo, Bouquet de Flore, Lady Warrender, Armosa, Acidalie, Madame Desprez, Félicité perpétuel, Village Maid, Madame Marana, General Allard, and Elise Sauvage. The arrangement of this Collection was rather confused, and many of the kinds were overblown flowers.—From Mr. Francis, Nurseryman, of Hertford, were a collection of twenty-five good Roses, consisting of Jaune Desprez, Augustine Lelieur, Rose du Roi, Belle Marie, Lamarque, Madame Laffay, Queen of Denmark, Triomphe de Plantier, Latifolia, Louis-Buonaparte, Madam Newman, William Jesse, General Lamarque, Devoniensis, General Soyez, Leopold, Chatelaine, Beauty of Billiard, Elise Sauvage, Princess Helene, Lady Fordwich, Queen of Bourbons, and Comte de Paris.—Mr. Cripps produced a small collection, and the best flowers were Euphrosine, Nelly, New Village Maid, Triomphe des Dames, Prudence Reeser, Armide, Jaune Desprez, Madame Laffay, Bourbon Queen, Leopold, William Jesse, Lyonnaise, L'Anglaise, La Pactole, Daphne, and La Columbraine.—Moss Roses were produced by Messrs. Lane and Cobbet, but the latter were certainly inferior. Messrs. Lane's consisted of Crimson, Mottled, Crested, Perpetual White, Prolific, Luxembourg, Malvina, White Bath, Common, Eclatante, and Aspasie; and the best of Messrs. Cobbett's were Unique, Prolific, Luxembourg, Blush, and Mousseuse Partout. But few collections of Roses were produced by Ama-

teurs, and some of them were so incorrectly named that we did not take a note of them. The best were from Mr. Slowe, of Bayfordbury Park; and Mr. Buttery, gr. to F. Raymond Symonds, Esq., Norbiton Park, Surrey. Mr. Slowe's consisted of Cerise, Bourbon Queen, Beauharnais, Madame Laffay, Cramoisie superieure, Hymene, Paria, Goubult, Carmine Superb, Elise Sauvage, Gigantesque, Marjolin, Mrs. Rosanquet, and Caroline. Mr. Buttery's comprised Crimson Perpetual, Aimé Vibert, Emilie Courtier, Beauty of Billiard, Queen of Bourbons, Augustine Marjet, Mrs. Rosanquet, Jaune Despraz, Cramoisie superieure, Triomphe de Plantier, Unique, Fabvier, Phœnix, Armoss, Crimson, Madame Desprez, and Euphrosine. —Mr. Wilson, gr. to Lord Howe, at Gopsall, and Alexander Rowland, Esq., also contributed Roses; but their flowers were over-blown, and neither collection contained any very remarkable kinds, which have not been before noticed.—Mr. Cock, of Chiswick, sent some fine Balsams in small pots; and two magnificently-grand Wardian cases were sent for exhibition by Mr. Potts, of Shrewsbury; they were glazed with the finest sheet-glass, and the framework, which was Gothic, was all gilded. We cannot imagine a finer piece of furniture for a drawing-room than one of these cases, nor a finer habitation for plants while in the drawing-room.

We have had so much to say in favour of the excellence of the FRUIT on former occasions, that at the present time we are at a loss for words to express our admiration of it. We might be very concise, and in a few words say it was all excellent, and that would be the truth; but as there was some variety as to the degrees of excellence, we must in justice to the exhibitors enter into a detailed account. In former years it has been necessary to remind fruit cultivators of the importance of their maintaining the character of English gardeners in the fruit department, but this season they have come voluntarily forward and proved how excellent their management is. We were happy to remark among the exhibitors the gardeners of their Majesties the Queen and Queen Dowager.—In the Collections, Mr. Spencer, gr. to the Marquis of Lansdowne, exhibited a number of magnificent Providence and Queen Pines, fine Cannon Hall, Muscat, Black Hamburgh, and Frontignan Grapes, excellent Cabul Melons, with beautifully-coloured and ripened Elruge Nectarines, and Bellegarde and Noblesse Peaches. To this collection the first Prize was awarded, and certainly it was highly deserving of it, for the fruit was perfect.—Mr. Henderson, gr. to Sir George Beaumont, had fine Queen Pines, but not so well swelled as usual; excellent Black Hamburgh Grapes, Melons, with Elruge Nectarines, and Strawberries, and Cherries.—Mr. Dods, gr. to Sir George Warrender, also sent fine Pines, Melons, Black Hamburgh and Muscat Grapes, very good, with Peaches, Nectarines, Cherries, and Currants. —From the garden of J. H. Oughton, Esq., Elm Grove, Roehampton, Mr. Parker produced very good Black Hamburgh, Black St. Peter's, and Muscat Grapes, with magnificent Nectarines and Peaches, and some fine Melons.—Black Hamburgh and Muscat Grapes, and some excellent Melons, were sent by Mr. Bailey, gr. to the Archbishop of York; good Melons, Strawberries, Cherries, Currants, and Golden Harvey Apples in excellent preservation, by Mr. Davis, gr. to J. Disney, Esq.; and a tolerable collection of fruit came from Mr. Peddrick, gr. to H. Pownall, Esq.—The Pines were all good, but the most perfect specimen in the exhibition was a Queen grown by Mr. Hamp, gr. to Jas. Thorn, Esq. This, we were informed by Mr. Hamp, had been grown on the tank system of heating, and certainly the fruit was as fine as could be desired.—Mr. M'Ewen, gr. to Colonel Wyndham, at Petworth, sent very excellent Providence and Queen Pines.—Mr. Parsons, gr. to A. George, Esq., the same; and very superior Providence Pines also came from Mr. Belton, gr. to C. Winn, Esq., of Nostell Priory.—Mr. Sellers, gr. to L. V. Watkins, Esq., had some fine Enviles; Mr. Henderson, and Mr. Dods, gr. to Col. Baker, some fine Queens; and Mr. Gunter and Mr. Wilmot, of Isleworth, sent some very fine fruit.—Mr. Brown, gr. to C. W. Packe, Esq., contributed some good Providence Pines; Mr. Dryden some good Enville and Providence; but the Enville, Providence, and Otaheite Pines from the garden of Lady Rolle, at Bicton, did not maintain the character of that establishment.—Of Grapes, the finest were from Mr. Dytche, gr. to Sir F. Goodricke, and Mr. Hamp; but very admirable fruit, a little injured by packing, was also sent by Mr. Robinson, gr. to A. Sinclair, Esq., of Liverpool; Mr. Ingram, of the Royal Gardens, Windsor, whose sort was called the Royal Albert, and was grown in a pot; Mr. Atlee, gr. to H. Beaufoy, Esq.; Mr. Dods; Mr. E. Davies, gr. to G. Smith, Esq.; Mr. Umpleby, gr. to H. Benyon, Esq., Leeds; Mr. Godfrey, gr. to the Earl of Limerick, and Mr. Parsons. Other Grapes were sent by Mr. Dods; Mr. Wilson, gr. to Lord Howe; Mr. Taylor, gr. to J. Coster, Esq.; Mr. Henderson; Mr. M'Lean, gr. to the Marquess of Downshire; Mr. Smith, gr. to Sir G. Ansley; and Mr. Gibson, gr. to Her Majesty the Queen Dowager.—Of Market Gardeners, very excellent fruit was sent by Mr. Davis, of Barnet; Mr. Wilmot, Mr. Mitchell, of Brighton; Mr. Chapman, of Lambeth; and Mr. Gunter.—In Peaches, some admirable fruit were sent by Mr. Snow, gr. to Earl de Grey; and very excellent Peaches and Nectarines by Mr. Spencer; Mr. Ewing, gr. to O. F. Meyrick, Esq.; Mr. Ferguson, gr. to the Duke of Buckingham; Mr. Fleming, gr. to the Duke of Sutherland; and Mr. Davis, of Oak-hill, Barnet. Some very good Peaches and Nectarines were also sent by Mr. Collins, gr. to E. H. Chapman, Esq.; and Mr. Foggo, gr. the Marquis of Abercorn.—The Melons especially were exceedingly fine; but as no Prize was awarded, we suppose the internal examination did not satisfy the Judges. —Mr. Fleming sent two very fine Cabul Melons, weighing 10 lbs. each; Mr. Mitchell, gr. to Lord Vernon, sent a very splendid specimen of the Hoosanee; and Mr. Spencer, two remarkably fine fruit of the Beechwood. Mr. M'Ewen and Mr. Graham had likewise some good Beechwood; and other good-looking Melons were sent by Mr. Marton, Thames Bank, Pimlico; Mr. Bance, gr. to Dr. Tarleton, Mr. Gibson, and Mr. Fish, gr. to H. Oddie, Esq.—A bunch of the fruit of Musa Cavendishii was from the Garden of the Society; and of miscellaneous fruit, some fine Greengage Plums were sent from Her Majesty's Gardens, Windsor.—Figs, remarkably fine, but unknown, from Mr. M'Ewen; Cherries, by Mr Meyers, of Brentford, Mr. Redding, and Mr. Baxter; and Circassian Cherries, by Mr. Peddrick.—Fastolff Raspberries were sent by Messrs. Youell; and others, nearly as good, by the Hon. and Rev. R. Wilson.—Mr. Stanley, gr. to H. Berens, Esq., sent fine Citrons; and Mr. Caldwell, a remarkably well-grown Orange.—Some fine Myatt's Pine Strawberries were sent by Mr. Redding; Turner's Pine, by Mr. Turner, of Brentford; Apples, well preserved, by Mr. J. Fish; Cherries, by Mr. Jones, gr. to Sir Moore Disney, and Mr. Elliott, gr. to T. B. Boothby, Esq.; Elton and Turner's Pine Strawberries, by Mr. Jones; Citron des Carmes Pears, by Mr. M'Ewen; and some handsome Cucumbers, by Mr. Mills, not sent for competition, grown in his improved pit, heated by Burbidge and Healy's boilers and tank, "in the short period of 20 days from the time of planting."—Gooseberries were sent by Mr. Meyers, of Brentford; and some seedling varieties, by Mr. J. Fish.

We must not omit some beautiful HONEYCOMB, obtained at Dover, in Nutt's boxes, and exhibited by Mr. Geo. Neighbour, of Holborn.

Though not so numerous as at the two former Exhibitions, and the season having been a very long one, the display of PELARGONIUMS reflected great credit upon the growers, for having produced them in such fine condition as to health, and quantity of bloom. In the Amateurs' class of 12 new and first-rate varieties, in pots of 24 to the cast, *the Gold Banksian* in this class was taken by Mr. Stains, whose collection contained the following sorts:—Sunbeam, Roulette, Superbum, Queen of the East, Rising Sun, Alice Gray, Fair Maid of Devon, Duke of Cornwall, Nestor, Wonder of the West, Matilda, and Wonder.—*The Silver Gilt* was awarded to Mr. Cock for Madame Taglioni, Pulchellum, Unit, Juliet, Sylph, Conflagration, Sir R. Peel, Black Dwarf, Symmetry, Laura, Hector, and Jessie.

In the NURSERYMEN'S CLASS the *Gold Banksian* was awarded to Mr. Catleugh, his collection consisting of Rosetta superb, Tpili, Unit, Nestor, Pandora, Queen of the Fairies, Witch, Dara, Symmetry, Victoria, Beauty, and Grand Monarch.—*The Silver Gilt*, Mr. Gaines, Battersea, for Witch, Miss Louisa Stanley, Excelsum, Fair Maid of Devon, Glory of Jersey, Egbert, Rising Sun, Elegans Novum, Madeleine, Albina, White Surrey, and King of Saxony. The two collections of 12 varieties in 12-sized pots, were from Mr. Catleugh and Mr. Gaines; the former taking *the Silver Gilt Medal* for Nestor, Selina, Sapphire, Queen of Fairies, Dido, Lord Mayor, Madeleine, Matilda, Tasso, Armenia, Constellation, and Cyrus superb.—Mr. Gaines received the *Large Silver* for Madeleine, Egbert, Lady Isabella Douglas, Rising Sun, Cid, Antiope, Mabel, Triumphant, Album perfectum, Erectum, Floridum, and Cyrus.

The exhibition of FUCHSIAS was greater than we had seen brought together at any former period, and many fine and magnificent specimens were exhibited; but good as they were, we could not but feel that there was too great a similarity in the colour, and these elegant flowers will never make an effective display, unless the sorts are judiciously chosen, and a watchful regard paid to contrast of colour. Each collection should contain the greatest range of variety the flowers possesses.—The *Large Silver Medal* was awarded to Mr. Gaines, and to Mr. Laing, of Twickenham; the former collection was composed of Decora, Nobilissima, Britannia, Alata, Eclipse, Robusta, Paragon, Eppsii, Champion, Pulcherrima, and Defiance; and the latter of Venus Victria, Eppsii, Dalstoni, Victory, Stanwelliana, Defiance, Bridegroom, Kentish Hero, Insignis, Conspicua arborea, Chandlerii, and Magnifica.—*The Silver Knightian*, to Mr. Ayres, gr. to W. Cook, Esq., Brooklands, Blackheath, for Attractor, Balloonii, Stanwelliana, Epps's Marie, King John, Eppsii, Speciosa, Globosa major, Elegans, Exoniensis, Excelsa, and Duke of Wellington.—*The Same Medal* was also awarded to Mr. Kendall, of Stoke Newington, for Formosa elegans, Venus Victrix, Brockmannii, Eppsii, Stanwelliana, Compacta, Britannia, Defiance, Eclipse, Alata, Victory, and Robusta.—*The Silver Banksian Medal*, to Messrs. Lane and Son, for Laneii, Pulcherrima, Robusta, Defiance, Exoniensis, Magnifica, Fulgens, Paragon, Alata, Britannia, Brockmannii, and Eppsii; and the *same Medal* for the collection from Messrs. Henderson, Pine-apple-place, which contained the following flowers:—Le Chinois, Pulcherrima, Tricolor, Formosa elegans, Rosea elegans, Chauverii, Majestica, Closiot, Eppsii, Defiance, Lady Walsingham, and Venus Victrix.

The Collections of PICOTEES and CARNATIONS appeared to afford general gratification; there was an excellent display of these beautiful flowers, which are unquestionably rising in public estimation. In the Amateurs' Class the *Large Silver* was awarded to Mr. C. Embleton, gr. to T. Barnard, Esq., whose stand contained the following varieties:—Willmer's Prince Royal, John's Prince Albert, Sharp's Gem, Barnard's Mrs. Barnard, and Lady Douro, Dickson's Bride, and Trip to Cambridge, Wildman's Isabella, Burrough's Lady Douro, Robinson's Nottingham Hero, Sharp's Wellington, La Delicate, and Reade's Favourite, Burrough's Mrs. Bevan, Waine's Victoria, Brinkler's Lady Chesterfield, Gidden's Miss Desborough, Teaser, and Vespasian, Hogg's Queen of England, Burrough's Lady Peel, and Mrs. Benyon, Ely's Marquess of Waterford, and Annersley's Sanspariel.—Geo. Edmonds, Esq., Wandsworth, received the *Silver Knightian Medal* for Willmer's Prince Royal, Barraud's Bride, Barderer, and Eclipse, Burrough's Mrs. Bevan, Annersley's Sanspariel and Mrs. Willoughby, Jessop's Sir W. Middleton, Cox's Victoria Regina, Wildman's Isabella, Wain's Victoria, Dickson's Trip to Cambridge, Kirtland's Wellington and Princess Augusta, Wood's Lady St. John, John's Prince Albert, Gidden's Sir R. Peel, Princess Royal, Teaser, and Don Juan, Lady Flower, Garrat's Lady Dacre, Brinkler's Conductor, and Crask's Queen Victoria.—In the Nurserymen's Class, the *Large Silver Medal* was awarded to Mr. J. Dickson, of Acre-lane, whose stand contained as follows:—Barraud's Portia and Cornelius, Sharp's Gem, Criterion, La Delicate, and Agitator, Dickson's No. 10, No. 2, Lady Jane Grey, Charles Stanford, No. 8, and No. 6, Burrough's Mrs. Bevan, Gidden's Vespasian, Hero of Nottingham, Wildman's Isabella, Gidden's Lydia and Teaser, Kirtland's Princess Augusta of Cambridge, Beauty of Reading, Queen Victoria, and Duke of Wellington, Wain's Queen Victoria, and Willmer's Prince Royal.—The 2d Prize, *Silver Knightian Medal*, was awarded to Messrs. Norman of Woolwich, for Ely's Field Marshall, Halliday's Henrietta, Crask's Victoria, Wain's Queen Victoria, Dickson's Trip to Cambridge, Sharp's Gem, Barraud's Bride and Eclipse, Norwich Rival, Barnard's Mrs. Barnard, Wildman's Isabella, Burrough's Lady Flower and Lady Douro, Bennet's Seedling, Garrat's Champion, Woolwich Beauty, Gidden's Vespasian, Lady Dacre, Purpurea elegans, Halliday's Fair Phillis, Sharp's Invincible, Robinson's Duke of Wellington, Lovegrove's No. 5, and Purple Perfection. *Silver Banksian.*—Mr. H. Ward, Woolwich, for Martin's Prince Albert, Gidden's Lady Dacre, Burrough's Lady Flower, and Mrs. Bevan, Green's Queen, Crask's Victoria, Annette, Trude's Queen Victoria, John's Prince Albert, Wilson's Miss Fanny Irby, Brinkler's Lady Chesterfield, Barnard's Mrs Barnard, Martin's Queen of Violets, Willmer's Prince Royal, Sharp's Invincible, and Countess De Grey, Gidden's Vespasian, Burrow's Jim Crow, Seedling, Purple Perfection, Dickson's Trip to Cambridge, Wain's Queen Victoria, Wood's Lord Hitchbrooke; and *the same Medal* to Mr. Willmer of Sunbury, whose collection consisted of Gidden's Sir R. Peel, Miss Desborough and Vespasian, Hufton's Queen of Sheba, Burrough's Miss Jane, and Aurora, Willmer's Queen, Barraud's Portia, Cornelius and Borderer, Dickson's Trip to Cambridge, Brinkler's Fairy Queen, Willmer's Peter the Great, Miss Browning, an Prince Royal, No. 10. Sharp's Cleopatra, Kirtland's Princess Augusta, Trude's Queen Victoria, Ely's Mrs. Horner, Field Marshall and Marquess of Waterford, Hogg's Lady Acland, and Newell's Harlequin. CARNATIONS.—*The Large Silver*, in the Amateurs' Class, was awarded to Mr. Embleton, gr. to J. Barnard, Esq., for Jaques's Iris, Puxley's Prince Albert, Seedling, Snook's Defiance, Cartwright's Rainbow, Dalton's Lancashire Lass, Holmes's Count Paulina, Brook's Flora's Garland, Grey's Mary, Willmer's Amato, Hero of Middlesex, and Conquering Hero, Seedling, Mansley's Beauty of Woodhouse, Wilson's George IV., Squire's Defiance, Soorn's Bloomsbury, Hogg's Colonel of the Blues, Wood's William IV., Maud's Rauston, Ely's Leviathan, Hale's Prince Albert, Barnard's Duke of Roxburgh, and Seedling. In the Nurserymen's Class the *Large Silver* was given to the Messrs. Norman, of Woolwich, for Squire's Defiance, Ely's Lady Ely, Regulus, and John Wright, Shenning's Duke of Cumberland, Willmer's Solander, Defiance, and Conquering Hero, Wilson's Harriet, Martin's Splendid, Hale's Prince Albert, Franklin's Queen of Hearts, Calcot's Juba, Milwood's Premier, and Robert Burns. Bucknell's Ulysses, Count Paulina, Lady Gardener, Cartwright's Rainbow, Beauty of Woodhouse, Strong's Duke of York, Brook's Flora's Garland, Ely's Duke of Bedford, Hugo Meynell.—To Mr. Willmer, of Sunbury, the *Silver Knightian*, for Ely's Jolly Dragoon, Lady Ely, Addenbrook's Lydia, Willmer's Telemachus, Endymion, Solander, Prince of Wales, Duke of York, Conquering Hero, and Hero of Middlesex, Fletcher's Duchess of Devonshire, Cartwright's Rainbow, Jones's Ringleader, Appleby's Prince of Wales, Strong's Duke of York, Mansley's Beauty of Woodhouse, Twitchett's Don John, Pond's Lady of the Lake, Brooks's Flora's Garland, Christian's Excellent, Holmes's Count Paulina, Hogg's Colonel of the Blues, Ashworth's Miss Walker.—*The Silver Banksian*, to Mr. H. Ward, Woolwich, for Hale's Prince Albert, Ward's Sir Geo. Hosie, Calcot's Brutus, Holmes's Count Paulina, Giddens' Sir R. Peel, Puxley's Prince Albert and Queen, Addenbrook's Lydia, Milwood's Premier, Jacques's Iris, Mansley's Euclid, Martin's Splendid, Wilson's Harriet, Strong's Esther, Smith's Mrs. Betts, Hogg's Epaminondas, Dalton's Lancashire Lass, Brooks's Flora's Garland, Lascelles's Queen of Sheba, Rainforth's Gameboy, Irons's Ringleader, Nix's Lady Chetwynde, Bearless, Sir G. Osbgrne, Willmer's Miss Browning.—*Certificate*, to Mr. Willmer, Jun., King's Road, for Parker's Queen of England, Snooks's Defiance, Stone's Venus, Hale's Prince Albert, Willmer's Duchess of Kent, Endymion, Marquess of Anglesey, No. 106, and Solander, Wood's William IV., Creswell's Premier, Holmes's Count Paulina, Bates's Wellington,

Catleugh, for Cartwright's Rainbow, Headley's Defiance, Puxley's Adelaide, Puxley's Gem, seedlings 194, 288, 172, 196, 189, 251, Puxley's Lady Peel, Prince of Wales, Princess Royal, and Prince Albert, Will's Beauty, Lodge's True Briton, Hogg's Lady Rowley, Low's Marquess of Westminster, Jacques's Iris, Hale's Prince Albert, Twitchett's Don John, Catleugh's Lady Broughton, Wakefield's Paul Fry, Strong's Duke of Bedford.

SHREWSBURY.—*Certificates* were awarded to the following Seedlings:—To Mr. Gaines for a seedling Pelargonium named *Duchess of Lancaster*, a clear, bright flower, orange-pink under petals, with a dash of scarlet in the top petals; it opens well and flowers freely—Mr. Kendall for a seedling Fuchsia named *Erecta elegans*, a well-formed variety, bright carmine tube and sepals, and purple corolla—Mr. Willmer, of Sunbury, for a purple Flake named *Mayo*, a flower of good properties; and Mr. Norman, of Woolwich, for a purple Picotee named *Beauty*, a light-edged purple, well-formed, with the colour uniform and unbroken.

COUNTRY SHOWS.

Ayrshire Horticultural Society, June 26.—This was the first Exhibition. The display of flowers was excellent, the Pelargoniums, Calceolarias, and Fuchsias were beautiful, and constituted the greater part of the Exhibition. The Heaths, a class of flowers becoming every year more popular, from Mrs. Hamilton and J. Miller, Esq., were very fine. Among Greenhouse Plants, we observed a specimen of Pimelea decussata, from the garden of Mrs. M'Taggart; it measured 4 feet in height and about 9 feet in circumference, and was covered from top to bottom with flowers. Among Herbaceous Plants was a fine Pentstemon cobæa, from the gardens of M. Hamilton, Esq. *Greenhouse Plants*: Mr. Hunter, for Pimelea decussata, Gesnera reflexa, Erythrina Crista galli, Erica vestita alba, and E. breviflora. *Pelargoniums*: Mr. Hunter, for Witch, Decorum, and a Seedling. *Best 7*: Mr. Hunter, for a Seedling called Medora, Rienzi, Prince Consort, Lord Mayor, Evandine, and Victory. *Herbaceous Plants*: Mr. Galbraith, for Pentstemon cobæa, and a Lilac Hollyhock. *Best 10*: Mr. Hunter, for Cypripedium spectabile, Cypripedium pubescens, Scutellaria media elegans, D. elatior, Delphinium grandiflorum, Calceolaria hyssopifolia, Lupinus polyphyllus, &c. *Fuchsias*: Mr. Galbraith, for Ayrshire Lass, Waverley, Lord Montgomery, Eclipse, Diana Vernon, Criterion, Dentist, Beauty, Field Marshal Macdonald, Complete, Ivanhoe, Queen Victoria, Miss Chalmers, and Angelina. *Cinerarias*: Mr. Galbraith, for Granville, Incomparable, and Royal Blue. *Pæonias*: Mr. Hamilton, for Prince Victor, Mountpensier, and Perfecta magnifica. *Heaths*: Mr. Hunter, for five varieties of Ventricosa. Among extra varieties were a collection of Azaleas and American plants, from Mr. Smith, Mount Oswald Grove. A beautiful display of Gothic, Arabian, and a good Silvine arbores, from Rosslie. Four stalks of Myatt's Victoria Rhubarb, weighing 3lbs. each, from Mr. Mowbray and Messrs. Edgar and Sons. Acacia pulchella, Achimenes longiflora, Botryanthera, Boronia pinnata, and a few fine Calceolarias, from Mr. M'Hamilton. Medals were awarded to Mr. Galbraith for Pimelea spectabilis, and P. decussata; to Mr. Hamilton for Pentstemon tricolorum; to Mr. Hunter for Fuchsia fulgens; to Mr. Galbraith for Fuchsia fulgens multiflora; to Mr. Hunter for Gesnera glabrata splendida, and to Mr. Pollock for Ayrshire Lass Pelargonium.—*Ayrshire Agriculturist.*

Bolington Horticultural Society, June 5.—This was the first meeting for the season. The specimens most worthy of notice were a beautiful Cactus speciosissimus, from S. Needham, Esq., the Rev. Mr. Molyneux's splendid Rhododendron splendens, Sir W. Stanley's Gnidiums, Leschenaults, and Azalea indica. There were a great number of choice Pelargoniums, amongst which, Joan d'Arc and Beauty of Kilve, from H. Littledale, Esq., were much admired. Miscellaneously were good, consisting of Black and White-Grapes, Melons, and Guavas. The following Prizes were awarded:—*Greenhouse Plants*: Dendrobium fimbriatum, Sir W. M. Stanley, Bart. *Stove Plant*: Euphorbia splendens, Rev. J. Molyneux. *Greenhouse Plant*: Azalea indica, Sir W. Stanley. *Pelargoniums*: Joan d'Arc, H. Littledale, Esq. *Fuchsias*: Globosa elatior, S. J. Wainwright, Esq. *Collection of Greenhouse Plants*: 1, Salvia patens, Chatice arborea, Lychnis fulgens, Lytta magnifica, and E. tricolor elegans, Sir W. Stanley; 2, Gladiolus maximus, Achimenes longiflora, Maranta fasciata, Begonia serratifolia, &c., Rev. J. Molyneux. *Pelargoniums*: 1, Desmarestii, Bridesmaid, Vulcan, Lady Douro, Orange Boven, Queen Dowager, H. Littledale, Esq.; 2, Sylph, Louis Quatorze, Cortes, Alexandrina, Corinna, Joan d'Arc, H. Winch, Esq. *Four Dahlias*: 1, Juba, Coronation, Erectum, and Mabel, Sir W. Stanley; 2, Decorum, Beauty of Ware, Barratt's Belgian Queen, Grand Duke, H. Littledale, Esq. *Fuchsias*: 1, trimbles, Pictorius, Mourpensii, Curtisii, Enchantress, and fulgens, Sir W. Stanley; 2, Venus Victrix, Britannia, Enchantress, Chandleeii, and magnifica, J. T. Raynes, Esq. *Verbenas*: 1, Queen, Perfection, Henderssonii, rosea odorata, variegata, and speciosa, S. Wright, Esq.; 2, Ignea, Rubens, Pulchra, Hispida, and Incisa, J. Cubin, Esq. Best *Greenhouse Plant*: Aphelexis humilis, Sir W. Stanley. Best *Stove Plant*: Gesnera Cooperii, W. Sharp, Esq.—*Liverpool Mail.*

Blackburn Tulip Show, June 19.—At a Meeting of the Tulip-growers of Blackburn and its neighbourhood, the following flowers obtained Prizes:—1st *Pan of Six Blooms*, containing Trafalgar, Phœnix, La belle Marinus, Lewold, La belle Annette, and Unique, Mr. T. Chippindale: 2, Trafalgar, Incomparable Bizarre, Violet Winner, Violet à feuil Noir, Duc de Bronte, and Unique, Mr. N. Briggs. *Three Blooms*: 1, Duke of Lancaster, Bien Fait, and Wellworth, Mr. R. Hodgson; 2, Duke of Wellington, Violet Winner, and Hercules, Mr. T. Chippindale. *Breeders, two to each Class*: 1, Arlette, Mr. J. Houlker; 2, Lady Crewe, Mr. W. Hargreaves.—1, Eunota Sophia, Mr. T. Chippindale; 2, Saint Sebastian, Mr. R. Kemp.—1, Duke of Hamilton, Mr. J. Houlker; 2, Charbonier, Mr. J. Houlker. *Selfs*: 1, Min d'Or, Mr. N. Briggs; 2, White Flag, Mr. N. Briggs. *Doubles*: 1, Double Rose, Mr. N. Briggs. *Premier Blooms*: Washington, Mr. R. Kemp. *First Class*: Trafalgar, Mr. N. Briggs; Parton's Liberty, Mr. J. Houlker; Duke of Wellington, Mr. C. Turner; Duke of Lancaster, Mr. T. Chippindale; Surpass Catafalque, Mr. R. Hodgson; Catafalque Superfleurs, Mr. H. Seed; Sir Sydney Smith, Mr. R. Kemp. *Second Class*: Violet Winner, Mr. T. Chippindale; Washington, Mr. W. Hargreaves, Mango, Mr. R. Riding; Maitre partout, Mr. J. Houlker, Demeroc, Mr. R. Kemp; Lautra, Mr. N. Briggs; Ne plus Ultra, Mr. T. Chippindale. *Third Class*: Wellworth, Mr. R. Hodgson; Doolittle, Mr. W. Wilkinson; Lady Crewe, Mr. J. Houlker; Prince Albert, Mr R. Riding; Rose Carnesse, Mr. T. Chippindale; Rose Celina, Mr. R. Riding; Heroine, Mr. R. Hodgson. *Fourth Class*: Abercromby, Mr. J. Houlker; Incomparable Bizarre, Mr W. Hargreaves. Phœnix and Lustre de Beauté, Mr. R. Hodgson, Albion, Mr. H. Seed; Turner's Black Prince, Mr. N. Briggs; Beauté Empereur, Mr. R. Hodgson. *Fifth Class*: Unknown, Mr. R. Hodgson; Rouge de Siam, Bien Fait, and Violet Walters, Mr. R. Ainsworth; Maitre partout, Mr. W. Hargreaves; Prince de Largess, Mr. R. Ainsworth; Fuller, Mr. C. Turner. *Sixth Class*: Rose Unique and Rose Vesta, Mr. W. Wilkinson; Lady Crewe, Mr. T. Chippindale; Roi de Cerise, Mr. R. Ainsworth; Princess Royal, Mr. E. Hodgson; La Vandyke, Mr. W. Wilkinson; Lord Hill, Mr. N. Briggs.

Cambridge Florists' Society, July 26.—Roses were present in great variety. Ranunculuses were but so-so as to bloom, from the wet. Pansies were of good size and fine colour. The following Prizes were awarded:—*Fancy Pansies*: Purple Edged and Spotted: Prince of Wales, Mr. Crisp; Maids of Kent, Mr. Ready; Maid Marian, Mr. R. Headly; Butler, La Vandyke, and Esther, Mr. Catling. Dark Purple Varieties, Mr. Crisp; Superbus, Mr. Ready; Varieties, Mr. Crisp; Black Prince, Superbus and Varieties, Mr. Ready. Yellow Ground: Andromache, Mr. Crisp; Andromache, Mr. Ready; Purple, Mr. R. Headly; L'Arbriseau, Mr. Catling; Grace, Montague and Andromache, Mr. Ready. Rose and Pink: Alice, Rose Unique, Alphonso, Duchess of Richmond, Alphonso and Rose Unique, Mr. Catling. White Edged: Maid Marian, Magdalen, and La Singulaire, Mr. R. Headly; Dorcas, Mr. Ready; Mr. Welch, Mr. R. Headly; La Singulaire, Mr. Catling. Light Purple and Grey: Nomius, Mr. Crisp; Porcia, Amatamut, Othello, Baroness Percy, and Nomius, Mr. Ready. Orange: Cedo Nulli, Orange Brabançon, Prince of Orange, and Orangiere, Mr. Crisp; Black: Condorcet, Navara, and Condoreet, Mr. Catling; Black Prince, Navara, and Kempenfeldt, Mr. R. Headly. Buff: Cox's Buff, Fair Quaker, Colenre de Perle, and Cox's Buff, Mr. Crisp; Red and White Striped: Le Temeraire, Fillet Partuite, Le Temeraire, and Œillet Due, Mr. Crisp. Olive: Bouquet Sansparell, Pherobasis, Harvey's Olive. Jaune on Pompadour, Bouquet Sansparell, and Hortensis, Mr. Crisp. White: La Favorite, Mr Crisp; Pausanias, Mr. R. Headly; White Swan, Snowden, Februn, and Pausanias, Mr. Ready. Yellow ground Edged: Headly's King James, Albion, Nestor, Marshal Key, and Pucello, Mr. R. Headly. Crimson: Duke of Wellington, Mr. Catling; Firebrand, Newton, Maulius, and Firebrand, Mr. Crisp, Duke of Wellington, Mr. Catling. Yellow and Sulphur: Adrian, Mr. Crisp; Eliza and Beroth, Mr. Ready; Sulphurea, Mr. R. Headly; Ghiace, Mr. Crisp; Marquisate, Mr. Ready. Scarlet: Jupiter, Alphonso, and Rising Sun, Mr. R. Headly; Jupiter, Mr. Ready, Rising Sun, and Julius Cæsar, Mr. R Headly. Coffee Colour: Prince George, and Theodat, Mr Crisp; Versailles, Mr. Catling; Pherobasis, Mr. Ready; Prince George, Mr. Catling; Theodat, Mr. Ready. Red and Yellow Striped: Scarlet and Gold, Mélange des Beauté, La Soleil, Scarlet and Gold, and Mélange des Beauté, Mr. Crisp. Shaded White: Princess Charlotte, Tillott's Blush, St. Jerome, Tillott's Blush, and St. Jerome, Mr. Crisp. Mottled: Thompson's Queen, Mr Catling; Seedling, Shell, and Seedling, Mr. R. Headly; Julienne, Mr. Crisp. *Pinks.*—Red lace: Buck's Queen, Mr. Ready; do., Mr. R. Headly; Mrs. Childers and Earl of Uxbridge, Mr. J. Headland; Bond's Seedling, Mr. Ready; Mrs. Childers, Mr. J. Headland. Purple Laced: Duke of Northumberland, Mr J. Headland; Norman's Henry and Hodges's Gem, Mr. R. Headly; Lovely Ann, Mr. Ready; Hodges's Gem and Duke of Northumberland, Mr. J. Headland. Rose Pinks: Wood's Superb and Windsor Castle, Mr. Catling; Wood's Superb, Mr. R. Haylock; Harefield Rose and Anna Boleyn, Mr. Catling; Wood's Superb, Mr. R. Haylock. Plain Pink: Conqueror, Mr. J. Headland; Venus, Parry's Union, Well's Superb, Conqueror, and Parry's Union, Mr. Catling. *Roses.*—Crimson: Boule de Nanteuil, Mr. J. Sparrow; Guerin's Gift, Mr. H. Green; George the Fourth, Messrs. Hudson; Edmund Kean and Grande Cramoise, Mr. Twitchett. Yellow: China Ne Plus Ultra and Smith's Yellow Noisette, Mr. H. Green; do., Mr. E. Harris; do., Mr. H. Green; do., Mr. J. Sparrow. Deep Blush: Claude Duval, Mr. Catling; Browne's Superb, Mr. H. Greene; Provence, Mr. Ready, Crested Moss and Provence Moss, Mr. R. Headly. Striped: Village Maid, Mr. Ready. Light Blush: Triomphe de Guerin, Mr. H. Greene; do., Mr. Twitchett; do., Mr. J. Headland; Fanny Parriset and Maiden's Blush, Mr. Twitchett. Dark: Miraiba and General Lamarque, Mr. H. Green; Thornless Violet, Mr. F. B. Smith; Grand Duke of Tuscany, Messrs. Hudson; do., Mr. E. Harris. White: Blanche Fleur, Mr. J. Sparrow, do., Mr. H. Green; Madame Hardy, Mr. Twitchett; Unique, Mr. J. Kits; Madame Hardy, Mr. J. Sparrow; do., Mr. E. Harris. Crimson Scarlet: Brennus, Mr. H. Greene; do., Mr. J. Headland. Mr. H. Green's Prize to *Amateurs—Pan of Roses*: 1, Blanche Fleur, Village Maid, Fanny Parriset, George IV., Triomphe de Guerin, Provence, China Ne Plus Ultra, Fulgens, and Brennus, Mr. J. Sparrow; 2, Yellow Noisette, Blanche Fleur, Provence, Coronation, George IV., Duke of Devonshire, Beauty of Billard, Duchess d'Angoulême, and Brennus, Mr. J. Taylor. *Pan of Six*: 1, Duke of Devonshire, Crested Moss, Madame Hardy, Edmund Kean, Brennus, and Triomphe de Guerin, Mr. Twitchett; 2, Madame Hardy, George IV., Blanche Fleur, Ne Plus Ultra, Provence, and Duke of Devonshire, Mr. E. Harris. *Pan of Three*: Duke of Devonshire, Provence, and Blanche Fleur, Mr. J. Boning. *Collections of Plants*: 1, Erica mutabilis, Ventricosa superba, and jasminiflora, Spiræa japonica, Petunia superba, Pelargonium tricolor, Vinca rosea, and picta, Oncidium pulvinatum, and flexuosum, Gloxinia speciosa, and rubra, Pimelea decussata, Lantana Sellowii, Sedum cæruleum, Swainsona coronillifolia, Mr. A. Biggs; 2, Pentstemon gentianoides, Petunia, Enchantress, Hydrangea hortensis, Fuchsia fulgens, and multiflora, Clematis florida, Erica ventricosa superba, Pelargonium, Victory, and Garth's King, Rhododendron ponticum, Verbena Thompsonii, Pimelea decussata, Lotus Jacobæus, Azalea odorata, Alstræmeria pelegrina, Leschenaultia biloba, and formosa, Mr. H. Green. *Specimen Plant*: 1, Fuchsia globosa, Mr. A. Biggs; 2, Clematis Sieboldi, Messrs. Hudson. EXTRA PRIZES: Alstræmeria pulchella, Mr. Ready.—*Cambridge Chronicle.*

Cambridgeshire Horticultural Society, June 19.—This Exhibition, like the preceding, was well attended. The following prizes were awarded:—*Strawberries*, 1, Keen's Seedling, Mr. G. Fisher; 2, do., Mr. Cumming. *Melon*, Green Persian, Mrs. R. Foster. *Roses*, 2, Mr. Glinso, for Madame Dubarry, Village Maid, fulgens, Blush Hip, Wellington, George the Fourth, Ville de Bruxelles, Duchesse d'Angoulême, Margined Hip, Las Casas, Duc de Cayes, Blush Moss, Luxembourg Moss, African Black, White Moss, Tuscany, Madame Hardy, grandissima, La Volupte, Blanchefleur, Boula de Nanteuil, perpetual, Antinous, and Brown's Superb; 4, Mr. Green, for Globe Hip, Madame Dubarry, Euphrosayne, Camilen estnes, Amelia d'Abancourt, Kean, Noble, Leo the Tenth, Cyrus, Blanchefleur, Royal Marbled, Brennus, Crested Moss, splendidissima, Marbled Superb, Madame Hardy, Brown's Superb, Duke of Devonshire, Beauty of Billard, Coronation, Ne plus Ultra, fulgens, Antonius; 4, Mr. Green, for Provins Moss, Blanchefleur, Queen of Bourbons, Nelly, Crimson Moss, Kean, Prince Albert, Coronation, Madame Desprez, General Lamarque, Luxembourg Moss, Unique, Miss Chauncy, Bernard, Virgin Rose, Grand Triumphant, Duke of Devonshire, fulgens, Crested Moss, Cyrus, Fulgoria, Fanny Parisot, and Wellington; 3 *varieties*, Mr. Twitchett, for Madame Hardy, Brennus, and Village Maid. *Plants in pots*, 2, Mr. Green, for Hydrangea hortensis, Pelargonium Victory, do. Gaines's King, Pentstemon gentianoides coccineum, Alstræmeria pelegrina, Petunia Enchantress, Petunia Seedling, Petunia Sir Robert Peel, Fuchsia Chandleeii, do. carnea, Azalea odorata, Clematis florida, Erica ventricosa superba, ventricosa, Hartnelli bicolor, Rhododendron ponticum, Lotus Jacobæus, Pimelea decussata, Verbena Thompsonia, and 2 Balsams; 2, Messrs. Hudson, for Clematis Sieboldi, Cactus speciosus, South, and Jenkinsonii, Fuchsia Thompsonia, Calceolaria bicolor, Verbena Queen, Pelargonium Mrs. Maclean, Orange Boven, effulgens, and Bollya heterophylla. *Single Specimen*, 3, Mr. Widnall, for Clematis Sieboldii; Messrs. Hudson, for Cactus speciosissimus. *Fuchsias*, 6 *varieties*, 1, Mr. Widnall, for Erecta, elegans, nobilissima, Frontil, formosa elegans, gault flora; 2, Mr. Green, for fulgens, Curtisii, rosea, elegans, bicolor, Youalii, and elegans rubescha. *Azaleas*, 2, Messrs. Hudson, for Curtisii, globosa-major, and Chandleeii. EXTRA PRIZES—*Roses*, Mr. Ready, for Ne plus Ultra, fulgens, Bronzus, Provence, Unique, Moss, Madame de Flahy, Tuscany, Rarnac Goal, George the Fourth, Village Maid, and Unknown. *Pansies*, Mr. Gimson, for Hannah, Hurst, Orlando, and alba.—*Cambridge Advertiser.*

Colchester Horticultural Society, June 14.—This was the first meeting for this year. It was held in the grounds belonging to the Diocesan College, which are beautifully wooded with Deodars and other rare trees. Several prizes were awarded, but we have only been furnished with a list of rewards without the names of the flowers for which they were given.

Royal Cornwall Horticultural Society, July 9.—This was the second Exhibition. The show of flowers was not equal to that of the previous meeting. Among stove plants were Cattleya Skinneri, and Oncidium flexuosum; several specimens of Achimenes and Rondeletia speciosa. Messrs. Veitch, of Exeter, showed—Hindsia violacea, H. longiflora, Clitoria fulgens, Echites atropurpurea, and Passiflora carnea. FRUIT.—The prizes were awarded as follow:—*Melon*: 1, King's Own Green Flesh, G. C. Fox, Esq.; 2, W. Daubuz, Esq., for the same. *Cherries*: 1, Black Heart, J. Vivian, Esq.; 2, White Heart, Mrs. Sampson. *Gooseberries*: Yellow Rockwood, Mrs. Sampson; green or white Do.: Wainwright's Green Cream, Mrs. Sampson; Do.: red, Wellington, Mrs. Sampson. *Currants*: Knight's Red, Sir C. Lemon, Bart., M.P.; *black Do.*: Naples Black, Sir C. Lemon, Bart., M.P. *Red Raspberries*, Caroline, Mrs. Sampson. *Strawberries*: 1, Old Pine, Sir C. Lemon, Bart., M.P.; 2, Do., 2, Carolina, Rev. C. Rogers. *Cherries*: May Duke, Rev. C. Rogers. *Melon*: King's Own, Rev. C. Rogers. FLOWERS.—*Stove Plants*: 1, Achimenes longiflora, A. grandiflora, Ardisia crenulata, Rondeletia speciosa, Vinca rosea, Ixora, bandhuca, J. P. Magor, Esq.; 2, Euphorbia splendens, Achimenes grandiflora, Vinca oculata, Manettia gonlata, Achimenes longiflora, Vinca oculata rosea, J. Vivian, Esq.; 3, Achimenes longiflora, A. grandiflora, Rondeletia speciosa, Clerodendron splendens, Manettia glabra, W. M. Tweedy, Esq. *Greenhouse Plants*: 1, Oncidium papillo, J. P. Magor, Esq.; 2, Cattleya Harrisonii, G. C. Fox, Esq. *Greenhouse Plants*: Lychnis grandiflora, Scitya salicifolia, Petunia rook's nest, Millia a. punctata, Statice puberula, Viscaria oculata, G. N. Simmons, Esq.; specimen, Deya carnosa, J. P. Magor, Esq. *Pelargoniums*: La Grand, Naualigans, Anna, Atillabey, Ignes de Costa, W. Daubuz, Esq. *Heaths*: Eximia, viridiflora, ventricosa pauguana, and ventricosa superba, G. N. Simmons, Esq. *Fuchsias*: 1, Tricolor, Augusta, Exoniensis, Grovehilli, Richardii grandiflora, Multiflora, J. Vivian, Esq.; 2, Bateali, Magnifica, Exoniensis, Tricolor, Victoria, Splendissima, G. C. Fox, Esq.; 3, Augusta, Curtisii, Middletonia, Richardii grandiflora, Mollypennii, Multiflora, F. Pasmingham, Esq. *Verbenas*: 1, Ovid, Tweediana superba, Lascoti, Queen, Ignea, Odoratissima, Rev. C. Rogers; 2, Queen of Orange, Odoratissima, Bride, Duchess of Cornwall, Seedling, G. N. Simmons, Esq. *Roses*: 1, Smith's Yellow, Fulgens, Indica, Duprez, Hybrid Lamarque, Devonshire, Indica odoratissima, Agaa Maria, Garlandia, Yellow China, King, Gellot, Tea-Bennetts, G. C. Fox, Esq.; 2, Jaune Desprez, Hybrid China, Clara Sylvain, Astrolabe, Common Rose, Smith's Yellow, Celina Rose, Acidalie, Unique provins, Rivers's Purpetual, L'Ingenue, Duc de Choiseul, N. C. Stephens, Esq. *Carnations*: Wood's William IV., Wigg's Earl of Leicester, Ely's Lady Ely, Ely's Col. Wainman, Jacques floriana, Manley's Beauty of Westhouse, F. Pasmingham, Esq. *Picotees*: Sharp's Rector, Martin's Queen Victoria, Purple Perfection, Burough's Miss Jane, Sykes's Eliza, Sharp's Cleopatra, F. Pasmingham, Esq. *Fuchsias*: Pasmingham, Augusta, Venus Victrix, St. Clare, Dalstonii, Corruscopeia, G. N. Simmons, Esq. *Picotees*: Sykes's Eliza, Ely's Bright Venus, Sharp's Duke of Wellington, Cox's Classica, Gaskell's Lady Diana, Wilmer's, Mary Anne, Mr. R. Dunn. *Calceolarias*: Unexceptionable, Decora, Brilliant, Splendens, Gem, Bicolor, W. Daubuz, Esq. *Pelargoniums*: Splendens, Grandiflora, Madonna, Rosea alba, Lady Peel, Gem, F. Pasmingham, Esq. VEGETABLES.—*Peas*: 1, British Queen, W. Daubuz, Esq.; 2, Woodford Marrow, G. C. Fox, Esq. *Kidney Beans*: G. C. Fox, Esq. *Cauliflowers*: Walcheren, F. Pasmingham, Esq. *Artichokes*: Globe, Mr. C. Lemon, Bart., M.P. FLORISTS, NURSERYMEN, AND MARKET GARDENERS.—*Roses*: 1, cut flowers, Rivers's Mystery, Rubbel Mere, Vibren, Isle de Bourbon, Madame Laffay, White China, Perpetual China, Yellow China, Tricolor pompone, Common Moss, Noisette China, Black alcrais, Madame Dubarry, Lord Wellington, Common China, Rivers's Nankin, New Blush Moss, Duchess d'Angoulême, Blush Rose Brunswick, Amy Robsart, Cyrtle, Alinee Vibert, and Blushing Maid. Mr. J. Treseder; 2, Royal Portugal, Duchess d'Angoulême, Grand Agatha, St. Vero, Queen Bourbon, Tuscany, Aimee Vibert, Damask, Triomphe de Flore, Charles X., Ne plus Ultra, General Lamarque, De la Flash Moss, White Rose, Wellington, Blush Moss, Unique, Fimbriata, Village Maid, Fulgens, Caroline, Black African, Luxembourg Moss, Hybrid Bourbon, and Lacepede, Mr. J. Paul.—*From the West Briton, Carnegie.*

Doncaster Horticultural Society, June 26.—This was the second Exhibition. The plants and flowers were much inferior to those of the previous meeting. Dr. Schofield exhibited a fine specimen Sedum acre. Among the nurserymen, Mr. W. Barratt, of Wakefield, sent Lilium speciosum; and from Mr. Milan were several varieties of Achimenes. W. Chadwick, Esq., exhibited a beautiful Thunbergia alata. From Mr. Cooke was Erythrina crista-galli, which obtained the first Prize. The following Prizes were awarded:—*Stove Plant*: G. J. Horsfall, Esq., Gloxinia rubra and speciosa. *Greenhouse Plant*: J. H. Cooke, Esq., Erythrina crista-galli; 2, G. J. Horsfall, Esq., Achimenes longiflora; 3, W. Chadwick, Esq., Crassula coccinea. *Cactus*: 1, G. C. Walker, Esq., Cactus Ackermanni; 2, G. J. Horsfall, Esq., Cactus speciosissimus. *Exotic Climber*: 1, W. Chadwick, Esq., Thunbergia alata; 2, G. C. Walker, Esq., Clematis Sieboldii. *Purple Pelargoniums*: Dr. Schofield, Juba, and Conservative. *Crimson*: Dr. Schofield, Splendidum and Grand Duke. *Rose*: 1, Dr. Schofield, Helen of Troy; 2, W. Chadwick, Esq., Priam. *Pink*: Dr. Schofield, Nymph. *Blush*: 1, W. Chadwick, Esq., Victory; 2, Lady Cooke, Rienzi. *Light clouded*: 1, Dr. Schofield, Jehu; 2, Lady Cooke, St. Leger. *Dark clouded*: 1, H. Cooke, Esq., Firebrand; 2, Dr. Schofield, Jewess. *Scarlet*: Lady Cooke, Superb. *Striped*: Dr. Schofield, speculum metal. *White*: Lady Cooke, Alexandrina. *Zonal*: H. Cooke, Esq., Ventricosa superba. *Fuchsia*: 1, Mrs. White, Exoniensis; 2, Dr. Schofield, Nevonia. *Cinerarias*: Dr. Schofield, Wizard of the North. *Herbaceous Plant*: Dr. Schofield, Phlox omnifolia. *Pansies*: G. Jessett, Esq., Margery Dawson, Beauty of Ritching, Yellow Defiance, Governess, Anna, Black Prince, Sulphurea elegans, Lord Francis Egerton, Sunbeam, Cox's Defiance, and Napoleon. *Six varieties*: G. Jessett, Esq., Regulator, Prince Albert, Lord F. Egerton, Maid of Milan, Fiddy, and Yellow Defiance. NURSERYMEN'S PRIZES.—*Greenhouse Plant*: Mr. Milan, Achimenes grandiflora. *Exotic Climber*: Mr. Milan, Morinda alba.—*Doncaster Gazette.*

Hampstead Florist Society, June 13.—This was the first Exhibition; it took place in the grounds of J. Jackson, Esq. The company was numerous. The following Prizes were awarded:—*Collections*: 1, Mr. Cockburn, gr. to the Earl of Mansfield, for Pimelea decussata, Phillibortia grandiflora, Tropæolum tricolorum, Epacris grandiflora, Anagallis grandiflora rubra, Swainsona albiflora, Cytisus spicatus, Leschenaultia formosa and biloba; 2, Mr. Calver, gr. to J. C. Melville, Esq., for Cactus grandiflorus, Polygala cordifolia, Fuchsia Monypennii and incumiflora; a Petunia, named Beauty; a Brugmansia, Lasea grandiflora; a Calceolaria, named Gem; Mimulus roseus,

and others. 6 *Plants*: 1, Mr. Goulding, gr. to T. Turner, Esq., for Pimelea decussata, Tropæolum tetraphyllum, Epacris grandiflora, Cactus Jenkinsonii and Ackermannii, and a Calceolaria, called Emperor; 2, Mr. Wren, gr. to T. Neville, Esq., for Cactus Jenkinsonii, speciosissimus, and Ackermannii, Pimelea decussata, Erica ventricosa, and Polygala oppositifolia; 3, Mr. Garrod, gr. to R. B. Formby, Esq., for Cactus speciosissimus, Ackermanni, Erica ventricosa superba, tricolor, Cavendishii, maxima, and coccinea; 4, Mr. Tucker, gr. to R. Crofton, Esq., for Pimelea hispida and rosea, Mimulus roseus, Fuchsia Atkinsonii and corymbiflora, and a variegated Polygala. *Specimen Plant*: 1, Mr. Goulding, for Pimelea decussata; 2, Mr. Cockburn, for Cactus speciosus; 3, Mr. Wren, for Cactus speciosissimus; 4, Mr. Tucker, for Fuchsia grandiflora; 5, Mr. Garrod, for Polygala grandiflora. *Fuchsias*: 1, Mr. Goulding, for Joan of Arc; Beauty of Hampstead, Sylph, Beauty of Ware, Rienzi, Jewess, Louis Quatorze, Victory, and a seedling; 2, Mr. Cockburn, for Standard Bearer, Exhibition, Pearl, Fairmaid, Emmeline, Comte de Paris, Victory, Elizabeth, and Novelty; 3, Mr. Garrod, for Climax, Victory, Lady Denbigh, Enchantress, Priory Queen, Joan of Arc, Sir Robert Peel, Comte de Paris, and Rienzi. 6 *Varieties*: 1, Mr. Cruickshank, gr. to J. Jackson, Esq., for Gauntlet, Pearl, Floreus, Una, Britannia, and Madona; 2, Mr. Wrep, for Enchantress, Victory, Sylph, Grand Duke, Alicia, Superba; 3, Mr. Culver, Beauty of Hampstead, Lady Denbigh, Lady Murray, Mr. Stewart, Victory and Priory Queen; 4, Mr. Tucker, Lady Denbigh, Garth's Perfection, Belladonna, Erectus, Jewess, and a seedling. *Calceolarias*: 1, Mr. Garrod, for Royal Standard, Lady of the Lake, Green's Victoria, Salmon King, Thomson's Corymbiflora, and Sir Robert Peel; 2, Mr. Cockburn, for Lady Constable, Royal Standard, Salmon King, Standishii, and two others.

Inverness Horticultural Society, June 20.—The numerous advantages of devoting attention, in the first place, to the higher branches of Horticulture, observed by this Society, are now beginning to develop themselves, with much satisfaction to the acting committee, and great benefit to our northern districts. Many thought that the founders offering prizes at the commencement for the very finest greenhouse productions, which are the subjects of competition at the English Shows was but a foolish imitation of southern practices, and exclaimed that we should be content with mere common garden flowers and vegetables, and should chiefly devote ourselves to the improvement of small steadings and cottage gardens. Amateurs were early encouraged to compete, but it is only now that they are beginning to do so; and for the last three successive years the premiums offered to amateurs have been utterly disregarded, no one being found prepared; either in their premises or gardens, to stand the test of examination. Perfection is only attained by stating at a high standard, and therefore our northern horticulturists very quite right in attempting the best things, and holding out rewards for the finest and newest productions, excepting such only as require stove heat. The consequence has been a very marked and progressive improvement in the character of the show at all of our recent Exhibitions in Inverness, and the gradual elevation of the whole horticulture of the north to a respectable position. Gardening, even on the smallest scale and in the remotest parts of the Highlands, is not now what it was in the days of our fathers: the rearing only of a few snow-drops, Pansies, Monkshood, and Bachelors' buttons, and of "Kale, Skirlet, and pot herbs." This Exhibition was an excellent one, and was graced by the attendance of a numerous and respectable class of visitors. A decided improvement was visible in the mode of culture among all the growers, and several new things were exhibited. The following premiums were awarded: *Pelargoniums.*—1, Mr. W. Dallas, gr., Balmore House, for Life Guardsman, Sylph, Nymph, Bridegroom, Adelaide, and Aquatic; 2, Mr. J. Stephen, gr. to Lady Seymour, for Bright Alicia superba, Comte de Paris, Gabriel's King, Louis Quatorze, and Jewess. Extra prize, Mr. Dallas, for Fuchsia Alicia, Garth's Perfection, Alexandrina Victoria, Rienzi, Sylph, Joan of Arc, Queen of Beauty, Orange Boven, Jewess, Masterpiece, Inquisene, and Duke of Devonshire. *Calceolarias.*—1, Mr. R. Fraser, gr. to E. Baillie, Esq., for seedlings shewn; 2, Mr. R. Rindley, gr. to W. F. Tytler, Esq., for Lady Ruthven, Speciosa, Superba, Magnifica, and two seedlings. *Fuchsias.*—1, Mr. R. Fraser, for F. Candidate, Coloneel, Admiral, and Conductor; 2, Mr. W. Westwood, gr. to J. Stewart, Esq., for Mpnypennii, Standishii, Venus Victrix, and Rosea alba. *Best grown Fuchsia*: 1, Mr J. Ross, gr. to Lady Ross, for F. Insignis; 2, Mr. Westwood, for Greyii. *Cineraria.*—1, Mr. Westwood, for King, Rival King, Royal Blue, and Imperial Blue. *Mimulus.*—1, Mr. J. Bain, gr. to Lord Lovat; 2, Mr. Dallas, for seedlings. *Balsams.*—1, Mr. Bain; 2, Mr. Ross. *Petunias.*—1, Mr. W. Dallas; 2, Mr. Bain; *Verbenas.*—1, Mr. Ross, for the Queen, Burleyana, Unique, Princess Royal, Prince of Wales, and Laconi; 2, Mr. J. Stephen, for Princess Royal, Prince of Wales, Tweedside elegans, Rosea elegans, Victory, and Rosea. *Exotic Plants.*—1, Mr. Ross, for Gesnera bulbosa, Gloxinia candida, G. Priestleyii, Euphorbia splendens, Pimelea sylvestris, and Philibertia grandiflora; 2, Mr. J. Stephen, for Polygala oppositifolia, Pimelea decussata, Elichrysum proliferum, Sollya heterophylla, Rulingtonia hederacea, and Swainsona galegifolia. *Specimen of any Exotic.*—1, Mr. Ross, for Russelia juncea—a splendid specimen, trained on an umbrella-shaped trellis, five feet high, from the top of which it drooped downwards for four feet; 2, Mr. Stephen, for Eperis grandiflora. *Rare Exotic Plant.*—Mr. Ross, for Physolobium subumbellatum—a hardy greenhouse plant from Swan River. *Heaths.*—Mr. Stephen, for Erica ventricosa, v. pregnans, v. stellata and odorata. *Rockets.*—Mr. Westwood. *Herbaceous Plants.*—1, Mr. Ross, for a new species Digitalis, spiræa Japonica, Delphinium Barlowii, D. grandiflorum, Cynoglossum stylosa, Dianthus caryophylloides, Hyacinthus orientalis, Tenula Whitleii; 2, Mr. Westwood, for Allium moly, Lychnis fos-cucculi, Dictamnus ruber, Lathyrus grandiflorus, Achillea tomentosa, Aster tomentosus, Delphinium grandiflorum, and Campanula speciosa. *Irises.*—1, Mr. Westwood; 2, Mr. Ross. *Phlox.*—1, Mr. Stephen; 2, Mr. J. Lawrence. *Pinsies.*—1, Mr. Lawrence; 2, Mr. Westwood. *Double Anemones.*—1, Mr. J. Treasurer, gr., Forres; 2, Mr. Stephen. *Cut Roses.*—1, Mr. Treasurer, for Fabvier, Napoleon, Archduke Charles, and Deschiens; 2, Mr. Macdonald, gr., Newton. *Basket of Exotics.*—1, Mr. Ross, for a fine basket, containing Gloxinias, Pimeleas, Achimenes, Boronias, Cockscombs, Balsams, and Hydrangeas; 2, Mr. Stephen, for a similar basket. *Bouquet of Flowers.*—Mr. Lawrence. *Best kept Apples.*—1, Mr. J. Ross, for Ribston Pippins, and Nonpareil Russets, preserved in sand; 2, Mr. Cameron, gr. to Gen. Cameron. *Cucumbers.*—1, Mr. J. Ross, for two of Weeden's Cucumbers, 24½ inches long, by 14 in diameter; 2, Mr. Grant. *Unforced Cherries.*—1, Mr. Bain; 2, Mr. G. Ross, gr., Bught. *Unforced Strawberries.*—1, Mr. A. Fraser, gr. to J. Thomson, Esq., for Myatt's Pine and Ballieferrie seedling—both kinds were large and well flavoured; 2, Mr. G. Ross. *Peas.*—1, Mr. J. Ross, for Early Charlton; 2, Mr. Bain. *Cauliflower.*—1, Mr. Mackintosh, gr. to J. Mackenzie, Esq.; 2, Mr. W. Mackenzie, gr. to Sir J. R. Mackenzie. *Turnips.*—1, Mr. J. Stephen; 2, Mr. Dallas. *Potatoes.*—1, Mr. R. Fraser; 2, Mr. W. Mackenzie. *Cabbages.*—1, Mr. Ross, for large York; 2, Mr. Fraser. *Lettuce.*—1, Mr. Ross, for Drumhead; 2, Mr. Mackintosh. *Autumn sown Onions.*—1, Mr. Bain; 2, Mr. Ross, for Magnum bonum. The following plants, sent for exhibition, deserve notice, namely, a collection of Seedling Pelargoniums, four species of Gloxinia, specimens of Cucumbers and Myatt's Giant Rhubarb, from Altyre; a fine collection from Holme, containing two very large Hydrangeas in flower, one blue and the other light pink; a seedling Pelargonium; a large healthy plant, in full flower, of Boronia crenulata, &c., Heaths and Calceolarias from Dochfour a large assortment of seedlings from Noble Castle, especially six Calceolarias, one flowered, with Cineria maritima, Schizanthus retusus, &c.; a collection of Rustic and Seedlings from Balgownie Lodge; and some stalks (weighing 24 lbs.) of Myatt's Victoria Giant Rhubarb, from Sprottiswood Cottage Gardens.—*Inverness Courier.* [As consequence of this being the most southerly and remote Horticultural Society in the British Isles, and therefore an unusual interest being attached to its proceedings, we have thought it to depart from the general rule, and insert it at full length, even although the names of all the winning flowers are not given.]

Isle of Wight Horticultural Society, July 3.—This was the first exhibition for the season. The weather being fine, the company was numerous. The collections were not plentiful; but in point of good cultivation, they have not been surpassed at any previous Show. The display of Fruit and Cut Flowers was excellent. The prizes were awarded as follows:—*Stove and Greenhouse Plants*: 1, Mr. E. Barnicle, gr. to J. Percival, Esq., for Rose, Goodlies, Ternera elegans, Rondeletia speciosa, Achimenes grandiflora, Columnea Schiedeana, and Gloxinia rubra; 2, Mr. E. Meehan, gr. to Col. Harcourt, for Lilium Japonicum, Vinca rosea, Vinca rosea alba, Polygala oppositifolia, Achimenes longiflora, and Erica Bartnellii. *Fuchsias*: 1, E. Barnicle, for Champion, Robusta, Nobilissima, Victory, Britannia, Venus Victrix, Laneii, Insignis, Magnifica, St. Clare, Fulgens multiflora, Multiflora, and Grandiflora; 2, E. Meehan, for Enchantress, Tricolor, Venus Victrix, St. Clare, Superb, Admirable Monypennii, Splendida, Princeps, Formosa elegans, Chandlerii, Grandiflora maxima, and Racemiflora. *Roses*: 1, Mr. Barnicle, for Brennus, Charles Duval, Madame Hardy, Venus de Medicis, Columella, Mrs. Elliott, Franklin, Algae Dusart, Attila, Enchantress, Duc d'Aumale, Madame Margat, Gazelle, Cambronne, Emerance, La Volupté, Buffon, Cicero, Cyntie, Kean, La Ville de Londres, Rachael, Great Western, Jaune Desprez; 2, Mr. Meehan, for Bougere, William Tell, Victor Hugo, Aimée Vibert, Contard, Lamarque, Kean, Elegans rosea, Camuzet carnea, Aurora, Duchesse d'Angoulême, Prince Albert, Caroline, General Allard, Odeur d'Amande, Brennus, Plurericus, Moss prolifere, Du Roi, Madame Laffay, Celine, Jaune Desprez, Odorata, and Grandissima. *Balsams*: 1, Mr. Bone; 2, E. Barnicle. *Cockscombs*: 1, Mr. Bone; 2, Mr. Salter. *Seedling Pansy*. Mr. Barnicle. *German Stocks*: Mr. Thompson, gr. to Capt. Johnson. FRUIT.—*Black Grapes*: 1, S. Harcourt, Esq., for Hamburgh; 2, Mr. Jobling, for the same. *Green flesh Melon*: Mr. Thompson, Beechwood. *Strawberries*. 1, I. Vaux, Esq., British Queen; 2, Mr. Jobling, Elton Pine. EXTRA PRIZES were awarded to Mr. Meehan, for Achimenes grandiflora, and to Mr. Jobling, for White Sweetwater Grapes.

Liverpool Horticultural Exhibition, June 29.—The second Show was held in the Botanic Garden. The day was extremely fine, and the Exhibition was good and well attended. The Prizes were awarded as follows:—*Heaths*. 1. tricolor, Humeana, ventricosa superba, v. coccinea minor, v. stellata, and tricolor minor, Mr. G. Cunningham; 2, tricolor, Savileana rubens, vestita rosea, persspicua, and ventricosa, T. Davis and Co. *Fuchsias*: 1, Exoniensis, Magnifica, Frostii, Chandlerii, Youelli, Venus Victrix, Gem, Messrs. Whalley; 2, Magnifica, Venus Victrix, Pulchella, Robertsii, St. Clare, Victoria, Chandlerii, R. W. Preston, Esq. *Calceolarias* Standishii, Willmoreana, Desirable, and 6 Seedlings, Messrs. T. Davis and Co. *Pelargoniums*: 1, Madelina, Nymph, Witch, Rising Sun, Anna, Superb, Vesta, Florence, Coronation, Messrs. T. Davis and Co.; 2 Superb, Duke of Cornwall, Hamlet, Rising Sun, Madelina, Anna, Beauty, Gaines's Prince Albert, and Cerito, Mr. G. Cunningham; 3, Duke of Cornwall, Rising Sun, Flash, Cornish Gem, Comet, Prince of Waterloo, Sylph, Garth's Fanny, Messrs. Whalley. *Best Six*: 1, Madelina, Nymph, Witch, Rebe, Superb, and Jubilee, Messrs. T. Davis and Co.; 2, Alexandrina, Prince of Wales Vivid, Sylph, Lowndes Perfection, Joan of Arc, Messrs. Whalley; 3, Mabel, Queen of Fairies, Sylph, Enchantress, Madelina, Pride of Surrey, Queen Victoria, Messrs. T. Davies and Co. *Stove or Greenhouse Plants*. 1, Lilium longiflora, Cactus Ackermanni, C. Jenkinsonii, Gladiolus roseus, Pimelea decussata, I. Hadwin, Esq.; 2, Plumbago capensis, Achimenes longiflora, Fuchsia Curtisa, Statice arborea, Boronia serrulata, Rosa. Aimee Vibert, H. Winch, Esq.; 3, Vinca rosea alba, Pimelea decussata, &c., O. F. Meyrick, Esq. *Best* 4. 1, Euphorbia splendens, Fuchsia Riccartonii, Statice macrophylla, Mr. Skirving; 2, Rondeletia speciosa, Calceolaria Lady Constable, Achimenes grandiflora, C. Horsfall, Esq. *Single Specimen*: 1, Russelia juncea, O. F. Meyrick, Esq; 2, Combretum purpureum, Mr. Cunningham. *Exotic Orchidaceæ*: 1, Brassia Wrayæ, Oncidium amplatum, Oncidium luridum guttatum, &c., C. Horsfall, Esq.; 2, Oncidium sanguineum, O. Cavendishii, Maxillaria Harrisonii, Stanhopea oculata, Cattleya violacea, O. F. Meyrick, Esq., 3, Oncidium Lanceanum, O. Papilio, J. Moss, Esq.; 4, Oncidium luridum, O. luridum var., Aerides odoratum, C. Horsfall, Esq. *Single Specimen*: Oncidium luridum var., C. Horsfall, Esq *Basket of Plants*, containing Oncidium luridum, Gongora maculata, Petunia Beauty, Achimenes longiflora, &c., C. Horsfall, Esq. *Single Specimen* Phlox van Houtii, Mr. Cunningham. EXTRA PRIZES.—*Pelargoniums*: 1, Alexandrina, Louis Quatorze, Garth's Perfection, Joan of Arc, Priory Queen, R. M. Beckwith, Esq.; 2, Prince of Wales, Nymph, Enchantress, Beauty, Elizabeth, R. W. Preston, Esq. *Fuchsias*: Chandlerii, Triumphans, Riccartonii. Racemiflora, Formosa elegans, Fulgens, Magnifica, Venus Victrix longiflora, Mr. Skirving.—*Liverpool Mail.*

Middleton Pelargonium Show, June 22.—Mr. J. Tottlow obtained the Premium Prize with Conservative. *Dark Varieties*: 1, Conservative, Mr. J. Smithies; 2, Lady Douro, Mr. H. Ogden; 3, Comte De Paris, Mr. S. Page; 4, Corona, Mr. D. Saxton, 5, Clarissa, Mr. H. Ogden, 6, Star of Bethlehem, Mr. J. Lancashire; 7, Sultan, Mr. H. Ogden; 8, Commodore, Mr. S. Page; 9, Arabella, Mr. J. Smithies. *Pink and Blush Kinds*, 1, Grace Darling, Mr. J. Hilton; 2, Masterpiece, and Grace Darling, Mr. J. Tottlow; 3, Lowndes' Perfection, Mr. H. Ogden; 4, Foster's Rose, Mr. J. Lancashire; 5, Sylph and Nymph, Mr. J. Tottlow; 6, Lady Cottam, Shepherd and Jubilee, Mr. D. Saxton. *White Sorts*: 1, British Queen, Mr. H. Ogden; 2, British Queen, Mr. D. Saxton; 3, Annetta, Mr. S. Page; 4, Enchantress and Alexandrina, Mr. J. Lancashire; 5, Lancashire Witch, Mr. J. Smithies.

Middleton Tulip Show.—The Premier Prize for the best Feathered Tulip was won by Mr. J. Holland, with Charles X.; the Premier Prize for the best Flamed ditto was awarded to Mr. J Morton, for Violet Waiters. *Feathered Bizarre*: Catalaque, Mr. T. Hilton; Liberty, Mr. J. Schofield; Trafalgar, Mr T. Hilton; Crown Prince, Mr. J. Jaques; Duc de Savoy and Gold Duers, Col. Lee; Sam Joe, Mr. J. Taylor; Surpass Catalaque, Mr. W. Bentley. *Feathered Byblumen*: Barn Fair, Mr. J. Taylor, Baguet and Grotia, Mr. J. Holland; Guastalla, Mr. J. Schofield; Washington, Mr. J. Morton; La Belle Nature, Mr. L. Ashmole; Toote, Mr. J. Morton. *Feathered Roses*: Do little, Mr. J. Schofield; Heroine, Mr. J. Etches; Lady Crewe, Mr. L. Ashmole; Hero of the Nile, Mr. J. Morton; Duke Brunte, Mr. J. Schofield; Cerise Cuery, Mr. J. Heap; Comte de Vergnies, Mr. J. Morton; Unknown, Mr. J. Heap. *Flamed Bizarre*: Albion, Mr. L. Ashmole; Lustre, Mr. J. Morton; Liberty Mr. J. Smithies; High Careless, Mr. J. Jaques; Surpass Licantique, Mr. L. Ashmole; Duke of Leeds, Mr. W. Bentley; Black Prince, Mr. J. Taylor; Old Licantique, Mr. J. Heap. *Flamed Byblumens*. Violet Walters, Mr. J. Morton; David, Mr. L. Ashmole, Sable Mez, Mr. J. Jacques; Diana Bruin, Mr. J. Taylor; Wurtemburg, Mr. L. Ashmole; Rio de Siam, Mr. T. Hilton; Violet Brown and Grotia, Mr. L. Ashmole. *Flamed Roses*. Unique, Mr. J. Morton; Lady Crewe, Col. Lee; Vesta, Mr. W. Bentley; Lord Hill, Mr J. Schofield; Triomphe Royale, Mr. W. Bentley; Duchess of Newcastle, Mr. J. Schofield; Comte de Virginus, Mr. J. Marsden; Lady Wilmer, Mr. J. Taylor; Dutch Catafalque, Mr. J. Taylor; Unknown, Mr. W. Bentley; Polyphemus, Mr. L. Ashmole; Catharina, Mr. J. Taylor; Baguet, Mr. J. Holland; Seedling, Mr. J. Schofield; Lady Crewe, Col. Lee; Newcastle, Mr. J. Heap; Averard, Mr. W. Bentley. *Selfs*: White Flag, Mr. J. Schofield; Miss Or, Mr. J. Jaques.

Middleton Pink Show.—1st Pan, Mr. J. Scholes, for Duke of St. Albans, Cockington, and Paris Union. 2d Pan, Mr. P. Hodgkinson, for Duke of St. Albans, Sir William, and Overall. 3d Pan, Mr. J. Scholes, for Duke of St. Albans, Criterion, and Paris Union. Medium Pan, Mr. W. Taylor, for Duke of St. Albans, Little Wonder, and Lady Middleton. CLASS 1.—*Purple*, Duke of St. Albans, Mr. J. Clegg; Greenside, Mr. P. Hodgkinson; Admiral Napier, Mr. W. Taylor, Sunarrow, Mr. J. Scholes; Robin Hood, Mr. J. Lowther; Jessie, Mr. J. Etches; Gilliver, Mr. J. Buckley; Rango, Mr. J. Scholes. CLASS 2.—*Red*, Criterion, Mr. J. Hodgkinson, Cockington, Sir William, and Miss, Mr. G. Scholes; Elizabeth, Comet, and Broadnought, Mr. J. Brighton; Paragon, Mr. J. S. Buckley. CLASS 3.—*Black and White*, Overall, Mr. J. Scholes; Beauty of Blackburn, Mr. W. Taylor; Sidewell, Mr. J. Etches; Lady Middlewich, Mr. P. Hodgkinson; Jane Shepherd, Mr. J. Buckley; Paris Union, Paintbox, and David, Mr. J. Scholes.

Morningside Practical Gardeners' Society, June 19.—This was the second Meeting for the season. The following Prizes were awarded:—*Pelargoniums*: Mr. J. Downie, gr. to Gen. Robertson, for Gem of the West, Sylph, Grand Monarque, Conservative, Queen of the Fairies, Glory of Jersey. *Pansies*: Mr. J. Downie, for Daniel Defoe, Finlayson's Black-Eyed Susan, Neil Gow, Robbie, Ossian, Flora M'Donald, Gipsy, Donald, Lawsonii, and Miss Russell. *Tulips*: Mr. J. Young, for Sol de Sion, Claudine, Gaddy's Magnificent, Whittingham's Seedling, Grand Monarque, and Triomphe Royale. *Ranunculuses*: Mr. R. Anderson, gr., Burghmuirhead, for Prince Albert, Princess Royal, Lord Strathallan, Robb's Matilda, Queen Adelaide, and Lady Ann Murray. *Hardy Shrubs*: Mr. J. Fargie, gr. to Mrs. Gregory, for Rubesia hispida, Cornelicum chinense, a pink Laburnum, and a white-flowered Spiræa. *Herbaceous Plants*: Mr. W. Denholm, for Aquilegia grandiflora, Phlox omnifora, Pentstemon argutus, Cheiranthus barbata, Delphinium Barlowii, and Potentilla fragaria. *Chinas. Roses*: Mr. J. Fargie, for Duchess of Kent, Archduke, and Yellow China. *Hose Gourds*: Mr. T. Ovens.—Mrs. J. Gould, gr. Caiaman Cottage, exhibited a fine seedling Cineraria, for which an Extra Prize was awarded. Mr. J. Young sent five flowered stems of a new Purple Ranket, for which an Extra Prize was awarded. And Mr. M. Little, gr., Salisbury Green, exhibited two beautiful plants of Giant Cape Stock, growing to pots, which had also an Extra Prize awarded them. The Prize by Mrs. Finlayson of Kinnesting, for the *Best Three Females*, was gained by Mrs. J. Robertson, with Fair Maid, Shakspeare, and Lady Grosvenor.

Norwich Horticultural Society.—This was the Rose Show, which is always very attractive, and was more than usually so this season. Mr. Bircham has some splendid varieties. They consisted of the following: *Hybrid Perpetual*.—La Reine, Lady Elphinstone, Marquis d'Alton, Arieus, Augustine Mouchet, Anbernon, Clementine Soringe, Comte de Paris, Duchess of Sutherland, Earl Talbot, Lady Alice Peel, Lane, Madame Laffay, Marquis of Boccella, Melanie Corem, Mrs. Elliot, Prince Albert, Prince de Galles, William Jesse. *Bourbon*.—Acteon, Anne Boleine, Comte Crimson Globe, Paul Joseph, Proserpine, Souvenir de Malmaison, Thaiffait, Splendens. *Moss*.—Angelique, Comte Grimaud, Pompone, Unique de Provence, White Bath. *Provence*.—Duchesse, Sylvain, Vaugandoon, Unique. *Hybrid Perpetual*.—Agrand, Berel, Blanchefleur, Emerance, Illustre Brunet, La Volupté, Miss Rivers, Cleopatra, Duchess of Kent, Souplisse, Chenedole. *Gallic*.—Agine Dusart, Antonius d'Ormois, Augusta, Camille Lemoine, Boule de Nanteuil, Brinda, Cambronne, Cyrille, d'Aguesseau, Dr. Dekham, Duchess of Beaudemont, Grandissima, Guerin's Gift, Julie, Kean, Latour d'Auvergne, Madame Hardie, Madame Stolz, Napoleon, Juliet, Phœnicus, Triomphe de Asnieres, Shakspeare, La Splendeur, Lee, Leon des Tenth, Samuel Appleton, Sidwell Chine. —Blairii No. 2, Beauté Rose, Bellone, Chenedole, Charles Louis, Comtesse de Lacepede, General Allard, Gilliny, Louis Prien, Marjolin, Madame Plantier, Sylvanie, Triomphe de Laqueue, Decandolle, Emperor Chelsea, Hippocrate, Julia. *Hybrid Bourbon*.—Charles Duval, Comte d'Hericourt, Western, Henri Barbet, Hortense Leroy, Jane Cazes, Jack Rouge, President Mole, Sylvain. Besides these, Mr. Bircham supplied a collection of Moss Roses, &c. The Fruits were not so fine as several of the numerous ones on former occasions. The Melons were excellent, and there were some fine Keen's Seedling Strawberries, from Mr. Kett. The Vegetables, considering the drought, were good. The following is the order in which the prizes were awarded: *Roses*.—1. Rev. T. J. Blofeld for Fulgens, Crested Provins, Antonelle, Reine de Provins, Brennus, Village Maid, Madame Desprez, Blanchefleur, Lee's Crimson Perpetual, Queen of the Bourbons, Wellington Provins, Beauty of Billiard, Madame Hardy, Velours Episcopal, La Ville de Bruxelles, Coronation, Unique, Belle Marie, Aurora, La Volupté, Oracle de Nôtre, Leon des Tenth, Warratah, Crivalis, Triomphe de Guerin, Chenedole, Bath Moss, Rien ne me Surpasse, Fanny Parisot, General Allard, Sapharine, Illustre Beauté, Madame Dubourg, Smith's Rolling Noisette, Grilny; 2. Rev. C. Fellowes, for Charles Duval, Duke of Cambridge, La Ville de Londres, Boule de Nanteuil, La Volupté, Blairii No. 2, Triomphe de Laqueue, Las Casas, Duboury, Rose Major, Blanchefleur, La Ville de Gand, Josephine Lelieur, Belle Marie, Chenedole, Coupe d'Hebe, Belle d'Irvies, Victor Hugo, Princess Helene, Warratah, Grilony, Charles-Louis, Fulgens, Triomphe de Brabant, Belle Parabere, Le Grandeur, Vandael, George IV. Sir Robert Peel, Colonel Fabvier, Mrs. Rivers, Kleber, Striped Unique, General Bernard, Félicité, Hybrid d'Ecouse. *Collection of* 24.—Rev. C. Fellowes, for Blairii No. 2, La Ville de Londres, Las Casas, Kleber, Striped Unique, Triomphe de Laqueue, Cynthie, Leonel Dumonstier, Duke of Cambridge, Coupe d'Hebe, Boula de Nanteuil, Guerin de Denac, Hybrid d'Ecouse, Blush Moss, Legouvé, General Bernard, Ancelin, Rosa Magna, Le Grandeur, Theresita, Fontaine, Itiego, Aspasie, Victor Hugo. *Collection of* 48. —Rev. J. Burroughes, for Petit Pierre, Countess Lacepede, Madame Laffay, Madame Desprez, Louis-Philippe, George IV. Coccinea superba, Madame Plantier, Rose Devigne, Grifiamme, Ecosse, Marshal Soult, Moss Kean, Madame Hardy, Triomphe d'Angers, Las Casas, Bouquet de Flore, Village Maid, Duke of Devonshire, Aurora, Boula de Nanteuil, Grand Perpetual, Rivgo, Sapharine, Ville de Londres, Brennus, Félicité, Blush Moss, Beauty of Billiard, Lee's Perpetual, Perox, Belle Marie, Velours Episcopal, Cleopatra, Becquet, Triomphe de Guérin, Louis-Buonaparte, William Jesse, Emerance, Pashot Provine, La Volupté, Globe White Hip, Striped Unique, Crimson Moss, Ancelline, Iberia, Augustine Lelieur. *Collection of* 18.—Mrs. Blofeld, for Hoveton, Catele, Duchesse d'Orleans, Rien ne me Surpasse, Velours Episcopal, Madame Hardy, Reine de Provins, Brennus, Comte de Paris, Brennan, Superb, Belle Marie, Petit Pierre, Beauty of Billiard, Crested Provins, Blush Hip, Bath Moss, Letitia, King, Triomphe d'Angers. *Collection of* 12.—Rev. J. Burroughes, for Boula de Nanteuil, Sapharine, Las Casas, Comte de Paris, Paul Perrot, Charles-Louis, La Reine, Madame Laffay, Striped Unique, Charles Duval, Miraire Meuble. FRUIT.—*Pine*: Mr. Walton, gr. to R. Sanderson, Esq., M.P. *Grapes*: Black Prince, Mr. Rippingale; Constantia, Mr. J. Potter; Black Hamburgh, pot culture, Mr. Walton. *Melons*: Duncan's Improved, Mr. Excelly, gr. to H. Birkbeck, Esq., Scarlet China, and Casawba, Mr. Rippingale. *Strawberries*: Keen's Seedling, Mr. Aldborough, gr. to G. S. Kett, Esq.; Bath Scarlet, Mr. Spence, gr. to Sir W. B. Proctor, Bart.; Bishop's seedling, Rev. J. Burroughes, Elton Pine, Mr. Scarlett, *Cherries*: Black Tartarian, Mr. Short; May Duke, Hon. and Rev. R. Wilson. *Apricot*: Early Masculine, Mr. Wighton. *Red Cur-*

rants: W. Gale, gr. to H. N. Burroughes, Esq.; Mr. Wood's Currants: Mr. J. Potter. *Apples*: Ribstone Pippin, Mr. Beaurfit, gr. to Mrs. Rutt. *Vegetables*.—*Cucumbers*: (Black Spine) Extra Prize, Mr. Rippingale. *Lettuces*: Cos, Mr. Hamblen; Rev. R. Wilson; and Cos, Mr. Short, gr. to H. Mc Burroughes, Esq., M.P. *Peas*: Auvergne, John Kitson, Esq., Imperial, Mr. Spencer. *Beans*: Long-pod, Mr. Shore. *Potatoes*: King Pippin, Mr. Short. *Cabbages*: Imperial, Extra Value, Mr. Short. *Onions*: Early Tears, Mr. Colman. *Rhubarb*: Myatt's Victoria, Mr. Short.—*Vermil. h Mercury.*

Nottingham Floral and Horticultural Society, June 19.—This was the second Exhibition. Two plants, generally speaking, were in excellent condition. The Pelargoniums added much to the splendour of the show. The Fuchsias were numerous; and attracted much attention, well-grown specimens of that beautiful plant collectively the greater part of the Mixed Nurserymen's Collections. The Roses were magnificent. Upwards of 1100 persons attended the Exhibition. *Ranunculuses*: 1, Mr. Taylor, for Ann (Seedling); La Tempete, La Singulaire, Orion, Virginale, and Socrates; 2, to 5 Model of Socrates, La Daniel, Bridesmaid, Mr. Welsh, Gillatt, Rosey, Groom's Eliza, and Virginale. *Roses*.—Mr. S. R. P. Shilton, for Duc de Choiseul Poiteau, Reine de Provins, Wellington, Spectabilis, Malvina, Madame Duplay, Gazelle, Fontenelle, Duc d'Enghien, L'Ingenue, Duke of Devonshire, Rivet, Beauty of Billard, Coup d'Hebe, Lafouve, Duc de Luxembourg, Miami Nemerion, Felicite, La Remarquable, Painted Lady, La Ville de Bruxelles, Crimson Perpetual, and Bernard. *Nurserymen's 24 Blooms*: 1, Mr. Pearson, for Charles Duval, Rivet, Aequale, Madame Harty, William Jesse, Rose du Roi, Lilac Queen, Blanchefleur, Pourpelle, Countess de Lacepede, Created Moss, Luxembourg Moss, Bath White, Reine des Belges, La Casse, Malmaherey, Antiopus, La Grandeur, Velours Epicopal, La Majestueuse, Carlist, Rigo, Beauty of Waltham, and Vandael; 2, Mr. Prettingham, for Madame Harty, Duke of Devonshire, Caroline, Elizabeth Prior, Charles Duval, Las Casas, Brennus, Crested Moss, Blanchefleur, Antiopus, Victory, Miss Isaacs, Richelieu, Coup d'Amour, Belle de Zibles, Queen's Gift, Aspasie, D'Aogers, La Cerise, Jo Bieke, Commissaire Amy Reboart, and two unknown. *Amateur's 12 Blooms*: 1, Mr. W. Gosse, for Rivet, Armeau, Rose du Roi, Perpetual, Belle Parabere, Bernard, Reine de Rose, Duke gown, Omia Superb, Duke of Devonshire, Fulgens, and Crimson Moss; 2, Mr. Taylor, for Fulgens, Nepius Ultra, Triumphe d'Angers, Brown's Superb, Lilac Queen, Velours Episcopal, Capel, George the Fourth, Tuscany, Old Miss, Charmante Jaune, and Old Cottage; 3, Colonel Wildman, for Auberon, Madame Laffay, Anthonia, Rosse Inebe, Delmon, Camper Corse-fusca major, Eugene Hardy, celestia, and White Ranunculus. *Geraniums*: Reine de Perenes, Mrs S. R. P. Shilton. *Moss*: Gastemoyen, Mrs S. R. P. Shilton. *Fuchsias*: Aspasie, Mr. Pearson; 2, Madame Dubourg, Mr. S. R. P. Shilton. *Tree Fuchsias*: Mr. Pearson; 2, Mr. S. R. P. Shilton. *Pelargoniums*.—*Amateurs*: 1, Mr. F. Nevill, for Ann, Felipse, Maegrath, Magdala, Geneva, Julia, Miltern, Agnes, Black Prince, Hinda, Agnes, Rival Yellow, Emily, and seven seedlings; 2, Mr. S. R. P. Shilton, for Maid of Lodi, Climber, Mungo Park, Curlon, Regulator, Prince Albert, Black Prince, Eclipse, Telleraft, Coronation, St. Paul, Jewess, Hinda, wedding Warrior, Burgundy, Juliana, Regent, and Nestor. *Nurserymen*: Mr. Pearson, for Comet, Milton, Zelica, Black Prince, Elizabeth, Hindon, Agnes, Eulbotica elegans, Macgrath, Paul Jones, Debuck, Sobieski, Atlantes, and Grand Duke. *Pelargoniums*.—*Amateurs*: 1, G. Walker, Esq., for Pictum, Nymph, Joan of Arc, Duke of Cornwall, Crimpee Royal, and Kreutzma; 2, W. Carlage, Esq., for Victor, Joan of Arc, Nabel, Fairy Queen, Duke of Cornwall, and Conservative. *Nurserymen*: Mr. Pearson, for Enchantress, Priory Queen, Comte de Paris, Beauty, Rarnet, and Marianne. *Best one*: 1, G. Walker, Esq., Conservative; 2, Mr. Pearson, Sylph. *Show Pinks*.—G. Walker, Esq., for Illimous rosea, Achimenes grandiflora, and Vinca rosea alba. *Best one*: G. Walker, Esq., Rondeletia speciosa. *Orchideæ*.—G. Walker, Esq., for Aerides affine, Epidendrum aromaticum, and Oncidium flexuosum. *Best one*: G. Walker, Esq., for Miltonia spectabilis. *Greenhouse Plants*: 1, G. Walker, Esq., for Russia juncea, Humea elegans, Pultenæa grandiflora, Sollya linearis, Boronia serrulata, and Erythrina crista galli; 2, A. Lowe, Esq., for Tropæolum pentaphyllum, Boya carnea, Leptospermum Baudeverdi, Russelia juncea, Euphorbia splendens, and Erythrina crista galli. *Best one*: 1, A. Lowe, Esq., Cactus speciosissimus; 2, G. Walker, Esq., Scutellaria splendens. *Calceolaria*: A. Lowe, Esq., for Stamford, Lady Constable, Leopard, Perfection, and Defiance. *Best one*: A. Lowe, Esq., for Prince of Wales. *Brica*: G. Walker, Esq., for Ventricosa superba, Ventricosa speciosa minor, and Rubra calyx. *Best one*: A. Lowe, Esq., Jacqualiflora. *Fuchsias*: 1, A. Lowe, Esq., for Formosa elegans, Blairwelliana, Cyanea arborea, Tricolor, Lanei, and Defiance; 2, G. Walker, Esq., for Venus Victrix, Tricolor, Vera, Formosa elegans, Mons pictus, and Exemplaris. *Herbaceous Plants*: 1, Mr. Pearson, for Aster alpinus, Aconitum stramdiflorum, Dictamnus rubei, and Iris cærulea. *Miscellaneous Collections*.—A. Lowe, Esq., for Fuchsias, Majestica, Fulgens multiflora, Paragon, Mauypennii, Beswateri, Floribunda magna, Champion, Invincible, Britannia, Cameo, Tricolor, Globosa, Lee's Dark, Fulgens style-a quamina, Eclipse, Victory, Rotunata, Defiance, Venus Victrix, Candidati, Pulcherrima, Delicata, Fulgens insignis, Nobilissima, Exquisita, Alata, Rosea alba, Mirabilis, and Rappii; Cameron Gouperii, Calceolarias: Lady of the Lake and Vivid; Leptospermum scoparium; Citrus vulgaris; Swainsona galegifolia; Lantana crocea and sculosta; Gladiolus cruentus; Pinckea decumana; Mesembryanthemum Barclayanum and alba; Campanula garganica; Salvia patens; Russelia juncea, Cineraria; King of Prussia and Carnaine, Petunias: Alice, Enchantress, Cupid, and Magicum. *Verbenas*: Meeke and Red Rover; and Petargoniums: Sylph, Lady Downe, and Lowe's Fiske M'Ivor. Extra Prizes.—*Mesembryanthemum*: Mr. S. R. P. Shilton. *Balsams*: G. Walker, Esq. *Petunias*, A. Lowe, Esq., for Lowe's Alice, Punctata, Cupid, Dædalea, Magician, Enchantress, and Comet. Fuchsia, *Pine*, (Jamaica,) J. Milnes, Esq. White Gobpea, (Mauve,) J. Milnes, Esq. *Strawberries*, (Keen's Seedling,) A. Lowe, Esq. Vegetables.—*Peas*, (Fillbasket) A. Lowe, Esq. *Broad Beans*: 1, (Mazagan,) Lois, Wellington, 3, (Early Long Pod,) G. Walker, Esq. *Rhubarb*, (Victoria,) Mr. S. R. P. Shilton. *Cucumbers*, (Tripoli,) F. Wright, Esq. *Potatoes*, (Early Globe,) Mr. S. R. P. Shilton. *Brace of Broccoli*, (Mallard's Late,) G. Walker, Esq. *Brace of Cabbage*, (Nonpareil,) A. Lowe, Esq. *Brace of Lettuce*, (Both Cos,) F. Wright, Esq. *Brace of Cucumbers*: 1, (Manchester,) G. Walker, Esq.; 2, (Walnut,) Mr. Lincher. *Turnips*: 1, (Stone,) F. Wright, Esq.; 2, (Early Dutch,) A. Lowe, Esq. *Carrots*, (Altringham,) F. Wright, Esq.; and *Shallots*, Rev. S. Lowson.

Pontefract Floral and Horticultural Society of Ireland.—This was the first Show. Roses excellent. The following is a list of the prizes awarded:—*Roses*, 1, 11, M. Dombrain, Esq.; 2, Mr. Bennett; 3, Mr. Rose; 4, Mr. Hall; 5, Mr. Dombrain; 6, Mr. Bennett; 7, Mr. Hall; 8, Mr. Dombrain; 9, Mr. Bennett; 10, Mr. Hall; 11, Mr. Dombrain; 12, Mr. Bennett. *Fuchsias*: 1, Mr. Hall; 2, Mr. Bennett; 3, Mr. Hall; 4, Mr. Bennett; 5, Mr. Hall; 6, Mr. Bennett; 7, Mr. Hall; 8, Mr. Bennett; 9, Mr. Hall; 10, Mr. Bennett; 11, Mr. Hall; 12, Mr. Bennett. *Geraniums*: 1, Mr. Hall; 2, Mr. Bennett; 3, Mr. Hall; 4, Mr. Bennett; 5, Mr. Hall; 6, Mr. Bennett; 7, Mr. Hall; 8, Mr. Bennett; 9, Mr. Hall; 10, Mr. Bennett; 11, Mr. Hall; 12, Mr. Bennett. *Pelargoniums*: 1, Mr. Hall; 2, Mr. Bennett; 3, Mr. Hall; 4, Mr. Bennett; 5, Mr. Hall; 6, Mr. Bennett; 7, Mr. Hall; 8, Mr. Bennett; 9, Mr. Hall; 10, Mr. Bennett; 11, Mr. Hall; 12, Mr. Bennett. *Verbenas*: 1, Mr. Hall; 2, Mr. Bennett; 3, Mr. Hall; 4, Mr. Bennett; 5, Mr. Hall; 6, Mr. Bennett; 7, Mr. Hall; 8, Mr. Bennett; 9, Mr. Hall; 10, Mr. Bennett; 11, Mr. Hall; 12, Mr. Bennett. *Petunias*: 1, Mr. Hall; 2, Mr. Bennett; 3, Mr. Hall; 4, Mr. Bennett; 5, Mr. Hall; 6, Mr. Bennett; 7, Mr. Hall; 8, Mr. Bennett; 9, Mr. Hall; 10, Mr. Bennett; 11, Mr. Hall; 12, Mr. Bennett. *Calceolar

tale respecting whom was founded on some circumstances connected with a shipwreck on the 'Ile d'Ambre,' near Mapou, which were embellished by the author of the tale. On the borders of a shady part of the road near Pamplemousses, the beautiful orange and white varieties of Thunbergia alata were growing, much in the manner that Ground-Ivy grows in England; and by the side of a brook, there was a species of Papyrus or Paper Reed; and a remarkable Palm from Madagascar, from the fibres of which beautiful cloth, resembling muslin, is manufactured. The country between Port Louis and Pamplemousses is grassy, nearly flat, and but little cultivated, up to the foot of the mountain ranges of the Peuse, Moka, and Peter Bot. Beyond the village, the country is more undulating. Much of it is covered with fragments of vesicular basalt, among which the Sugar-cane is cultivated. In many of the fields, the stones are collected into ridges, about four feet apart, and in others, into squares; the canes are planted in the interstices between these rude walls. Some of the stones are small and others as large as a man's head, but the soil among them is adapted for the growth of the Cane, which thrives even in the fissures of the rocks, where the stones preserve it from drought. In some places there are also fields of Manioc, and plantations of Bananas, &c. In others the wood has not been cleared, and among it are many trees of Ebony, *Diospyros Ebenum*; also Custard-Apples, Guavas, &c. that have become wild."

Again, in speaking of the Botanic Garden of Port Louis, the author says—

"We accompanied our friends George and Jane Clark in a ride to Pamplemousses, and spent a little time in the Botanic Garden. This institution is not so well kept up under the English Government as it was under the French; but it contains an extensive collection of trees, shrubs, and herbaceous plants from various parts of the world. The assemblage of stately Palms is very fine, and there is an interesting group of trees and shrubs producing spices, such as Cassia, Cinnamon, Cloves, and Nutmegs. The fruit of the last is something like a Green Chissel Pear; when ripe, it splits open and exposes the Nutmeg enveloped in a coating of bright-red Mace. A specimen of the tree affording the poison used in the Ordeal, in Madagascar, by which great numbers of human beings are annually destroyed, is also preserved in this garden."

We have the following graphic account of the "Ravenala," and some other plants.

"The Travellers' tree, *Urania speciosa*, forms a striking feature in the prospect. Clumps of these trees, composed of several stems, rising from the same root, are scattered over the country, in all directions. The trunks, or more properly root-stocks, which are about three feet in circumference, sometimes attain to thirty feet in height; but whether of this elevation, or scarcely emerging above ground, they support grand crests of leaves, of about four feet long, and one foot wide, but often torn into comb-like shreds. The head is of a fan-like form, and the flowers, which are not striking for their beauty, are white, and produced from large, horizontal, green sheaths. The foot-stalks of the leaves, which are somewhat shorter than the leaves themselves, yield a copious supply of fresh water, very grateful to the traveller, on having their margins cut away near to the base, or forced from contact with those immediately above them, especially those about the middle of the series. The root-stock is of a soft cellular substance, and the fruit, which resembles a small Banana, is dry, and not edible. This remarkable vegetable production is said to grow in the most arid countries, and thus to be provided for the refreshment of man in a dry and thirsty land. Probably the water may originate in the condensation of dew, and be collected and retained by the peculiar structure of the leaf; it has a slight taste of the tree, but is not disagreeable. The Badamier, *Terminalia Badamia*, a handsome tree, with large, obovate leaves, and fruit, the size of an Almond in its husk, abounds in this direction. The spongy shell is so tough as to render access difficult to its small kernel, which is like a young Hazel-nut in flavour. A species of Cinnamon, *Laurus cupularis*, forms a handsome bush in the borders of the woods. I also noticed a species of Mimusops, forming a small tree, with a fruit the size of a nonpareil Apple.

"The Mango, *Mangifera indica*, which was introduced into this island, had become naturalised here, along with several other fruit trees, such as the Apple-fruited Guava, *Psidium pomiferum*, and the Jamrose, *Jambosa vulgaris*. The Pine-apple, *Bromelia Ananas*, forms impassable thickets: its fruit is sold for a few pence at the bazaars. *Gloriosa superba*, or an allied species of this beautiful plant, of the Lily tribe, was growing in an elevated wood, by the side of a streamlet, on the borders of which *Andromeda salicifolia* formed a considerable tree. Numerous species of *Pandanus*, or Screw-pine, Ferns, climbers of the Convolvulus tribe, some of which were very beautiful, and many other interesting plants, were also growing here. Twice, in the course of my walk, my hat came in contact with the naked combs of a large ochre-coloured wasp, which suspends its nests in the bushes. As soon as the buzz of the enraged insects apprised me of the injury I had committed, I hastened through among the bushes, without looking behind, and the return of the twigs drove the wasps back; but on the second occasion, a briery branch caught me by the sleeve, and detained me till one of my antagonists had avenged itself by stinging my finger. The sting is about equal to that of an English wasp; the burning pain subsided in a few minutes, on sucking out the poison, and sucking the part affected. The poison was distinctly alkaline. The Creoles eat the larvæ, or grubs, which they roast in the combs; in taking the nests, they drive off the wasps by means of a burning rag fastened to the end of a stick. The combs are sold in the bazaar at Port Louis. On the muddy margins of a salt-water bay, there are two arborescent species of *Erythrina*, or Coral-tree, the pea-like flowers of which are crimson-red; *Hibiscus tiliaceus*, *Thespesia populnea*, trees with leaves like the Lime-tree, and yellow flowers, with crimson eyes, resembling those of the Hollyhock; *Rhizophora mucronata* and *Bruguiera gymnorhiza*, Mangroves of Laurel-like figure, with large seeds, emitting thick roots while hanging to the tree. To the south of Mahébourg, in a similar association, is the silvery-leaved *Edwardsia dasudata*, with yellow, pea-like flowers, possibly the same as that on Moreton Island, New South Wales, where, also, several other plants similar to those growing here are met with. In a brook that discharges itself into the Rivière des Créoles, a large, smooth, black Neritina was adhering to the rocks."

An account of the mountain vegetation of the Isle of France must, for the present, conclude our extracts.

"We walked to the top of the Pouce, and enjoyed the various beauties and curiosities of creation, presented in the primeval forest of the upper part of the mountain; in which, however, many exotic trees and shrubs have now become naturalised; among these are the Lemon, Guava, Jambos, Date, &c. The Bigarade or Seville Orange, *Citrus vulgaris*, is considered native here. The top of this mountain is 2639 feet above the level of the sea. The ascent is along the rocky and woody side of the glen, at the lower end of which Port Louis is situated. A footpath winding along the rocks, passes nearly over the summit, to the vale of Moka, and saves more than six miles of the distance, the high road winding round the end of the mountain. This footpath is chiefly travelled by Blacks, formerly slaves, now apprentices, who carry great loads on their heads, to the bazaar of Port Louis. The heartless cruelty of systematic oppression, the offspring of slavery, does not allow them to wear shoes to defend their feet, though they generally require sticks to steady their steps among the rocks. The vegetation of the upper part of the mountain resembles that of the mountain tract about Cure Pipe. Similar tree Ferns and species of Pandanus are here, and epiphytes, of the Orchis, Fern, and Pepper tribes, grow on the trunks of the larger trees. In the shady parts of the forest, there are several species of Club-moss, *Lycopodium*, some of which are of the section of the genus to which *L. helveticum* belongs. The apex of the mountain is almost too narrow to stand upon, and the sides and front are nearly perpendicular. At this point we found the pretty little blue *Lobelia serpens*, and a plant of the Heath tribe, *Salaxis arborescens*, the last of which cheered us, by bringing to recollection its British allies, not having seen anything so like an English Heath for nearly seven years. *Rhipsalis mauritiana*, and *Sarcostemma mauritiana*, leafless, fistiform plants, with green stems, the thickness of a quill, were growing upon the rocks midway down the mountain: the former is allied to the Cactuses of America, and the latter has congeners in Africa and New South Wales. Here are also great numbers of large snails, with oblong shells, mottled with brown and white. These snails are eaten by the Blacks, and the shells are sent to England, to decorate the mantle-shelves of the curious."

The lovers of Natural History will find a large field of interesting facts in the remainder of this volume, from which we purpose to borrow from time to time.

Miscellaneous.

New Facts respecting Trees killed by the Effect of Paint and Oil.—In the Number of last March, page 572, we mentioned the loss of a great many fruit trees from the effect of paint. A gardener of Châlon-sur-Saône declared, at a meeting of the Horticultural Society of this town, that, having nailed up some Peach and Apricot-trees upon a trellis freshly painted with verdegris, towards the end of June, in a short time they all died, except one Apricot-tree, which only lost the branches which were attached to that part of the trellis that had been painted. Another gardener reported also that, having rested some bars of wood painted with verdegris upon some Pear-trees, he observed that deep cancer suddenly formed wherever the paint had left any marks. A gardener from the department of Haute-Marne, M. Delisle, wrote to us, saying he had seen trees die from oil which had been spread upon the branches to destroy the caterpillars. The use of soft soap, of which oil is the base, says this gardener, has caused the branches of trees which have been rubbed with it to die.—*Revue Horticole.*

CALENDAR OF OPERATIONS
For the ensuing Week.

I.—HOTHOUSE CONSERVATORIES, &c.

Before advancing farther, let us assert in if those stove-plants which we have lost, or found difficult to manage in former winters, are now in a state likely to give less trouble during next winter; examine their pots, and if the soil or drainage is not in a proper condition, shake the mould away from the roots, and re-pot them in light soil. Sandy-loam is better for wintering delicate stove-plants in than composts containing either peat or leaf-mould; peat is very liable to get saddened in a close stove in winter, but in frames and greenhouses nothing suits better. In the beginning of the growing season all kinds of stimulants were in requisition to insure a rapid growth, but, from this time, all safe means of retarding vegetation should be resorted to, in order that the season's growth may be ripened to match as our means can afford. These general rules require more use than mere details.

Cleistocactus.—Now, when many will begin to cut down their [illegible] and are [illegible] against [illegible]

[illegible] formerly we used to cut our plants to mere stumps, and now some cut them by far too long, for the sake of making large specimens next year; and with care this may be effected: but the safest way for beginners is to cut the lower-side shoots of this season's growth to 3 or 4 eyes, and if the plants are tall, to cut in the centre about to 1 or 2 eyes. Three years old plants make the finest specimens for ordinary use, providing the roots are healthy. Very old plants of Pelargoniums, that are to be preserved, had better be planted in the open ground, and they will furnish good cuttings in September, which may be kept in stove-pots through the winter, and they will come in excellent succession next summer.

Greenhouse.—Many of the greenhouse plants might be improved by being turned out into the open ground now for six weeks or two months; others might be plunged, with their pots, an inch or two below the surface, when many of their roots turn up to the surface, and thus occupy the whole of the ball instead of being crowded at the bottom of the pot, as is usually the case.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.
Out-door Department.

The work in the flower-garden at the present time is in a great measure routine. Attend to the regulating of all plants and beds, and keep everything as clean and neat as possible. Ply the broom, scythe, hoe, rake, and roller diligently, and at all times. Remove dead flowers and keep a sharp eye to insects and mildew, which is making its appearance on the Roses since the rain.

Reserve Garden.—Some of the biennials will now be fit to thin out a little, and the young plants may, if required, be pricked out in nursery beds for transplanting. Hoe the ground among the plants frequently, not only to destroy weeds, but also to promote the growth of the plants.—*W. P. A.*

[The reader will please to correct the following error in the last Calendar:—Reserve Garden, last line—for "earthings" read "cuttings."]

III.—FLORISTS' FLOWERS.

Carnations.—The green fly, which congregates on the buds, and the minute black insect which, beneath the calyx, eats away the coloured parts, both in Carnations and Picotees, are more numerous and mischievous than usual. The attacks of the former are more easily prevented (being an open foe), whilst the insidious depredations of the other can with difficulty be repressed. We have found dusting the calyx with Scotch snuff, previous to its opening, the best preventive (amongst many) which we have tried. Continue to tie the buds as they advance; waxed thread, wound round the top part about thrice, twisting the ends together with the finger and thumb, will be found the most safe, easy, and expeditious method. An old florist in the north used to get some Windsor Beans, and, cut them transversely, in sections of about the eighth of an inch; when the inside was removed, the skin formed a small hoop or ring; he would fit these lightly on the buds, according to their size: the exposure to the air caused them to shrink, thus fitting the calyx closely, and certainly this was a very neat as well as effectual means of attaining the end proposed. We have yet a novel and simple plan in operation, to prevent the bursting of the calyx, the successful adaptation of which to our own stock will induce us to communicate it shortly for the benefit of our readers. Continue to put down layers; pegs of fern or wood are made use of; we give the preference, however, to those made of lead. Shade the expanding flowers from sun and rain; and amid the multifarious manipulations required just now of the Carnation grower, the best means of raising good seed must not be forgotten, and manual impregnation by all means should be resorted to. *Picotees.*—Continue to plant out rooted pipings. Look well to pods of seed, extract the decayed petals, and slit the calyx down to prevent the extension of wet, which will inevitably cause decay and the loss of the seed. *Dahlias.*—Must be regularly tied up to their stakes, as they are now making vigorous growth; occasional waterings with liquid manure will be of service. *Tulips.*—As we presume they are all safely stored, an occasional glance, to see that all is going on right, is all that is now requisite.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—From now to the end of October is the season most favourable to the growth of Pines: and it is necessary to make the most of it, by paying due attention to the wants of the plants in their various stages. The more strength and compactness we can get into the plants, the greater will be the probability of fine fruit; and to obtain the greatest degree of strength, it is requisite that the plants have plenty of room, with as much air as the weather will permit; and that they be kept in a brisk bottom heat of from 85° to 90°. Too much water at the roots should be carefully avoided, as there is always a greater number of fibres made when the soil is moderately dry, particularly if it be put in the pot in a rough or lumpy state. Plants with plenty of healthy fibre, and broad, strong, but short leaves, cannot fail to produce fine fruit, other circumstances being favourable. Continue to syringe in the afternoon, and if you have no other means of keeping the atmosphere of your houses and pits moist, the tan and paths may be sprinkled once or twice a day.

Vineries.—Let the Vines now ripening their crop have air early in the morning, and increase it as the day advances, shut up early with a dry atmosphere. If the weather should become damp make slight fires. This, by causing the fumes of the sulphur on the pipes or flues to ascend, will assist in the destruction of the red spider. Keep the houses from which the crops have been gathered in the neatest order. The Vines in these houses will require the light to be open night and day. Young Vines of this year's planting should be encouraged to make all the wood possible. Allow all the laterals to grow on these; as it give early, and with proper after management, permanent strength and vigour to the plants.

Peach-houses.—should wet weather occur, make slight fires to dry the atmosphere of the houses where fruit is now ripening. This with plenty of air will help to give flavour to the fruit. If red spider make its appearance, dress the pipes or flues with sulphur and quick lime, and make slight fires to render the application more effectual.

Figs.—Leave a little air on all night, and give a great deal during the day. Let the plants be well supplied with water, and syringe daily except where fruit is nearly ripe.

Strawberries.—Where the crop is gathered from the British Queen, and other kinds suitable for forcing (which in most places is now the case), the strongest runners may be carefully put into small pots, with what roots they have made, the pots having been previously plunged at a proper distance from the parent plant, to prevent the runners being shaded by its foliage. It will be necessary to lay small stones on the runners that have not made roots, to keep them in contact with the soil in the pots till they have time to establish themselves. Should the weather prove dry, watering will be beneficial.

Melons.—Pay a retract attention to stopping and cutting out decaying leaves. Do not let plants swelling their fruit suffer for want of water, but withhold it by degrees as the fruit approaches maturity.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Budding.—The fine mild showery weather we now have presents a favourable opportunity for budding the stocks of stone fruit-trees, and for inserting buds of esteemed kinds upon the branches of established trees; the sorts of which are not approved of. Propagation by budding, though generally confined to stone fruits, may also be resorted to with advantage with scarce varieties of Apples and Pears. Any statements respecting the mode of operation would be futile, after the plain and lucid directions given in the current year's *Chronicle*. I recollect a striking instance of success that resulted from

budding the Peach on established trees of the Apricot; the shoots from the buds growing freely, and producing plentifully, when the general stock of Peach-trees could not be kept in a healthy state, though great pains were bestowed upon them by a very clever gardener. This fact would seem to indicate that it would be worth while to try Apricot stocks for Peaches to a greater extent than is generally done.

Tomatoes.—Keep shoots fastened to the wall or fence; thin out the shoots and leaves, and pinch out the points before the clusters of blossoms, where early fruit is desirable. Without the assistance of a wall they will not do with good success north of London, unless in favourable situations—though I always regret planting them near, as they use such gross feeders. For their culture, Capsicums, &c., and the forwarding of early crops, dwarf walls with sloping bottle-boards are in every garden. It is very fashionable to speak of a gardener as an itinerant philosopher; who crops perhaps rather closely, as an itinerant philosopher; who crops perhaps rather closely, as an itinerant philosopher; who crops perhaps rather closely, as an itinerant philosopher; who crops perhaps rather closely, his fruit from borders, though nine cases in ten it is the result not of choice, but of necessity, aware as he is that the somewhat inferior condition of his fruit trees will not be such an unpardonable evil as being bothered with a constantly supply of the best vegetables. *Peas.*—A last sowing may now be made of some of the early sorts. A sowing of Dwarfs might be made towards the end of the month, where the situation was very favourable, and means of protection could be resorted to. *Asparagus.*—The present weather offers a good opportunity for sprinkling the beds with salt, and supplying them with any rich manure you can spare. *Potatoes.*—Those who are partial to young tiny Potatoes may now plant some tubers saved from the earliest crops. If previously greened in the sun they will grow more vigorously. The rows may either be covered with litter on the approach of frost, or they may be dug up, and the produce kept in dry sand. *Cabbage.*—Prepare for sowing for the main crop next month. In cold situations, they cannot be sown one week too soon; in warm favourable places, it will be as well to defer for eight days. *Routing.*—Keep planting winter-stuff every favourable opportunity.—*R. F.*

FLOWER CULTIVATION.

Old Woods.—See preceding Calendars for what is required to be done in this department.

Coppice.—Go through these frequently, in order to see what is wanting; what you do not observe at one time you may at another.

Young Plantations.—About this time young oaks will be making their second growth; therefore young plantations should be frequently gone over, for high winds sometimes do considerable injury to luxuriant young shoots, and especially to the leaders. Should the latter happen to get broken, they may, in a great measure, be rectified in the same season, and a new leader obtained, if properly attended to.

Miscellaneous work.—Keeping the borders clean, by frequent weeding and hoeing, and attending to pruning and training young plants, is nearly all that is requisite at this season in private nurseries. But remember, the knife should be used now on the young shoots; only the daggers and shears should be employed to pinch off the ends of too luxuriant side shoots.—*W. B*

WILDGOOSE GARDENS.

In consequence of the late fine weather, everything is now growing rapidly, and the hoe, which should never be idle, ought to be more than usually active in keeping down weeds and stirring up the ground between rows of growing crops. The flower borders should also be attended to. Tie up any plants that have been broken down by the late heavy showers, and let Verbenas, which are now making vigorous growth, be pegged down until the space allotted for each plant is covered, after which they may be allowed to grow at random. Particularly attend to the tying of Dahlias, which are very apt to get broken by sudden storms. Remove all crops that have ceased to be useful, as they only exhaust the soil and encourage snails and slugs; and let the ground be prepared for winter Greens, which should now be planted, as soon as possible. While the weather is favourable, Celery, if not already done, should also now be planted in beds, which is the best plan for the cottager, as when planted in this way it occupies less ground. If it is intended to make new plantations of Strawberries, select now some of the strongest runners for that purpose; by planting out early they become well established before winter, and often produce a good crop of fruit the following season. In cottage gardens a row is frequently planted along the sides of the walks, so as to encroach as little as possible on the space required for vegetables, and in such situations, where the exposure is open they often ripen abundant crops of fine fruit. The soil most suitable for Strawberries is a strong rich loam, but they will succeed well in almost any soil that has been properly manured, and is in good condition.—*J. M. H.*

State of the Weather near London for the week ending July 13, 1844, as observed at the Horticultural Garden, Chiswick.

July	Mean Temperature of the Air.			Mean Temperature of the Soil.			Wind.	Rain.
	Max.	Min.	Mean.	Max.	Min.	Mean.

The highest temperature during the above period observed on the 31st, 1825—thermo. 89°; and the lowest on the 27th, 1816, and 26th, 1829—thermo. 40°.

Notices to Correspondents.

The Reprint of Mr. PAXTON'S COTTAGE AND CABINET is now ready, price 4*d.* each Copy. An Index has been added to this present Edition. Parties wishing to have copies for distribution among their tenantry can have them at the rate of 2*s.* for 6*s.*

Bees.—*Valkalla.*—We really cannot do anything in this matter. All we can say respecting Mr. Bettigrew's proposals is that we have ourselves subscribed to his scheme, because we know him to be a most respectable man, whose honesty is unsurpassed for excellence.

Carnations.—*W.*—There are several causes which will produce the effect you mention. The fretchloe, the diseased state of the layer at the joint of covenants from the parent plant, also late planting, especially after such dry weather as we have lately experienced, or should the buds have been infested with Aphis, which have inadvertently been crushed on the pot instead of being destroyed. In all of these highly injurious, and cause the weaker specimens quickly to die. I would recommend watering with an infusion of half a peck of sheep manure in six gallons of water, or with Potter's liquid manure.

Colours.—*Mark.*—Why is it, that all colours appear to a man are different by candlelight from daylight, whilst in those of nature hardly any difference is perceptible? Is this and is it the utmost trouble to obtain such beautiful greens, yellows from white, purples and pinks also are so regular, and go with trees and flowers. [What any one answer this question?—*We cannot.*]

Composts.—*Never employ manure* certainly never for these. It may do very well for Hollies, Laurels, and such evergreens, but is fatal to Cypresses, Yews, Junipers, and the whole Coniferous race.

Dahlias.—*Nemo.*—We know of no better mode of awarding these than pegging them down. It is not necessary to pinch off the flower buds in order to keep up a later bloom, the Dahlias in general flower well until they are cut off by frost.

Heating.—*G. C.*—Sand is better than sawdust for covering a tank, because the latter will breed fungi. We should have no fear of your having heat enough; the great fear is that the soil will get dry. You must provide ample means of watering the soil as well as steaming the air. If you grow Melons in your pit, cover the tank with neither sand nor sawdust, but with good maiden loam.

Insects.—*A Lady.*—Red Spider is not to be destroyed by water; it can only be kept under by such means. A sulphur fumigation is the only effectual remedy.—*S. S. H.*—The Peach-leaf is infested with Aphides. The tree should be syringed with Tobacco-water, and the shoots which most abound with the Plant-lice may be cut off and burnt. The Froth-flies on the Lavender are the larvæ of a Tettigonia, described and figured in the 2d vol., p. 599, of this Journal. *R.*—*A. R. C.*—We shall be happy to comply with your wishes, if you will furnish us with the necessary materials. *R.*—*B. Child.*—No. 1 is Curculio scrophulariæ; No. 2, Curculio nubila; 3, Altica testacea. *R.*—*W. M. C.*—Not finding any winged specimens in the quill, we cannot be certain regarding your Aphides, but believe them to be the Cinara laricis of Curtis's Guide. Be so good as to send us living specimens of the Caterpillars, for we cannot tell you what it is that destroys the foliage of your Larches. *R.*—*R. N. C.*—The leaves of the Geraniums are affected by damp, and not by insects. The roots of the Pansies are suffering from the attacks of young Snake Millipedes, which are exceedingly difficult to destroy: unslaked lime, or lime-water, will be the best applications, and you will find other remedies and the history of the Juli, in the *Gard Chron.*, vol. i. p. 196. *R.*—*A. B. C.*—Your insect is Pentatoma rufipes, which generally feeds upon caterpillars, &c. *R.*—*B. Child.*—The moth is Zygæna filipendulæ; and the other insect is the larva of a bug, called Pentatoma. *R.*

Manures.—*W. R.*—We really do not see what we can do to satisfy you; we will, however, consider against another week.

Names of Plants.—*Zephyrus.*—Pellæa grisea.—*An Enquirer.*—Plantago major. Destroy it by constantly cutting through the crown of the root with a sharp spade.—*Subscriber.*—Geranium sanguineum.—*T. U. M.*—Oncidium triquetrum.—*H. Doubleday.*—Stachys recta. We never received your former parcel.—*R. Durant.*—Your leaves are attacked by a parasitical fungus. We really can suggest no better remedy than stripping the tree and burning every one of the leaves.—*W. Bentall.*—Apparently Carex pallescens.—*H. H.*—The Poke-root may be the Phytolacca decandra, called the Virginian Poke.

Pelargoniums.—*Simplex.*—These have become diseased no doubt on account of having been kept too dry. Being potted in leaf-mould, chopped turf, and having a good drainage, they require a very great deal of water, especially during such a season as this.—*Fanny.*—The truss, cut from the Sylph, which you have sent, bearing a perfectly white flower, among the others, is not an uncommon occurrence; at the same time, nothing is known, beyond a white flower having been one of the parents of the particular variety that bears it. How a single flower in a truss, or an entire truss, should come white, when the rest of the flowers are pink, is a matter involved in obscurity. Having had one branch with a complete truss of white flowers, we recommend you, by all means, to strike it, as the plant produced from this cutting will in all probability produce white flowers—and a white Sylph, with the size and substance of that favourite variety, will be a very desirable acquisition.*

Planting.—*A Card.*—All that has been published concerning Dr. Thackeray's mode of pruning is to be found in our columns, where it has been often mentioned and commented upon.

Rats.—*L. Y. Z.* is desirous of knowing the meaning of the term "slamm" in a communication by "G. C." on the 25th May last. Moreover, a piece of calico is to be used rather larger than the trap—Is this to be placed under the trap, and the corners tucked in? or are other pieces of calico to be put all around the trap?

Rhododendrons.—*Mrs. Gall.*—These may be grown in a chalky soil, provided pits are formed for them, and filled with leaf-mould. The holes should be tolerably wide, but need not be more than eighteen inches deep. Mould composed of loam and leaves will do. Whatever leaves are used must be thoroughly decomposed, and if they can be mixed with one half peat so much the better.‡

Strawberries.—*G.*—The best varieties for a market gardener, both with regard to quantity and quality, are Keen's Seedling and Myatt's British Queen. The former is an excellent forcer.‡—*J. W. Yellow.*—Your soil being strong, if once unusually dry, no surface watering would have been sufficient to insure the perfection of your Strawberry crop, but under such circumstances, irrigation produces the desired effect. Like yours, plants are apt to die in intervals between imperfect surface-waterings. Your sand is the "sharp silver sand," mixing so that used for propagating. It is valuable, and if you have it in abundance, a mixture of it would improve your stiff Strawberry soil.—*A Subscriber.*—If your beds of Keen's Seedling exhibit signs of decay, your best plan will be to make a fresh plantation. You may obtain good crops from those that do not yet exhibit such symptoms, if you keep them clear of runners, giving them a top dressing of light manure and fresh loam in winter. The Elton Strawberry is a fine sort, rather acid if not perfectly well-ripened. We never before heard to complained of as being tender, and suspect you have not obtained the true kind.‡

Swiss Briar Hedge.—*R. R.*—This may be obtained by sowing the hips of the Rosa rubiginosa in the autumn as soon as ripe; or, which is better, in the month of March, having kept them in the meantime mixed with sand. But it is far more convenient to buy sweet-briar stocks, (young plants) from the nurserymen, and to plant them, about early in the month of November. Let them grow as they like for the first year, and cut them down to the ground the second; they will then spring up and require no more care than the occasional trimming with the pruning-knife or shears, so as to keep the hedge in shape. When it gets naked at the bottom it must be again cut down.

Vines.—*A Subscriber.*—The Vine leaf you sent bears strong marks of the Red Spider, together with a little scorching. As the shoots are ripe, the best thing you can do is to cut them down to the bottom if you be desirous of having fine fruit next season; as soon as their vegetation is at rest for the present season.—Another Subscriber, who has sent a leaf from a Vine that has not been fired, but has blistered, and has brought with it large excrescences, in an intermediate stage from the small white pimples under side of the leaf to the production of blisters, caused by the dried-up state of the intermediate portions of cuticle.

Vines.—*S. S.*—We presume you intend to train within the same kind of net as is usually employed for that purpose; but which is prepared at a somewhat coarser mesh, and is [illegible] strachan; and water to be added. [illegible] plants and has for [illegible] tisement would produce them.—*J. H.*—No. 10 of last year, and 6 for the present, may be had. No. 6 is out of print—send your address with 13 pence stamps. [illegible] Your [illegible] planted upside down, attempting to recover its position, and nearly succeeding. It is a curious fact, already known, that Hyacinths will produce coloured flowers, even although grown in the dark. The phenomenon, which is extremely remarkable, has never been explained; nor can we explain it. Possibly the external matter is formed the year before; but, if so, where; and in what form is it hidden in the bulb?—*C. J.*—Spearmint in paper cases, we believe, would go by the overland mail, without any other care than that of drying them properly. If yours are too bulky, they will go very well by sea, if packed loosely in coarse canvas bags, and kept in a cabin, or some other dry place. Seeds will go very well in boxes of tin, or to send them long, the best, is to kill them. Ripe cuttings taken off in November, with their ends stuck into a Potato, and well covered with an India-rubber or other waterproof envelope, sometimes reach India safely by the overland mail; but they more frequently fail. Such plants are despatched by the Post-office, or if too heavy, by the Indian agents.—*A Lady.*—No plant is more simple to manage than Euphorbia splendens. It only wants a stove heat and a moist atmosphere. It is very different from some kinds of Cape bulbs. See some remarks on the subject, at p. 293 for 1843; where the treatment of Brunsvigia is described.—*N. O. P.*—We never heard of taking Cats [illegible] are unable to answer your question as to [illegible] You had better apply to dyers. In using Whitney's Composition, the linen should be boiled slackly at first, and then, after the first application, stretched tight before it is nailed.—*W. D.*—There is no such thing as male and female Geranium or Fuchsia blossoms. Each flower contains the two sexes.—*A Constant Subscriber.*—The Portulacaria [illegible] under the name of Cissus [illegible] named *Ercetum*, the foliage of which is smooth and of a deep green; the one named *Gilvum* [illegible] the same colour, but more [illegible] and the other named *Subscriber.*—The Sweet Briar does not make a good stock on which to bud the Damask and Perpetual Roses, but the Noisette may be budded with success on the Sweet Briar.—*W. W.*—Your two Vines in pots, infested by red spider, will not be injured by being placed out of doors, and the red spider will be much more easily destroyed in the open air than [illegible] For the method of laying down a Pine-pit, we would refer you to Loading Article, p. 379, vol. 1843.—*J. H. Watson*—We find the [illegible] described by Devonensis repeated at p. 391 of this year;—*Rev. Lewis Evans.*—Your Pines are mildewed by the dry weather; there is no doubt; but we do not see how your Vines can have suffered from over-luxuriant growth.—Depend on it, if you have a large and abundant crop of Grapes, with you have wood, be must be the better gardener of the two. There is no remedy for your Nectarines now; dry weather and drought [illegible] Red Spider has taken off your leaves. All you can now do is to syringe plentifully and treat to manure. On no account shade; if you do, you will have no flavour in your fruit. You will learn how to procure Green Peas by unwilling to [illegible] vol. for 1843, p. 174.

SEEDLING FLOWERS.

Fuchsias.—*Z. Z.*—The best variety among your seedlings is Hebe, being bright and pleasing in colour; but none of these flowers can be regarded as improvements upon those already out.—*J. Y.*—The peculiar character in the form of your flowers; its great length must render it very showy on the plant.—*C.* is very pretty; but the colour is not new. *J* and *E* are not new.—*Rhum.*—Of your seedlings, John Bull is ugly in form, with the corolla so short that it is scarcely seen. The sepals of the *Président* are coarse, and there are many in the same way. Gallia, with light tube and sepals, and a rose-purple corolla is new, as you say, but does not surpass others in the same way.—*W. Tenterden.*—We find no improvements in your present batch of seedlings; neither in size, colour, nor texture, are they equal to the numerous varieties already in cultivation. Something new is required, as there is so much monotony in the sorts cultivated, that would decidedly advantage the [illegible] make exhibitions of this popular flower attractive.

Gloxinias.—*A Reader.*—Your seedlings are good, and very inferior to some.

Pelargoniums.—*H. D.*—Your seedling is [illegible] rich crimson purple, the white coming given it a lively appearance; it is tolerably good both in form and substance.—*J. Y.*—Your flower was being well pasted, the petals [illegible] fallen, and were partially dried by [illegible] to form an opinion of its qualities.

Peruvians.—*C. E.*—Several fine Peruvians have been exhibited this season, of the kind characterized by your seedlings. Some of your varieties are very [illegible] Mrs. Lilac; was damaged, but appears to be good in colour [illegible] s, white, with dark very purple [illegible] a good variety. [illegible] sion. The other varieties [illegible] You can cultivate [illegible] regarding a guarantee. A few of our blooms, and plants in pots, covered with flowers, were exhibited at the Horticultural Society's Garden on Saturday last, that is the description given of the flower in this paper.

Phlox Drummondi.—*T. S.*—There is nothing uncommon in your seedling; the colour is bright and pleasing, but the form of the [illegible] is indifferent.

Pictures.—*R. C.*—Your specimens can only be regarded as border varieties; the petals are too small, and the colour not sufficiently outlined to the edge of the petals. Do not [illegible] the heat.—*Rondi.*—Your seedling [illegible] but the guard petals [illegible] they are small, rather crumpled, and not even on the edge. In other respects, as the flower, as the white is pure, the petals [illegible] and the [illegible] edging of a beautiful colour. Your next [illegible] has very fine guard petals, and the centre ones are quite [illegible] uneven on the edge; good pod, petals [illegible] slightly serrated, and the [illegible] the number of petals. No. 3 [illegible] a good sized flower, with petals of a good form; but several of them are [illegible] pled and broken. [illegible] edge, rather inclining to [illegible]

Verbena.—*A Subscriber, from the Commencement of Your seedling being packed up without anything [illegible] about it, was to say a little about [illegible] it was impossible to tell [illegible] colours, and it would not [illegible] Your seedling is a very good variety, [illegible] of a delicate blush-ring, changing to white, but [illegible] a little colour at the [illegible]

As usual, many communications have been received [illegible]

SEED-WHEAT.—Any one desirous of purchasing Seed for next year is invited to inspect the two varieties of Wheat, RUBERETTE, IMPETUEUX, and MORETON'S NEW STRAW WHITE, 180 acres of which are now growing on WHENNELD FARM, THORNBURY, GLOUCESTERSHIRE.

The present is the only season of the year when the value of any variety of Wheat as Seed can be ascertained by instantaneous test, if the examination of a mere sample of the grain which can be seen at any time, be merely satisfactory as to its quality in the eye of the baker or the miller, it is entirely so as to the predominance or debility of growth of the variety to which it belongs. Those points, which are of the highest importance in the eye of the Farmer, can be ascertained only by an examination of the growing plant, when in full ear.

JOHN MORTON, Whitfield, Thornbury.

The Agricultural Gazette.

SATURDAY, JULY 20, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Tuesday, July 23, Yeomanry and Cattle Show, Maryland Meeting.
Wednesday, July 24, Meeting of the Agricultural Society of England, at Southampton.
Thursday, July 25, } at Southampton.
Friday, July 26, }
Saturday, July 27, Agricultural Prize Soc. of Ireland.
Monday, July 29, Agricultural Society of England.
Tuesday, July 30, Agricultural Prize Soc. of Ireland.
Wednesday, July 31, Bingley Cattle Show.
Aug. 1, Huddersfield.
Aug. 2, Great Yeomanry Meeting, at Framlingham.
Aug. 3, Peterboro'. July 30, Isle of Thanet.
Aug. 5, Great Yeomanry Meeting, at Bayleigh.
Aug. 6, Thame. Aug. 5, Collumpton.
Aug. 7, Cirencester.
Aug. 8, Gloucester.

FIFTY-NINE THOUSAND POUNDS' WORTH OF GUANO (we quote from a statement by Mr. Milne at the late meeting of the Scottish Agricultural Chemistry Association) were last year imported into Liverpool alone. But guano is imported direct from its sources into many other ports of the United Kingdom beside this; indeed, advertisers are daily announcing the actual or expected arrival of cargoes direct from African or Peruvian islands at second and even third-rate seaport towns, so that the sum here named is perhaps not an eighth of what has been spent in the purchase of this manure during the present season; and, from the better knowledge which prevails of its fertilising properties, as well as from the enormous supplies which will by that time have arrived in England, we may suppose, that if this year's value of guano sold be reckoned by tens, that which will be bought by farmers next year will be reckoned by hundreds.

Now we ask, Is not the expenditure of some hundreds of thousands of pounds on a substance so often, because so easily, adulterated as this—an expenditure too by parties generally so incapable of detecting the fraud—is not this a subject of serious agricultural importance? It is absolutely necessary that farmers should combine to insure themselves against a source of such serious loss, to the action of which they are so liable; for we can tell them that if the articles which have lately appeared on this subject in the *Agricultural Gazette* have failed to awaken them to their true interest, they have, by no means been so uninfluential on the parties whose roguery they exposed. These gentlemen see that it is necessary now to have a semblance of authority for the value of their trash, to insure its sale; and, as illustrative of this, Mr. Gyde, of Painswick, whose name is well known to our readers, lately gave us the following account of an attempt made upon him:—

"The object of the party in sending me the sample of guano so shamefully adulterated, was to ascertain if I would become an agent for its sale; if so, I was to receive a handsome commission, &c. My answer was to be left at a Post office, and every precaution was taken to prevent the locality being detected, in case the proposition did not meet with a favourable reception. The so-called guano consisted of a mixture of red marl and old mortar crushed together to the extent of 95 per cent.; the remaining 5 per cent. consisted of vegetable matter (probably partially decomposed sawdust), and genuine guano. This mixture had been moistened with putrid urine, and re-dried. It certainly had the appearance of a fair sample of guano when casually looked at, and would no doubt deceive any person unaccustomed to the genuine article. When moistened with caustic potash, and heated, it only gave traces of ammonia compared with the effect produced on natural guano; and after drying and heating to a red heat, 45 per cent. of inorganic matter was left, which did not contain 1 per cent of phosphates. I think the answer I sent them will prevent their offering it in this neighbourhood. The largest amount of adulteration of guano I have met with has been 15 per cent., excepting the above instance."

This case, in point of impudence, can be compared only with the notorious instance published by Mr. Solly, in which a manure containing only 3 per cent. of what it professed to be, was considered to be good enough for agricultural purposes.

Well, there can be no doubt after this, and the many other instances we have at various times published, that there is a necessity for vigilant carefulness in the purchase of guano. It is most desirable that Farmers' Clubs, and especially all those in inland districts, should adopt the means suggested by Mr. Hyett of Painswick in an early number of this Paper, viz., each of them nominate some scientific man as their agricultural chemist, and secure his services, at a certain rate of charge to the analysis, *before purchase*, of all concentrated manures, natural or artificial. We allude to inland Farmers' Clubs particularly, in reference to the purchase of guano, for farmers near sea-ports can buy at the ship's side; and though, through error, or impurities, it may have been imported, yet impurities to any considerable amount are, in ninety-nine cases out of the hundred, to be attributed to the roguery of secondary manure dealers, after it has been brought on shore. The general and hearty adoption by Farmers' Clubs of means, such as this, would go far to deter dishonest people from attempting this deceit. But the subject must be taken up immediately, if it be intended to exert any influence; for guano is daily arriving in this country, and unless sufficient influence be exerted to the contrary, as soon as it is cheapest it will be bought up from the importers, in order to be adulterated and diluted ready for next spring.

Only one Society, that we know of, has heartily adopted the plan to which we allude, and that—a Society, indeed, formed for the very purpose of securing for the farmer the services of the chemist—is the Agricultural Chemistry Association of Scotland. The Report, in another column, of the half-yearly meeting of this body, is well worthy of perusal. It will be seen what success has attended the efforts which have been put forth in Scotland to bring the farmer and chemist together. The circumstance mentioned at that meeting by Mr. Milne, that all the instances of fraud in the manure-trade, which we have published, have occurred south of the Border, is sufficiently convincing of the influence exerted by the existence of a ready and certain means of detection.

It is not guano alone which these district agricultural chemists would have to analyse—they would find cases of adulteration in many other manures. Mr. Gyde informs us that he lately analysed, for a farmer near Chepstow, in Monmouthshire, a specimen of bone-dust, in which he found 20 per cent. of sand, and 12 per cent. of water, so that, for all agricultural purposes, one third of it was useless. One would think, from the constant occurrence of these instances of fraud by manure-dealers, that, though familiar with it from childhood, farmers were not yet convinced of the expediency of the old rule—

"Taste and try, before you buy."

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

THE word in the above title, which is meant to express the character of the following contributions to the *Gazette*, is intended at the same time to signify that dependence of the farmer's practice on the nature of the soil he cultivates, and therefore on the geological character of his vicinity, which it is my object to illustrate.

South Gloucestershire, perhaps, more than any other district in the kingdom, possesses a very variable geological character; the character of its agriculture is also various, and an attentive survey of it will convince any one, as it did me, that these stand to one another in the relation of cause and effect.

In order that my remarks on its farming may be useful, I must first describe its general appearance and climate.

The district to which the following remarks refer, is that portion of Gloucestershire which extends on the east and south to the boundaries of the county, on the west to the river Severn, and on the north to a line drawn from near the village of Frampton-on-Severn to the town of Stroud. The whole of it is included in No. 35 of the Maps of the Ordnance Survey. Its greatest length, from N.N.E. to S.S.W., is about 26 miles; its greatest width, from N.N.W. to S.S.E., is about 16 miles. Looking at it with regard to the elevation of its surface above the level of the sea, it may be divided into two portions—the one on the elevated table-land of the Cotswold range, and the other constituting the extensive tract in the vale of the Severn between Gloucester and Bristol. The average elevation of the one is from 500 to 600 feet above the average level of the other; and of the 330 square miles which constitute the extent of the whole district, about 80 belong to the hilly portion, the rest to the vale. The two districts are divided by a bold edge or escarpment, stretching between them in a direction N.N.W. and S.S.E. The surface of the table land slopes towards the east, its highest points being always near the edge of this escarpment; and these are, therefore, situations from which a very accurate idea of the general appearance of the whole country may be obtained. In the northern and southern parts of the district the table-land is furrowed out by valleys of considerable extent, which are independent of one another; each is complete in itself, possessing a series of lateral branches, into which, again, a second series of smaller valleys run; their sides thus present a number of recesses and promontories, to which, chiefly, the beauty of their scenery is due. In the same way, the front of which the Cotswold range consists—the bolder rock—is made up of a series of nearly horizontal beds of various kinds—limestone, clay, and sand—the valleys which cut through this series of beds have upon their sides the characters of each, and another source of variety in their scenery is introduced.

As all of them occur close to one another, the whole being within a space of ten miles, the high land generally presents outliers in the form of long arms, which extend as so many headlands into the vale. From the extremities of these arms the most beautiful and extensive views of the vale may be obtained, and instead of proceeding to state at the outset, as to the character of the surface of only the second portion of our district, it may be well to attain one of these heights and obtain thence a view of its general appearance.

Stinchcombe-hill, which stands further out into the midst of the vale than any of the neighbouring hills, being at the extremity of the tongue of the arms just mentioned, will best suit our purpose.

If we climb this hill early on the morning of a summer's day, we shall probably find the whole of the vale covered by a thin stratum of white cloud, which hides from us, as a sea, the whole of the country it rests upon. The high lands on the far side of the Severn appear as a distant coast, ourselves being on the top of one of the boldest headlands which here stretch far into the midst of the strait.

As the heat of the day increases, this cloud gradually disappears, and discloses to us the beauties of the land it had covered. Looking to the north, the east, and the south, we see stretched out before us the vale of Gloucester and Bristol; on looking eastward, behind and on either side of us, we find it bounded by the escarpment of the table-land already described; and as we gradually direct our gaze from north to south over the western horizon, the Malvern hills in the far distance—May Hill—the Forest of Dean—the distant Welsh hills—the open sea in the Bristol Channel—and the Mendip hills beyond Bristol, successively pass under review. These boundaries present every variety of outline and appearance—they form a fit frame for the beautiful picture which they surround. The scenery of the vale itself also varies in its character. Northward its surface is comparatively level; to the south it is irregularly broken up into hill and valley. In the northern part of the vale the city and cathedral of Gloucester may be seen at a distance of 15 miles, and here and there over the whole of it, villages with their church spires make their appearance. We can see very little but pasture land, indeed, with such immense quantity of timber as everywhere covers the vale, arable land could not be cultivated.

Isolated portions, however, in the midst of the thickly wooded country below us—the surrounding the foot of the hill—another near Frampton on Severn—a third between these—and others, are bare, and cultivated by the arable farmer. This hinders any monotony to which the scene would otherwise be liable. The northern part of the vale consists chiefly of clay, but there here spots occur where a deposit of gravel has taken place over the clay; a difference in the subsoil thus producing an entire change in the appearance of the surface.

The southern part of the vale is, as I said, broken up into hill and vale. A ridge, or southern escarpment, about 150 or 200 feet high, commencing at Bristol, and running northwards 15 miles, when it runs out by Tortworth and Wickwar, and again southwards to Sodbury, incloses a basin-shaped tract of country of considerable extent; and, besides this, many detached hills occur here and there, as in the neighbourhood of Thornbury and Berkeley, adding to the irregularity and beauty of the scenery.

The climate of this district does not vary much in point of temperature, being of such limited extent. It is probably, however, always from 2° to 4° colder on the table land than in the vale, and this, where, as in this case, it is united with a much greater degree of exposure, will make a great difference in climate.

At Bristol, the following is the monthly average temperature, in degrees of Fahrenheit's thermometer:—

January.	February.	March.	April.	May.	June.
37.3	40.8	41.3	47.1	55.8	61.9
July.	August.	Sept.	Oct.	Nov.	Dec.
63.	61.5	57.3	51.7	43	40.6

The average number of wet days in the year at Bristol, is 166, which are divided out among the months as follows:—

January.	February.	March.	April.	May.	June.
15	12	15	10	9	13
July.	August.	Sept.	Oct.	Nov.	Dec.
14	13	20	16	20	17

At Cheltenham, the following are the results of meteorological observations, which have been carried on for seven consecutive years, during the first eight months of the year; and for five years, ending 1837, during the remaining four months. The average temperature for each month is as follows:—

January.	February.	March.	April.	May.	June.
37.6	40.4	41.5	46	53.9	59
July.	August.	Sept.	Oct.	Nov.	Dec.
61.1	59.7	55.5	50.4	43.9	41.6

The average quantity of rain which falls in the year at Cheltenham is, according to these observations, 31.81 inches, which is divided amongst the months as follows:—

January.	February.	March.	April.	May.	June.
2.17	3.55	2.1	1.26	1.6	3 21
July.	August.	Sept.	Oct.	Nov.	Dec.
3 58	2.79	3.15	2.96	3.36	2.12

These observations give the average temperature of the year at Bristol, in the south of our district, 50°; and at Cheltenham, beyond the north of it, 49°.

The temperature of Chalford springs, occurring in the valley of that name, three miles east of Stroud, which are the largest springs in the county, does not vary throughout the year, and may be taken as the average annual temperature of the place, it is 49° 8.

The temperature of a considerable spring, near Hillday, was, in the month of August, 50°. This, too, may probably with accuracy be taken as the temperature of

the place. Neither of these, however, occur on the table land, the annual temperature of which is, probably, above 3° degrees less than either.—*M. S.*

ON LIQUID MANURE.—No. III.

(*Concluded from p. 467.*)

In pursuing the above subject, for the purpose of ascertaining the cheapest and most economical method of converting the ammonia generated in urine by putrefaction into a fixed salt, we next come to *Sulphuric Acid.* This acid, from the large quantity which is used in our arts and manufactures, is now produced at a much cheaper rate than formerly. It offers the most certain, if not quite the cheapest mode of fixing the ammonia contained in putrid urine by at once entering into chemical combination with it. When sulphate of iron, sulphate of lime, or any of the soluble salts are used for this purpose, a double decomposition occurs: the two constituents of the substance used are separated, and enter into new combinations with the ammonia; but before this change can take place, the two substances which are intended to react on each other—*i. e.*, before the acid of the one can combine with the alkali (ammonia) of the other, both must be in solution; and when the substance used to fix the ammonia is sparingly soluble as is the case with gypsum, much care and time is necessary effectually to accomplish this object. But when the acid itself is used, no such inconvenience takes place; the acid at once combines with the ammonia, and forms a sulphate of ammonia, while carbonic acid escapes with effervescence. In using sulphuric acid in liquid manure, there are several advantages obtained over that of gypsum, or sulphate of iron, since in the first place no deposit takes place in the tank, which requires it to be occasionally emptied; and if a slight excess of acid be added, no injurious action is exerted by it on the plants, should it in this state be added to the soil; indeed, a slight excess of acid in the tank would be more beneficial than otherwise, since urine contains no inconsiderable portion of phosphate of lime and magnesia; and an excess of acid would convert this into a superphosphate, which is more soluble, and, we have every reason to believe, far more efficacious than phosphate of lime or bone-earth; for by the use of a small quantity of bones dissolved in sulphuric acid, by which a soluble superphosphate of lime is formed, we are enabled to produce as large a crop of Turnips as by the use of many times the weight of bones without the acid.* When sulphuric acid is used in liquid manure, it may be added in small quantities as long as any effervescence occurs, stirring the liquid after each addition, and waiting until the effervescence has subsided before any fresh addition of acid be made; and it is advisable that this should be done at intervals of ten days or a fortnight where convenient. In purchasing sulphuric acid, care should be taken to ascertain that it is of full strength, namely, of 1·85 specific gravity; and, as its strength is in direct proportion to its specific gravity, this is a good criterion by which the purchaser can protect himself against imposition. The following is a mode by which an inexperienced person may ascertain if it be undiluted:—Fill an imperial pint with water, and place it in the scales, having first balanced, or ascertained the weight of the empty cup; the water should weigh 20 ounces; remove the cup, and pour away the water, then fill it with the acid the strength of which it is required to ascertain, and again weigh it; if it weighs about 17 ounces more than the pint of water, the acid is of ordinary commercial strength, but if much less, it has been in all probability diluted.

Common Salt has been strongly recommended to fix the ammonia in urine, since it was thought to possess the double advantage of not only forming a muriate of ammonia, by the acid contained in the salt combining with the ammonia in the urine, but because the carbonate of soda which would also have been found would act as a beneficial manure, supplying plants with an alkali: and, if this theory had been correct, salt would certainly have possessed great claims on the farmer's attention; but unfortunately the decomposition which goes on when concentrated solutions of common salt and carbonate of ammonia are mixed together, takes place on too limited an extent in diluted solutions, as we meet with it in urine, to be of any service to the farmer. When two concentrated solutions of salt and carbonate of ammonia are mixed, a quantity of carbonate of soda and muriate of ammonia are formed; the carbonate of soda being comparatively insoluble in a solution of muriate of ammonia, it is deposited in the vessel, and may be separated by a filter. But if this mixture be largely diluted with water, and the carbonate of soda redissolved, the elements again arrange themselves in their original form, namely, carbonate of ammonia and salt. Strange as this may appear to those unacquainted with chemistry, it is nevertheless the case that when strong solutions of the above salts are mixed, a decomposition takes place, which does not occur, or at least very partially, in less concentrated solutions; and as putrid urine is a weak solution of ammonia, salt undergoes little or no decomposition when mixed with it. Hence the ammonia does not become fixed, neither is carbonate of soda formed. *Muriatic acid*, spirits of salts, or hydrochloric acid, may be substituted for sulphuric acid to fix the ammonia in urine. It is, like sulphuric acid, extensively used in the manufactures of this country, and may now be purchased of the manufacturers at three farthings per pound, when taken in quantities. Like sulphuric acid it combines at once with the ammonia, forming muriate of ammonia; it leaves no deposit in the tank, and may be used in the same way as the sulphuric. In conclusion I have inserted the following table, which shows the ingredients used to fix ammonia, the quantity of each required to form 1 cwt. of sulphate or muriate of ammonia, the cost, and the quantity of ammonia fixed.

Substance used.	Weight in lbs required.	Cost.	Ammonia fixed in lbs.	Salt of ammonia produced. lbs.
		s. d.		
Unburnt Gypsum	146	3 6	30	112 of sulphate
Burnt ditto. . .	118	—	30	112 ,,
Sulphate of Iron .	224	3 8	30	112 ,,
Sulphuric acid .	84	7 0	30	112 ,,
Muriatic acid .	80	5 0	35	612 of muriate of ammonia

N.B.—The cost is calculated from the market price of each article.—*Alfred Gyde, Painswick*

ON ROTATIONS OF CROPS.

SEEING that you invite your readers to communicate the results of their experience or observation, particularly in matters which intimately concern the horticultural and agricultural communities, I beg to offer you a slight sketch of the different rotations of cropping practised on the model farm at Glasnevin, near Dublin, which is under the Commissioners of National Education for Ireland, and superintended by that intelligent agriculturist, Mr. T. Skilling. A great deal is said now a days about the rotation of crops, and very justly so; yet upon the whole how few are there that put a good system of rotation into practice. If this communication be the means of imparting the smallest amount of information on so interesting a subject, the writer has his reward.

This farm consists of about 50½ statute acres, and is composed partly of a deep loam and partly of a light soil; it is worked by 12 young men, with the assistance of two horses, each boy giving six hours work per day—the remaining part of their time is devoted to agricultural study, of such subjects as chemistry, botany, animal and vegetable physiology, &c. The farm-house, gardens, barns, and cattle-sheds, &c., occupy between three and four acres; the remaining 49 are divided into two rotations of four and five crops respectively. The four-crop rotation consists of 19 acres laid down in fields of 4 acres 3 rods each. The five crop rotation consists of 30 acres, divided into fields of six acres each. The reason why it is laid down in two rotations is to show the pupils the practical working of both systems; were it not for that, the whole 49 acres would be laid down under the five-crop rotation. The number of stock usually kept on the produce of the farm is 20 cows, 2 horses, and from 15 to 20 pigs; the cows are fed during the winter six months on Turnips, Mangold Wurzel, Potatoes, Hay, Straw, &c. The produce of the first two—Turnips and Mangold Wurzel—averages from 35 to 40 tons per acre, say 38 tons; each cow is allowed, with Hay and Straw, the growth of one rod of Mangold Wurzel, Turnips, &c. Suppose an acre produce 38 tons, 1 rod will yield 9 tons 10 cwt., which being reduced to pounds, will amount to 21 280; this again divided by 190 days, which is rather more than six months, will leave 112 lbs. for each cow per day, which is a large allowance for ordinary sized cows.

The amount of crops raised on the four-crop rotation is as follows:—In field No. 1 (see table No. 2).—Mangold Wurzel, Turnips, &c., 4 acres 3 roods. No. 2.—Oats, 4 acres 3 roods. No. 3.—Same quantity under artificial Grasses, such as Italian Rye Grass, perennial Rye do., and Clover. No. 4.—Do. of Wheat.

The crops on five-crop rotation are as follows:—No. 1.—Potatoes, Turnips, Mangold Wurzel, &c., 6 acres. No. 2.—Oats, 6 acres. No. 3.—Grass pasture, 6 acres, a portion of which is reserved for Hay. No. 4.—Consists of Italian Rye Grass, perennial do., and Clover, which is cut three times during the summer and autumn months for the support of the stock; a great portion of the last crop is made into Hay, for the support of the cattle during the winter months. No. 5 contains the same quantity of land, which is under Wheat or Barley. The total amount of crops raised on the farm is as follows:—Oats, 10 acres 3 roods, Wheat, do. do.; Potatoes, do. do.: cutting Grass, do. do.; Grass pasture, 6 acres; grand total, 49 acres. The produce of 20½ acres of Corn is sold, the remaining 28½ is consumed on the farm. Each cow is calculated to give 8 quarts of milk on an average daily, which, sold in the market at 2*d.* per quart is, for one cow, 1*s.* 4*d.* per day, per year, 24*l.* 6*s.* 8*d.*; or, for 20 cows for one year, 486*l.* 13*s.* 4*d.* The cows are kept from two to three years, and then beginning to go off milk, are fattened and sold, their places being always supplied by others in full milk.

I ought here to mention that the cows are, strictly speaking, housed summer and winter, except two hours each day during the summer months they are allowed to exercise on a portion of the Grass pasture. By this method the greatest possible quantity of manure is collected, which is the great support of the large and luxuriant crops, of Wheat, Oats, Turnips, Grass, &c., The tables Nos. 1, 4, and 5, are sent merely with the view of showing other rotations which might be advantageously used, particularly Nos. 4 and 5, on a larger scale and different soils. A good deal more could be said on this subject, but perhaps enough for the present.—*B. M., formerly a Pupil in the above Establishment.*

No. I.—*The Three-Crop Shift* is the best adapted for small farms near a market town, because you can keep more cattle on the same quantity of land than on any other rotation, because there are two green crops and one grain crop. It is as follows:—

	1st year.	2d year.	3d year.
1st yr.	Potatoes and Turnips	Wheat or Barley, sown down with Grass seeds	Cutting Grass
2d yr.	Wheat, Barley, &c. with Grass seeds	Cutting Grass	Potatoes, Turnips, &c.
3d yr.	Cutting Grass	Potatoes and Turnips	Wheat and Barley with Grass seeds
4th yr.	Same as first		

No. II.—*The Four-Crop Shift* is best suited to strong, heavy soil that is able to bear cultivation; it is very beneficial to the farmer in localities where it can be followed; it is termed alternate husbandry:—

1st year: Potatoes and Turnips. 2nd year: Wheat and Grasses. 3rd year: Cutting Grass. 4th year: Oats. 5th year: Same as first.

No. III.—*Fifth Rotation, or Five-Crop Shift*, is best suited to light soils; it is chiefly followed on the light soils of Scotland; it is a good rotation for raising food for cattle; it has three green and two grain crops; they are as follows:—

1st year: Potatoes and Turnips. 2nd year: Wheat, Barley, and Grass. 3rd year: Cutting Grass. 4th year: Grass pasture. 5th year: Oats. 6th year: same as first.

No. IV.—*The Six-Crop Grass Shift*; its crops are only fit for light, hill, or peat lands. It is well adapted for rearing young cattle or sheep.

1st year: Potatoes or Turnips. 2nd year: Barley or Oats, with Grass seeds. 3rd year: Cutting Grass. 4th year: Grass (second year). 5th year: Grass (third year). 6th year: Oats. 7th year: same as first.

No. V.—*The Six-Crop Bean Shift.* This rotation answers well on heavy clay soils; it is as follows:—

1st year. Potatoes and Turnips. 2nd year: Wheat and Grass seeds. 3d year: Cutting Grass. 4th year: Oats. 5th year: Beans. 6th year: Wheat. 7th year: same as first.

ON THE APPLICATION OF MANURES.

A PLANT has been defined as a compound organic body, deriving nourishment from the soil in which it grows.

This definition appears to have been generally admitted, and has been almost universally acted upon, by depositing in the ground such matters as are thought to furnish this nourishment to the roots, while a power, stimulated by light and heat, elaborating the atmospheric air and the sap, has been supposed to reside in the leaves. Some few—Tull and his disciples—have disputed the utility of so depositing these matters; they proposed, by hoeing the ground, and such like operations on the surface of the soil, to promote its disintegration, and the admission into it of the atmospheric air, in order to supply the roots with gases; and these seem, in a great measure, to be the views of Liebig. Lord Kames and others, again, have contended, and, by some apparently conclusive experiments, have attempted to prove that water is the sole nutriment of plants; but—which seems to have escaped the observations of all—may it not be supposed that the matters thus deposited in the soil, instead of supplying plants with nourishment through their roots, may really so supply them through their leaves and the greener parts of their stems?

When we look at "one of the giants of the vegetable world," stretching far, wide, and deep his vast roots into the bowels of the earth, we must feel convinced that his first and most obvious purpose is so to fix himself as to enable him to brave the storm; his second, to obtain from the soil the means of growth and of prolonging his existence. What does he seek? He plunges his roots deep in the soil; does he do this only to keep hold of it? Does he not do it also to seek food? And what food? The decaying animal and vegetable matters lie near the surface; the action of the atmospheric air, and the heat of the solar rays, do not penetrate the regions he traverses. It is water which he searches after; and this, say some, is the sole food of plants, elaborated in their leaves—this, they say, is all that it is necessary to supply them with. To the experiments made to prove this hypothesis, in which distilled water has been alone supplied to plants set in ground glass, cotton, sand, &c., it has been objected, with much truth, that "these experiments are always performed in or very near houses, where the air is not so pure as in the open fields, and consequently where they have an opportunity of receiving as much nourishment from the air as may compensate for the want of what they would have derived from the earth, if planted on a rich soil. Here, then, is an admission by those who would impugn the evidence of these experiments, and by the advocates for enriching the soil to feed the roots, that plants may be nourished from the air filled with effluvia from the habitations of man. Can it be denied that they may be equally fed by effluvia in the open fields, from the decaying animal and vegetable matters in the soil? It may be said that ammonia is absorbed by the water in which the roots are placed, but it is more probable it is sucked in by the leaves; the contrary opinion has tended more to check the progress of the wide-row system than all the prejudices of ignorance. "We know," says Liebig, "that the functions of the leaves, and other green parts of plants, is to absorb carbonic acid, and, with the aid of light and moisture, to appropriate its carbon."

* In adding sulphuric acid and water to bone-dust (phosphate of lime), the sulphuric acid combines with part of the lime, forming sulphate of lime, while the phosphoric acid which is left attaches itself to the remaining portion of undecomposed bone, and forms with it a superphosphate of lime, or bone-earth, with excess of phosphoric acid which is soluble in the mixture. Hence, we have a mixture of sulphate of lime and superphosphate of lime. May not the increase of crop from the use of such a mixture be partly attributable to the sulphate of lime? and would not a portion of gypsum, used with bones increase the crop, by placing within the reach of the roots of the Turnip a substance which cannot fail to form part of its nourishing food? since it is known to contain lime (25 tons of Turnips containing about 140 lbs. of lime) as well as alkali, both of which the sulphate of lime would yield to the crop.

Sir H. Davy and others have justly objected to naked fallows, that they facilitate the escape of nutritious effluvia from the soil, when there are no plants to absorb them; and that, if nitrous salts are produced in bad weather from exposure of soils containing vegetable and animal remains, it is probable at the expense of ammonia; and this is not denied by the advocates of summer-tillage. In hoeing between the rows of fallow crops, the objects contemplated appear to be the loosening of the soil. Liebig says—"By loosening the soil which surrounds young plants, we favour the access of air and the formation of carbonic acid"—the destruction of weeds, and "the ploughing up of the plants, with the intent of benefiting them. The benefits aimed at by loosening the soil are the admission of the atmospheric air into the soil, there to operate on animal and vegetable matters in the earth for supplying the roots with food. In the words of Liebig, "The carbonic acid, which protects the undecayed humus from further change, is absorbed and taken away by the fine fibres of the roots, and by the roots themselves; this is replaced by the atmospheric air, by which process the decay is renewed, and a fresh portion of carbonic acid formed." But in the widest rows, and with the horse-hoe and plough, the soil is not stirred to a depth exceeding six inches, while the finer fibres of the roots of most plants, to which this deep hoeing is applied, reach certainly very far beyond this depth; and it is the extremities of these fibres that are the mouths of the roots. I admit that some of the roots shoot laterally some of their branches, probably still to seek moisture; but broad-cast Wheat, and Wheat sown in rows rarely exceeding nine inches asunder, are rolled, harrowed, and hoed with the same object, where merely the surface can be bruised and torn up, while the Wheat seed is sown from four to six inches deep, the roots extending to a much greater depth, and the finer fibres probably a foot or two below the surface, to a depth, indeed, to which we cannot suppose, even under the most favourable circumstances—those of fresh-sown ground—the influence of the atmospheric air can penetrate for the purposes of vegetation, for few seeds will germinate much below six inches. The advantages of destroying weeds cannot be disputed, but the benefit of moulding up plants is very questionable: it was never practised or recommended by Mr. Coke (Lord Leicester), of Norfolk, for White crops: to Turnips it is not considered beneficial; to Mangold Wurzel injurious; and I can myself vouch that, for Potatoes (to which roots it is generally considered most applicable), it is useless, except in a final hoeing, to allow a freer passage of air along the rows.—*T. M. C., Stramore Police, Stranraer, Ireland.*

(To be continued.)

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Farm of Grunnesoon.—East Lothian has been long noted for the comparative excellence of its tillage-farming; in no district, perhaps, is rural labour more skilfully executed. As I have already stated, I am by no means desirous of representing the system of farming pursued in this county as the most judicious in every respect that could be devised; much less am I anxious of holding it up as a perfect model of rural economy, for the imitation and guidance of all readers of the *Gazette*. Whether the East Lothian system of farming is superior or inferior to that pursued in some of the most improved districts in England, I am unable to say. It may be proper to observe that my remarks upon the agriculture of this county apply solely to its average character, and not to what is practised only by a few more advanced or enterprising than their neighbours. There are, undoubtedly, many examples of unskilful and slovenly management to be met with in some localities.

The following, among other circumstances, have obviously contributed, to a considerable extent, in bringing about an improved mode of tillage in this county, viz.: the extensive practice of thorough-draining, the invention and employment of efficient implements and machines for executing and economising rural labour, the nature of the soil itself, and the manner of hiring and general management of farm servants; to these, of course, is to be added the security for the outlay of capital which is afforded by the lease. The advantages arising to the tillage farmers of this county from the complete drainage of their land, and the use of effective implements, are too numerous and apparent to require any elucidation here. Even after being thoroughly drained, the strong stubborn nature of the greater part of the soil renders it, in unfavourable seasons, peculiarly difficult, expensive, and precarious to work to any degree of perfection; and this disagreeable quality of the soil has undoubtedly contributed very much towards the general adoption of improved cultivation, as it compels the anxious and industrious farmer to resort to every expedient, and to try every mode of management which practical judgment—often the result of dear-bought experience—could devise. Nor must the admirable manner of hiring and managing farm servants, long successfully pursued in this county, be overlooked in enumerating some of the leading circumstances which have conduced to its improved cultivation. By far the greater part of the regular farm-labour is performed by married servants, provincially termed hinds. They occupy comfortable houses provided for them by the farmer, and which are always situated near the farm-steading. They are hired by the year, and paid partly in money, and partly in the produce of the farm, as shall be more particularly detailed in a subsequent article. The advantages arising to both master and servant from this system, are many and obvious. The hind, from his permanency of employment, naturally acquires an interest in the prosperity of the farm, has usually an anxiety to perform with care his own assigned duties, and from being closely confined to one sort of work, has evidently a better chance of becoming thoroughly a master of it.

Premising these general remarks, I shall now proceed to describe the manner of performing the principal tillage operations, as they are at present practised on the generality of farms in this county, beginning with the most important and indispensable of them all, viz.:—

Ploughing.—It may be necessary to explain some of the technical expressions connected with this subject, employed in this and other parts of Scotland. Land once formed into ridges, is subsequently ploughed by either of the following methods, viz., 1. The ridges may be split out in such a way that the space formerly occupied by the crown of the old ridge becomes the furrow of the new. This operation is technically called *crown-and-furrow* ploughing. 2. Two ridges may be ploughed together, by which means the form of the old ridges, and the situation of the intermediate furrows, are preserved unaltered. This mode of ploughing is termed *casting*. 3. The ridges may be *gathered*, which is effected by beginning at the *crown* or centre of the ridge, and ploughing all the furrow-slices towards it. By this means an increased elevation or curvature is given to the ridge. 4. The last operation may be reversed by commencing at the furrows without ploughing into them, and concluding at the crown, which then becomes an *open* furrow. This process is called *clearing*, the ridges being, when this method of ploughing is adopted, divided or cloven into halves. Each of these modes of ploughing shall be afterwards more minutely described.

Feering, or *feiring*, is a Scotch term, referring to the opening of the first furrow-slices in ploughing a piece of ground, or the process of marking off or *striking* the furrows which regulate the after ploughing of land into ridges. Where the ploughing of a ridge or other piece of ground terminates, is called an *open furrow*; thus, when the crown-and-furrow mode of ploughing is pursued, every furrow is an open one; but in the case of the ridges being cast only every fourth, one becomes an *open* furrow, the others are termed *close* furrows. The last furrow-slice in ploughing a ridge or other piece of land is generally named the *hinting* furrow. When ridges are ploughed, by turning the horses at the headlands to the right about, as is sometimes done in the case of gathering, they are said to be *hupped in*; and when ploughed by turning from right to left, as in cleaving, the ridges are said to be *rounded out*. The most of these technical expressions will, doubtless, appear rather strange to southern readers, and may probably sound somewhat harshly in their ears, but they are well understood in all parts of this country. Their use, however improper in a Paper like the *Gazette*, is almost unavoidable in describing the different methods of performing the important operation to which they refer. I shall endeavour, however, to employ only those local terms which cannot be dispensed with, without occasioning some prolixity of detail. One of the ploughmen, generally the steadiest and most skilful, on every farm is appointed to the rank of *foreman*, a station next in point of trust to that of the steward or *grieve*. The usual duties of the foreman are to feer or mark off the land into ridges, both for himself and for the other ploughmen, to conduct the process of ploughing and other tillage operations, and to regulate the time for stopping from and recommencing work. He is also generally required to stack and sow corn, for which he commonly receives two bushels of Wheat yearly, in addition to the ordinary wages of a ploughman.—*T. Sullivan.*

AGRICULTURAL IMPROVEMENTS.

HAVING in my three former letters disposed of the details of my farming operations, I will now proceed to consider,

First, The imperative necessity of agricultural improvements in a national point of view, and how those improvements can be most readily effected.

Secondly, The defects in the present system of farm valuations, and evils resulting therefrom to landlord, tenant, and country.

Thirdly, The relation of landlord and tenant to each other in a pecuniary point of view; their identity of interest, and the importance of long leases, with Covenants.

Fourthly, Suggestions for rendering the Royal Agricultural Society a standard and model of agricultural improvement in every essential point.

Lastly, Popular but prevalent errors as regards agriculture, with a few general remarks.

The existence of a superfluous capital, with a superabundant unemployed population, is a dangerous anomaly, threatening, in its continuance, ultimate destruction to our nation. Luxury for the wealthy few, and poverty for the willing, but unemployed many, must produce discontent, anarchy, and ruin. It is an alarming fact, that much of our income is derived from the capital we lend to foreign countries; whilst, in our own, we dole out grudgingly, in rates and in charities, a tithe of what ought to be the just and well-earned wage of the industrious but unemployed labourer.

Ask the majority of your independent friends whence they derive their income? The widow will tell you, "My money is making a road, cutting a canal, or building a town in America." The orphan will say, "Mine is supporting a civil war in Spain or South America, or growing corn in Russia for the London market." The capitalist will report his strong-box full of bonds—Chilian, Colombian, Peruvian, Mexican, French, Spanish, Dutch, Portuguese, Russian, Austrian, Prussian, and Neapolitan (some of which, by-the-by, pay neither interest nor principal); but neither the widow, the orphan, or the capitalist will tell you their money is profitably and delightfully engaged in growing food for themselves and their families—in providing employment and profit for their fellow-countrymen, of every grade, from the labourer to the merchant. No! Agriculture has had as yet no charms for the capitalist or speculator. The one lends his money to strengthen foreign competition in agriculture, commerce, and manufactures; the other sows uselessly and prejudicially more seed than the total annual amount of our Wheat importation—the extra quantity sown actually diminishing the produce to a similar extent; yet all this takes place whilst we are complaining of superabundant capital and population, as if an industrious population could be too great. My opinion is, the more numerous we are the more prosperous we shall be, for we live by one another. The denser the population the greater our power and our trade, provided we keep our capital at home and at work amongst ourselves.

To ship off our labourers and our money is nothing less than suicide. It is giving away, economically and politically, the sinews of our strength; and I call upon every man who has the welfare of his country at heart to put a stop to it. How is this to be done? I answer, Easily; and point to my operations at Tiptree Hall Farm, as a solution of the difficulty. If every capitalist expends, as I have done, 40*l.* sterling money in improving each acre of poor and indifferent land, the sum total required would be many hundred millions. I need hardly point to the magical effect of this expenditure on our trade, commerce, and manufactures. Every individual in this country would feel it. It is too grand and delightful a prospect to hope to realise. There is too large a mass of miscalculation, ignorance, prejudice, pride, and long custom to be removed. Facts and results will scarcely do it; but reason and truth must prevail at last: and I look forward with hope that the patriotic, the intelligent, and the wealthy will exercise their influence, by example and precept, to procure so desirable a result. Agriculture is our sheet-anchor; to that we must look for employment and for profits: it is a vast field for enterprise: it is our vital strength as a nation; and one pride of country alone should stimulate us to be independent of foreigners for the supply of our daily bread—the staff of our lives.

In considering how these improvements can be most readily effected, it is quite clear that individuals generally have seldom the means, the ability, or the inclination to carry out a perfect system of agricultural improvement: it must be done by companies of associated capitalists, the same as our railways and other great undertakings. I will venture to assert from experience, that there is not, in agricultural undertakings, one tithe of the difficulty or uncertainty that attended railway operations. Rival companies will be beneficial to the public by the protection of competition. General rules, however, on fundamental principles, must be obtained by sanction of Act of Parliament; and I apprehend an examination of competent authorities would lead to a table of laws adapted to the security and profit of the shareholders, the benefit of the landowner, and the welfare of the tenant. Mortgagees might transfer their mortgages to the company, with full authority to carry out necessary improvements, on condition of receiving from the company all benefits over and above five per cent. interest for the company's capital. Should the landowner desire a sale, the company would have the opportunity of purchasing outright by public competition; or the landlord might have the power of redeeming his property, on paying the company principal and interest up to a period of sufficient notice. In all cases where there is not an absolute sale, landlords should have the power of redeeming their property or transferring it to another company, under equitable arrangements to both parties. The variations in rents and prices of corn would be no greater, on an average, than the fluctuations in railway or other shares.

As to the fear of companies engrossing land, the same objection cannot apply to them as to charities. Shareholders invest for profit, and rivalry will necessarily prevent oppression. What tenant would not rather trust to fair competition under a company than to individual favour, cupidity, or caprice, to say nothing of the uncertainty of individual life? Landlords would also benefit. Frequently now (I know several cases) a landlord, without agricultural knowledge, is prevailed upon, by a designing or an incompetent tenant, who shows an annual statement of heavy losses, to reduce his rent, till he receives but two per cent. for his money. I proceed to consider—*The propriety of valuing improvements; the defects in the present system of valuation, and its evil results to the landlord, the tenant, and the nation.*

At present a bad farmer is almost sure to get a new lease (for who is anxious to take it after him?) whilst a thorough good one is almost as certain to be turned out, or have his rent raised—the landlord being generally ready to avail himself of those improvements which a wise farmer is compelled to make for a profitable return. These improvements are *bonâ fide* his property, and ought to be legally as much so as the coat on his back; and it is a scandal and disgrace that they are not valued to the incoming tenant.

Let us see, in fact, how it acts on the landlord. I shall prove clearly he is a loser by it ultimately.

The outgoing tenant is obliged in self-defence to starve the land and injure his crops the last four years of his lease, whilst it takes the incoming tenant another four years to repair the damage done by his predecessor; so that between the two there is during eight years less

labour and capital employed, less food grown, less profit made, and an increase in the poor's rate, without any corresponding benefit to the landlord. In nine cases out of ten an improving tenant resists being charged a large interest, in the shape of increased rent, on his own capital. He makes way for a miscalculating bad farmer, who ruins the land, ruins himself, and ultimately the landlord is obliged to put up with a small rent—not, however, till all parties have been put to considerable regret, inconvenience, and expense, arising from exchange of residence, to the nothing of expensive sales, valuations, and leases, whose acquaintance with the peculiarities of a new farm, and the breaking up of many friendly and relative ties, formed during a local residence.—*J. J. Mechi, Leadenhall-street.*

(*To be continued.*)

ON MINERAL AND INORGANIC MANURES.

No. XXII.

By PROFESSOR CHARLES SPRENGEL.

(*Continued from page 480.*)

Sand.—Sand, as everybody knows, is an aggregation of loose small grains. Generally it is believed that the grains consist merely of quartz or silica, but by closer examination it is found that many grains of feldspar, mica, iron ore, silicates of potash, soda and lime, oxide of iron, &c., are amongst the main mass. If, therefore, sand is brought on fields, we must not believe that it merely improves them mechanically; on the contrary, we may assume that it furnishes them with sources of vegetable nutriment. Because, although the mineral substances of which it is composed (such as they are) are not soluble in water, still they are decomposed by the humic acid, and gradually changed into food of plants. For marshy, or very humic soils, even the quartz is a manure, as it supplies them with silica, in which they are mostly deficient. As the value of sand, as a manuring substance, consists in the quantity of those of its mineral component parts which are fit for becoming the food of plants, obviously that is to be chosen which is richest in lime, soda, potash, and magnesia silicates; this, however, can be only ascertained by chemical analysis, which has hitherto been entirely neglected. Sand, moreover, used as manure, ought to be very fine, as it will then present to the humic and carbonic acids, which have to decompose its silicates, a greater surface for contact; a clayey soil, nevertheless, which has to be loosened and improved by sand, requires that of coarse grains. Although sand, generally speaking, is only used for the improvement of clayey or very humic soils, it may be also useful for chalky soils; as this sort of soil is always deficient in that quantity of silica which is required for the food of plants, and especially for that of the cerealia.

On stiff clayey soils, which require an improved texture, a sand is to be used which contains many grains of lime, as these will loosen the soil even better than grains of quartz. On the sea-coast that sort of sand, therefore, which is thrown out by the waves, is used with much success for the improving of clayey fields, as it always contains fragments of shells, rich in carbonate of lime. It is generally first used as litter, and then carried (mixed with excrements) to the clayey fields, which, if the process is often repeated, will not only be improved physically, in the driest manner, but also become very fertile. In the manuring of clayey soils with sand, the toughness of the former will always make a thorough mixture with the sand very difficult, at least by manual labour; it will, therefore, best to leave it to Nature. The coarse-grained sand may be spread over a field to the thickness of a quarter to half an inch, at the time when it is used as pasture, as in this case it will not only be trodden in by the cattle, but will be also conveyed downwards into the small crevices which are to be found in a dried-up clayey soil*—an operation which will be also assisted by the rain-water. The first subsequent ploughing is done very shallow, and the first crop should be Oats. After the lapse of a few years, or when the field is used as a pasture, sand is again spread to the above thickness, which, in fact, is repeated until the clayey soil is changed into a loamy one. The same process is resorted to if sand is used for the improving of moors, peaty and marshy soils, be it used as a pasture, meadow, or as arable land; but here the thickness of the sand strata may be 1 to 1½ inches. It will improve the moor, if it be only by compressing it by its weight, and it will bring the organic matters to speedier decomposition.

I may state here that the proportionally bad growth of crops on soils very rich in humus depends (besides some other reasons) on their roots not finding enough oxygen in the soil; which substance, as it penetrates gradually into the ground, is seized by the carbon of the humus, and then cannot be used as food of the roots; for which, nevertheless, it, is absolutely indispensable. The following experiment will corroborate my assertion:—I selected a light loamy soil, containing 3 per cent. humus, and a considerable amount of protoxide of iron. Part of this field had borne for three years Clover, and other parts alternately Oats and Vetches; both parts were dug up together on the 28th of April to a depth of 6 inches, and without being manured at all. I planted them both at once with Oats. On that part where the Vetches had ripened the year before, the Oats grew up in three days; whilst on that which bore the Red Clover, the Oats did not come out of the ground till after 6 days. One might have supposed that the Clover-Oats should have come up to the Vetch-Oats, on account of the better nourishment at its command; but this was not the case. It stood always sickly, and it ripened in part only as the ripening period came on. This phenomenon may be thus explained:—The soil which, on the previous year, had borne Vetches, was so loose that the atmospheric oxygen had constant free access to it; and as it therefore continually supplied new matter for the oxidation of the humus as for that of the protoxide of iron, the Oats found at once as much as they required for speedy germination, and subsequent luxuriant growth. The soil, on the other hand, which had been under Clover during three years, did not afford during this period any nutriment to the oxygen; and when it was at length dug up, the humus and the protoxide of iron (perhaps also the rotting Clover-stalks), took up so much of oxygen—of which they had been so long deprived—that little remained for the roots of the Oats; and thus occasionally crops are prevented from succeeding on soils very rich in humus, to that extent which other circumstances might warrant us to expect. Humic soils will, it is true, absorb more oxygen than any other soil; but they will not keep it in a free state, as it is immediately used for the formation of carbonic and humic acids. Thence it may be deduced, that a soil which contains much undecomposed humus will be much improved if a part of the humus is destroyed, or if any large quantity of a substance be conveyed thereon, which will tend to diminish the amount of it. The former is done by burning and converting it into ashes; the latter, by covering it with a thick layer of sand, common earth, or loam. It is long since both these plans have been adopted with the best effect; and although it is beneficial in many other respects, it is chiefly so in this that the less quantity of humus will then not deprive the roots of the plants of oxygen. If a very moory meadow, or one which has been previously drained, be supplied with much sand, say to the height of 4 to 5 inches, the sour Grasses and Mosses will be suppressed; and if then Oats with Clover and Grasses are sown, they will find in the old rotting Grass such a source of rich nourishment, that they will grow very luxuriantly, at least for some time. More on this subject is found in my work on Cultivation.

If there are fields very rich in humus, where Rye is grown, sand a quarter or half-an-inch thick may also be strewed to great advantage in winter over the frozen soil; it will then also prevent the freezing of the crops during the spring. It has been stated before that sand may be used in stables as litter, and the dung thus obtained may be used as a manure on moors.

As sand is always used in large quantities, its effects are lasting, unless it sinks in marshy soil so deep as to be altogether beyond the reach of the roots; in this case it will even act no longer physically; so that the spreading of it must be repeated. Clayey and chalky soils, on the other hand, will be constantly improved by large quantities of sand, as the water cannot then carry off any of it.

* It will also be ultimately buried by the worms.

HISTORY AND CULTIVATION OF WHEAT.

In what country Wheat is indigenous is not easily ascertained; all opinions must now rest merely upon conjecture. We read of its cultivation in the earliest records of history.

The migration of seeds and plants has been assisted by the sea, the wind, and graminivorous birds, and quadrupeds, as well as by the hand of man, so that it is impossible in all countries to distinguish the indigenous from the foreign.

Wheat is now found growing in a great variety of climates—from the north of Africa to the south of Sweden—but it is more particularly in the temperate zones that it is cultivated with any success. In Norway, Sweden, and Denmark, its cultivation and consumption is very limited; if we turn our course southward we find it cultivated in abundance, and forming the principal constituent of human food; if, again, we proceed still further south, till we arrive within the tropics, we find that the indigenous plants, as Rice, Millet, Maize, &c., are more extensively cultivated as an article of food and commerce, Wheat being cultivated only occasionally. Its character appears also to accommodate itself to circumstances. Sir Joseph Banks, in one of his many papers addressed to the Horticultural Society, mentions in 1805 having received some seeds from a lady, among which was a packet labelled "Hill Wheat," the grains of which were not larger than the grains of our common Grasses, but when magnified exactly resembled Wheat. These grains he carefully sowed in his garden, and was much surprised on obtaining as the produce a good crop of spring Wheat, the grains being of the ordinary size; he made inquiries as to the history of the seed, which proved fruitless, all that could be learnt was, that they had been received from India.

It cannot be doubted that Wheat followed in the train of the conquerors of foreign lands, as we find it related in the history of Cortez, inhuman as he was, that when subduing Mexico to the Spanish yoke, he wrote thus to the King of Spain:—"I beseech your Majesty to give orders that no vessel sails from Spain without a certain quantity of grain and plants; we shall not proceed here as we have done in the islands, where we have neglected cultivation and destroyed the inhabitants; a sad experience ought to teach us otherwise." We may naturally draw from this, its introduction into our own island by the Romans, who, on their gaining a footing in Britain (54 A.C.) found the British tribes living exactly as the Indians do now, upon animals caught in hunting, and on roots and plants indigenous to the island, tillage being unknown, except along the coasts. Whether the order of Cortez was obeyed or not, we have no authentic account; but the foundation of the Wheat harvests in Mexico is said to be the produce of a few grains, which a negro slave of Cortez accidentally found in 1530 amongst some Rice; these the careful negro preserved and cultivated, while, had they fallen into careless hands, they would have been lost to the country. The introduction of Wheat into Peru was the produce of a few grains carried to Lima by the wife of Diego de Chaves; her name, and the regard she took in distributing the yearly produce of these grains amongst the inhabitants, are gratefully recorded in history. However careful she had been in distributing the blessing to Peru, its general cultivation did not commence till after the introduction of Wheat into Mexico; for in the year 1600, Wheaten bread was considered as articles of luxury, and scarcely known in the important city of Cuzco. And so grateful were the inhabitants of Chile for its introduction into that country, by a Fleming, that the records of the monastery of St. Francis preserve, as a precious relic, the rude earthen vessel in which the grains first reached that country.

In Canada Wheat is cultivated in abundance sufficient for its own population, and for exportation to the mother country, where it is received upon more advantageous terms than Wheat the produce of any part of the Continent of Europe. In the United States Wheat is cultivated, as in the temperate regions of Europe, but from improper cultivation, is of much inferior to the produce of our own island. In the Spanish Provinces of Brazil, Buenos Ayres, and Chili, Wheat is abundantly found; and it is a principal article of cultivation at the Cape of Good Hope, yielding there a return of one hundred, with a small proportion of bran. Wheat also flourishes in Australia, and is now the object of general cultivation.

The process of making bread is much similar to that used by us at the present day. We have in the east at a very early period, one to find out the people who are the discoverers, to whom we are all so much indebted. The Jews knew the art of making bread 1600 years before the Christian era, as we are informed in Holy Writ, but they were forbidden the use of leavened bread during the Passover; and there can be no doubt but they learnt the art of making bread from the Egyptians.

Pliny informs us that the ancient Gauls and Spaniards were the first to find out the secret in the process of bread-making, leavened bread being used before; and is still is, in some parts of the south-east of Ireland, and other countries. At Paris, about the 17th century, the bakers used yeast instead of leaven, but the faculty of medicine in 1668 declared it injurious to the health; and many years elapsed before the bakers could convince the public that bread raised by yeast was better than that fermented by leaven. Previous to the 16th century, there were no bakers' shops in London, which may seem strange; the inhabitants of Stratford were baked for their week's use, and they sold their bread every day except Sundays and great festivals, which was brought in carts, and they were ordered to stand—three in Cheapside, one in Cornhill, and one in Gracechurch-street.

At the commencement of the last century, Wheaten bread became generally used by the laboring class in England; for we find that in 1795, it was used in the poor-houses in the southern counties. During the 16th and 17th centuries, it was only used by the higher class, and that only on particular occasions, amounting to Eden, in the year 1747, so small was the quantity of Wheaten bread used in Northumberland that, it was, only a rich family that used a cask in the course of a year, and that was used at Christmas. The usual treat for a stranger was a thick Oatcake and Butter. The Author of the "Three Tracts on the Corn Trade," published at the beginning of the reign of George the Third, says, "It is certain that wheat-bread is become much more generally the food of the common people since 1689 than it was before that time; but it is still very far from being the food of the people in general." At that time, he calculates the number of people in England and Wales to be 6,000,000, and 3,750,000 of that number used Wheaten bread.

The estimated average consumption of Wheat in the United Kingdom, at the present time, is 12,000,000 qrs., or 96,000,000 lbs. per annum, or nearly 33,000 quarters each day.

At the present time, Wheaten bread is used more or less in all civilised countries. In Ireland, however, and some parts of Scotland, the working-class live entirely upon Oatmeal and Potatoes, with milk, when it can be procured; and in some districts, as those of Norway and Sweden, in years of scarcity, it is no uncommon occurrence to see trees stripped of their bark to make bread, the bread being made of the inner bark next the wood, first steeped in warm water, to remove its astringent flavour. It is then hung across a rope to dry, and when dry, it is ground with the Corn into meal.—*J. M'Intosh.*

Home Correspondence.

Potatoes.—There is a great failure in this neighbourhood of all sorts of Potatoes except the early ones. One thing I have observed for many years, that wherever Potatoes have been accidentally left in the ground, no matter how severe the winter's frost, such Potatoes always have vegetated early and well; and this, I conclude, is from their not having spent themselves by throwing out shoots, as they would do if taken up and caved, being thoroughly ripe. Hence I prefer those tubers as seed which have not been perfectly ripened, because not being thoroughly ripe, there is the less probability of their vegetating before being planted out.—*T. T. Hawkey.*

Late Horse-hoeing and Digging.—In reading your Leading Article on the horse-hoeing of Turnips, a query occurred to me, viz., "At what period of their growth

would the hoeing cease?" It is evident that a late brse-hoeing when the soil is permeated, as you describe, with the roots of the Turnip, so that "a handful of earth could not be taken up which was not full of these silken-looking fibres," must break into Beetle, Slugs, or Insect nests. Now, the question is, Is this breaking of the roots beneficial or injurious? The late Mr. Cobbett (or by his assistant), contended that it was beneficial, and practised in the principles of Tull (and also the Duke of Bedford) in Corn, &c. up to a very late period of their lives. They said that the composts which had been applied to the manure roots in a trifling and scattered way, were of far greater good derived from exposing the soil to the influence of the atmosphere, and from the greater vigour with which gathered by the plant when the broken roots have pushed up new rootlets. This seems an important point in agriculture as well as horticulture, not yet satisfactorily ascertained by actual experiment. In gardening, except in the case of Peas and Potatoes (and the advantages of confining their roots chiefly to ridges is not very obvious), the practice of digging is not to stir the earth except very superficially, so as merely to keep down weeds between the crops of Cabbages, Lettuces, &c. The experiment might be easily made by setting part of a plot remain under the ordinary culture, and hoeing the remainder (or digging up in the latest period of the plant's growth); and a similar experiment might be tried as to horse-hoeing part of a field of drilled Turnips or Wheat; and I should strongly advise agriculturists and horticulturists, who have the opportunity, to institute these experiments, in order to ascertain what the facts really are.—*S.* The question put by our Correspondent is a very important one: the evident advantage which has attended the practice on our own farm, of horse-hoeing, as long as the leaves of the Turnip plant will permit, would incline us to approve of Cobbett's answer to Mr. Tull, that horse-hoeing sends out a dozen branches from the cottage, and thus any temporary check which the plant may receive is soon swallowed up in the increased vigour of its growth.

Fixation of Ammonia.—In your last Number this year, I forwarded to you a statement of some interesting experiments made by me on the fixation of ammonia by sulphuric acid in liquid manure, and that gentleman has since called upon me for further particulars himself. I had hoped long before this to have said something further on the subject of experimental research in agriculture, but one thing or another has so occupied my time that I have been continually prevented from turning my thoughts to a fresh communication. I hope, however, soon to resume the subject. In the mean time I will be grateful to any of your readers who may have undertaken the little experiment I proposed last year to the farmers of Sussex, that the time is drawing nigh when I hope to have such questions answered satisfactorily filled up. By satisfactorily, I do not mean favourably to any particular result, but fairly and accurately. I have spoken with some persons who have undertaken the experiment, but they tell me they can *see* no difference between the plots supplied with the addition of the gypsum, and those destitute of it. But let me remind them all that Mr. Pusey said he could *see* no difference in the experiment he tried, but yet he obtained a most marked difference by the scales. As yet I have only received the schedule filled up—for Turnips; and in this case the results have been decidedly in favour of the application of the gypsum. Without entering into any of the details, I will just mention what the result has been; though I would say, as I have said before, I put no faith in the results of one or two, or scarcely in a dozen such experiments. The results are estimated from the data, from the proportions actually obtained:—

	Bushels.	tons.	cwt.	lbs.
Unmanured land	360	15	7	16
Unmanured dung	540	20	2	96
Do. (only half the quantity of dung)				
No manure applied	320	16	5	26
Superphosphate dung	960	17	1*	8
Do. (gypsum added after it had fermented)	960	18	8	64

—*J. S. Henslow.*

Additional System.—Two out of the three families, consisting of 22 persons, now living in comfort on only 13 acres of land were pointed to the Eastbourne and Hellingly Union Bazaar, in 1840. They keep books for the inspection of the guests who favour them by inspection; and their books contain the signatures of numerous farmers, clergymen, and members of both Houses of Parliament, confirming the truth of the statement, and the excellence of the crops they witnessed; and amongst the most recent are the signatures of the Earl of Devon and Captain Kennedy, Secretary of the Landlord and Tenant Commission, who kindly took the trouble of coming, on the 15th of June, from London, to examine, in detail, this simple plan, by which, if it were general, more might be saved in Poor-rates in England and Wales only, than the entire amount of the Income Tax from the whole of the United Kingdom.—*A. A. C.*

Guano, Natural and Artificial.—I beg leave to offer the following experiments to your notice.—I selected a Grass field, intended for Hay, and divided it into two equal parts; I top-dressed the one with Potter's artificial guano, and the other with African, at the rate of 3 cwt. per acre, both being mixed with fine sand; the result, after mowing and making into Hay, was fully double in favour of the African material. I procured the one direct from Potter's manufactory, and the other out of a ship direct from Ichaboe to this port. Now, when we take into consideration the price of Potter's guano—12*l.* per ton, and the other 7*l.* 10*s.* or 8*l.*—the difference is so enormous, that I at least shall not be induced in a hurry to use any more of the former. As by experiments only, similar to the above, can we hope to put on their guard against deception and imposition, I think everybody ought, in justice to their neighbours, to give publicity to any trials they may make of new manures or methods, noting carefully the comparative results.—*T. Stanley, Whitehaven.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A WEEKLY BOARD was held at the Society's House in Hanover-square, on Wednesday last, the 17th of July; present—The Right Hon. Earl Spencer, President, in the chair; Duke of Richmond; Earl of Essex; Viscount Hill; Hon. R. H. Clive, M.P.; Hon. G. H. Cavendish, M.P.; R. Archbold, Esq., M.P.; J. Baines, Esq.; T. E. Barker, Esq.; J. R. Barker, Esq.; S. Bennett, Esq.; J. I. Briscoe, Esq.; Sir A. de C. Brooke, Bt.; E. Buller, Esq., M.P.; F. Burke, Esq.; Dr. Calvert; Rev. T. Cator; Col. Challoner; F. C. Cherry, Esq.; E. Divett, Esq., M.P.; T. B. Evans, Esq.; W. Y. Freebody, Esq.; Sir J. S. Forbes, Bt.; W. F. Hobbs, Esq.; J. Kinder, Esq.; W. Miles, Esq., M.P.; E. M. Mundy, Esq.; A. Ogilvie, Esq.; E. W. W. Pendarves, Esq., M.P.; E. S. C. Pole, Esq.; Sir R. Price, Bt.; H. Price, Esq.; P. Pusey, Esq., M.P.; Prof. Sewell; W. Shaw, Esq.; R. B. Sheridan, Esq.; E. Thomas, Esq.; J. Towers, Esq.; and T. Tweed, Esq. The following new members were elected:—

Ingram, H. F. Meynell, Hodness, Rugeley, Staffs.
Platt, Henry, Priestly Farm, Hitwick, Ampthill, Beds.
Atkinson, John, Charlton, Salisbury.
Olivier, Col. H. S., Manor House, Polleme House, Devizes.
Farquharson, Henry James, Langton, Blandford, Dorset.
Biddle, Waring, Long Ham, Wimborne, Dorset.
Rayne, Robert, Flatts Farm, Bishop Auckland, Durham.
Harvey, William Francis, Purbrook Heath, Portsmouth.
Bailey, Edward, Martyrs Worthy, Winchester.
Edwards, Henry, Winchester.
Price, Charles, M.D., Brighton.
Edgell, Richard Wyatt, Milton place, Egham, Surrey.
Baker, Major T. R., Wivley Court, Plymouth.
Cartwright, George, Lyme Regis, Dorset.
Adams, Samuel, Ware, Herts.
Brookes, William, Elmstree, Tetbury, Glouc.
Gawner, Francis, Coombe Wood, Kingston, Surrey.
Kingsford, John, Esher, Surrey.
Page, James, Merton, Surrey.
Coe, Robert, Tilney, Lynn, Norfolk.
Burness, James, M. Corghill, London.
Hony, Rev. W. E., Baverstock Rectory, Salisbury.
Morrice, George, Eling, Southampton.
Withers, Richard, Luzborough Farm, Romsey, Hants.
Ashhurst, John Henry, Waterstock, Oxford.

The names of 22 Candidates for election at the next meeting were then read.

DESTRUCTION OF RATS.—Dr. Ure, F.R.S., communicated, through Mr. Pusey, M.P., the following results of his experiments on the best mode of preparing phosphorus as a poison for rats:—

"In the Journal of the Royal Agricultural Society there was published, several months ago, a prescription for preparing a poison for the above purpose, by an English gentleman resident in Germany. That preparation consisted essentially of phosphorus mixed with flour and sugar. It has been tried by a friend of mine in Derbyshire, who has a most extensive farm, and found to answer the purpose well; but there is a great difficulty in preparing it, from the insolubility, and even immiscibility, of phosphorus in water, attended with no little danger of fire. The process I have found to succeed perfectly is as follows:—Melt hogs'-lard in a bottle plunged in water heated to about 150 deg. Fah.; introduce into it half-an-ounce of phosphorus for every pound of lard; then add a pint of proof-spirit, or whisky: cork the bottle firmly after its contents have been heated to 150 deg., taking it at the same time out of the water-bath, and agitate smartly till the phosphorus becomes uniformly diffused, forming a milky-looking liquid. This mixture being cooled, with occasional agitation at first, will afford a white compound of phosphorus and lard, from which the spirit spontaneously separates, and may be poured off to be used again, for none of it enters into the combination; but it merely serves to comminute the phosphorus, and to diffuse it in very fine particles through the lard. This fatty compound, on being warmed very gently, may be poured out into a mixture of Wheat-flour and sugar incorporated therewith, and then flavoured with oil of Rhodium, or not, at pleasure. The flavour may be varied with oil of aniseed, &c. This dough, being made into pellets, is to be laid in rat-holes. By its luminousness in the dark, it attracts their notice, and being agreeable to their palates and noses, it is readily eaten, and proves certainly fatal. They soon are seen issuing from their lurking places to seek for water to quench their burning thirst and bowels; and they commonly die near the water. They continue to eat it as long as it is offered to them, without being deterred by the fate of their fellows, as is known to be the case with arsenical doses. My friend in Derbyshire bought a pot of Mr. Meyer's rat-poison, and found it to be an analogous phosphoric preparation. The present mode of preparing it is the result of my own experiments, made with the view of diffusing phosphorus through a mass of flour and sugar, &c, without the risk of fire."

The paper in the Society's Journal, referred to by Dr. Ure, will be found in the third volume, page 428, and was communicated to the Society by Captain Stanley Carr, of Tüschenbeck, near Lübeck, in the duchy of Lauenburg. It may be an easy guide for those members of the Society who are desirous of following Dr. Ure's prescription, and may not have a thermometer at hand, to know that a temperature of 150° of Fahrenheit is equivalent to a degree of heat midway between that at which (according to Schübler) white-of-egg coagulates and white wax melts.

Mr. Miles, M.P., stated the success with which Captain Carr's remedy for destroying rats had been tried by himself and others in Somersetshire, and the extraordinary manner in which they came to eat it.

[The remainder of our report of the proceedings of the last and previous Weekly Councils, and of the two intermediate Special Councils, are unavoidably postponed.]

AGRICULTURAL CHEMISTRY ASSOCIATION.

The committee of management, in their Report, read at the half-yearly general meeting of the Association in January last, announced to the subscribers that Professor Johnston had shortly before then obtained premises for a laboratory, and had engaged several experienced chemists to assist him in his duties; and they expressed a belief that when the arrangements were completed, and when it became known to members of the Association, and to the public, that they were ready to begin work, full employment would be given them. The committee will now briefly narrate what has been done by themselves and by Professor Johnston to carry into effect the objects of the Association. Following the two great leading principles on which it was founded, namely, the diffusion of existing knowledge as to the application of chemistry to agriculture, and the enlargement of that knowledge, the committee will notice, first, what has been done in the way of lectures and other methods of affording information; and, secondly, what has been done by analytic investigations in the laboratory for the guidance of agriculturists and the advancement of the science. 1. It may be remembered that the committee in January last announced, that by way of an opening to the business of the Association, Professor Johnston had, at the solicitation of a number of leading agriculturists in the neighbourhood of Edinburgh, agreed to give three lectures on subjects of general interest. These lectures were accordingly given, and by the numerous assemblages of both landlords and tenants which they produced, proved the deep interest felt in the objects of this institution, as well as the earliest qualifications of Professor Johnston for the duties of the office he had undertaken. These lectures in Edinburgh were, after a short interval, followed by invitations from various local agricultural societies throughout the country to Professor Johnston to deliver similar lectures at the great towns with which they were connected. The subjects of lecture were the General Theory of Manures—Food of Plants—Uses of Manures—Mode of applying them—Methods of improving the Soil—the Benefit of Draining—the Use of Lime—the Qualities and Use of Guano—and the Feeding of Stock. The committee cannot doubt that one result of these visits by Professor Johnston to different districts was to stimulate and extend the desire among both proprietors and tenants for information on the subject of scientific agriculture. Within the last 12 months no less than seven or eight periodicals have been started in Scotland, and three of them within the last three months, exclusively devoted to the diffusion of information on the subject of Agricultural Chemistry and its practical used. Further, it deserves to be mentioned, that several of the parochial schoolmasters in the west of Scotland, perceiving the wishes of the farmers, that their children should imbibe some knowledge on these subjects, and at all events a taste for them, for which one lesson in the week might suffice, prevailed on Professor Johnston to compose a little treatise of a popular nature for their use; and one of them has recently applied to him to learn whether during the vacation of his school he may be permitted to attend the laboratory in Edinburgh, with the view of making himself more familiar with the science. That this is not to be traced to any fanciful idea of his own, is clear from the fact that the farmers of his neighbourhood have agreed to raise a sum of money among themselves to defray his expenses. If either this year, or in a future year, a sufficient number of such applications were made, the committee are happy to announce that Professor Johnston would be willing to give a gratuitous course of lectures to schoolmasters during three weeks of their autumn vacation. 2. The committee have the satisfaction of stating that the advantage of knowing something of the chemical nature of soils, manures, and other substances connected with farming operations is now becoming universally acknowledged and acted on; in proof of which it is enough to mention that during the last six months no less than 242 analyses, of one kind or another, have been performed by Professor Johnston and his assistants—being on an average more than one-and-a-half for every lawful day. When the delicate nature of many of these analyses is considered—some of them requiring many days for their performance, it will be acknowledged that in this department a very large amount of work has been accomplished. The subjects of these 242 analyses were as follow:—Soils, 90; Guano, 77; Waters, 25; Ashes of Plants, 14; Marls, 9; Miscellaneous, 27. The committee may here refer to some of the cases of analyses made in the laboratory, in order to point out to persons who are not members of the Association the practical benefits derived from such information. They will give some instances under different heads:—1. As to Analysis of Soils. Mr. F., a proprietor in the west of Scotland, having sent some samples of soils from his estate for examination, wrote as follows to Professor Johnston, after receiving the analysis:—"From your analysis of my soils it appears that they are deficient in magnesia and the phosphates, which accounts fully for the very beneficial effects of both these substances when applied to my soils as a manure.

It is a striking instance of the benefit that may be obtained from accurate analysis, showing that time may be saved by minute attention to the indications, and that the total failure of a crop may be prevented." 2. As to the Analysis of Guanos.—These several kinds of artificial guano, well known in the market under different names, and selling at as high a rate as natural guano, were during the last six months sent to the laboratory by members of the Association, that their agricultural value might be determined. In each case it was found that the prices charged were from one-third to one-half above the real value of the compound, and that in truth it would be better to spend the sum proposed to be laid out on these mixtures, in buying natural guano. It is hardly necessary to add that the advice so given was very readily followed. But the farmer must be on his guard against adulterations, even in what is sold as natural guano; for very recently a large quantity of a manure alleged to be genuine guano, was sent down to Dumfries for sale there, by one of the most respectable houses in London, which on examination was found to contain 75 per cent. of chalk, and to have been coloured by spent bark ground to a fine powder. The committee may farther mention under this head that a chemical manufacturer in Leith had a quantity of waste refuse, considered of no value, and which had accumulated on his premises—to the extent of about 100 tons—when it occurred to him to send a sample of it for analysis to Professor Johnston. He found that it contained substances extremely valuable as a manure, and recommended that it should be sold as such, at the rate of 3*l.* per ton. The result of this discovery has been, as may be supposed, eminently beneficial, not only to the manufacturer, but to the farmer, and in so far to the country at large. Further, the committee may refer, in illustration of the benefits derived from analysis, to a letter addressed to their secretary, by a member of the Association, and one who is himself an extensive farmer:—"Sir—In answer to your query, Whether or not, as a practical farmer, I have as yet benefited from the existence of the Agricultural Chemistry Association? I beg to say that my annual outlay for foreign manures, such as rape-dust, guano, bones, &c. upon an average of years is much about 150*l.* Previous to the existence of the Association, I was obliged to make my purchases, with no other means of judging of their probable genuineness or fertilising properties than by what their appearance indicated, but this last season I have invariably made my selection after obtaining a minute analysis of the different samples, and choosing the one most favourably reported on by the chemist, and, upon delivery of the stock had a second analysis performed, in order to satisfy me that it was not inferior to the samples from which I bought. I have no hesitation, therefore, in concluding that, by such means, I have been enabled to spend my money with a degree of certainty and satisfaction, which amply repaid me for the trifling expenses I incurred. In illustration, I may mention that part of a cargo from which I obtained my supply was found inferior to the rest by 10 per cent., but I, of course, was enabled, by the plan adopted, to demand compensation, which was immediately conceded. With regard, likewise, to the feeding of my live stock:—Having obtained from merchants samples of such foreign cake as they had, I submitted them for analysation to Professor Johnston, and from amongst them was enabled to select one which was offered to me as a manure, which I purchased at 85*s.* per ton. Having confidence in what it was composed of, I gave a regular supply to a breeding stock of black-faced ewes, at a very small cost indeed; and I am not exaggerating my probable gain, by that discovery, at from 50*l.* to 60*l.* The ewes, though feeding on stinted hilly pasture, were in a condition, at lambing time, never witnessed in former seasons. I have never as yet got any soil analysed; but I doubt not that much ignorance prevails among farmers as to the application of lime; and by simply obtaining a correct report from the chemist as to whether that ingredient is present to the necessary extent in the soil, one might determine upon a system of management, either most profitable to adopt, or save themselves an outlay which might be very needlessly and ruinously made. I trust many of the difficulties that presently embarrass practical men, will be gradually removed when the officer of your Association obtains a better acquaintance with practical agriculture, and thus better enabled to test, by the aid of science, those conflicting results which so often baffle and perplex the most experienced and enlightened farmers. What I have mentioned will, I hope, be considered a sufficient answer to your query. I am a rent-paying farmer, and must not lose sight of profit and loss. I have no idea of substituting mere theory for practical results, but I envy not the landlord or tenant who will refuse to consult a man of science, in order to see whether or not the art might be advanced, by which they not only live, but for its improvement are responsible to the whole community."

Whilst thus explaining the great practical benefits afforded by chemical analysis, the committee would beg to remind subscribers that in applying to Professor Johnston it is material that the party should inform him of the precise object he has in view, seeing that testing for a particular ingredient can be had for 3*s.*, whilst an analysis ascertains all the ingredients, and costs at least 12*s.* 6*d.* To assist subscribers in this matter, the committee intend to draw up and circulate among them a list of charges, with such explanations as will remove all difficulty. And here the committee would take the opportunity of adverting to the cheapness of the terms on which these benefits may be obtained through the medium of the Association. Most persons not being aware of the labour and cost attending chemical analysis, [illegible] that [illegible] been [illegible] by Professor Johnston during the last six months. These expenses, consisting of travelling expenses, attendance, assistants, chemical apparatus, &c. &c.—amount to 250*l.*, which, with the 242*l.* 10*s.* previously paid during that year, make 492*l.* 10*s.* of the sum received, thus leaving a balance on the hands of Professor Johnston of 193*l.*, and intimating to that effect his income out of the subscriptions received by the committee of management. The laboure has been useful, however, in another way than in merely affording analyses to subscribers. It has been employed also in extending our knowledge of the science of Agricultural Chemistry, of which the committee might give several interesting illustrations. But here they would be out of place, and other means will be adopted for bringing them before the public. It appears, however, from some of these researches that the ash of plants varies much more in composition according to the soil and manure in which they are grown, than has hitherto been supposed; and that more is really within the power of the skilful farmer, in the way of modifying the nature of the vegetable food he raises, than without these researches could have been expected. In Mr. Johnston's Report, lately distributed among the members of the Association, mention was made of the composition of Turnips raised with guano and with farm-yard manure; some experiments recently made with the same Turnips, under the direction of Lord Blantyre, have shown that they not only differ in composition, but have very different feeding properties, thus showing the connection between the manure employed and the value of the food raised.—Sir John Hope moved that the meeting approve of the Report now read, and give their best thanks to the committee of management for their services during the last six months.—Mr. Scott of Craiglockhart seconded the motion. Every one (he said) must be convinced that the institution had done a great deal of good to practical agriculture; and especially in relation to the testing of guano. A subject to which he was desirous of alluding was the disease of Potatoes. It extended this year further than it did the last year, and if it continued to extend in the same proportion in which it had done during the two last years, the consequences to the country would be most disastrous. The diseases, which were three in number, he considered to be of so many several kinds, and he thought it would be extremely desirable for the Association to endeavour to throw some light upon the subject. Many of the most careful and most experienced agriculturists were at this moment suffering from it to a very great extent, notwithstanding the exercise of every precaution which skill and experience could suggest.—Mr. Milne, advocate, as one of the committee of management, thanked the meeting for the approval of the Report, and expressed satisfaction at the manner in which Mr. Scott, a practical farmer, had expressed his approbation of the way in which they had brought the Association to its present state. Before sitting down, there were two points to which he was desirous of calling the attention of the meeting. One was the advantage of obtaining analyses of manures; the other the advantages of agricultural schools. In regard to the first, it was inconceivable what a vast sum of money was expended by the agriculturists of this country for manures. They all knew that farm-yard manure was generally insufficient for the purposes of cultivation, and, therefore, recourse must be had to other manures. One farmer expended 150*l.* a-year on foreign manures; and he (Mr. M.) held in his hand a note of the sums expended on an average in the year for manures, as follows:—Bone-dust, 91,755*l.*; rape cake and rape-seed, 169,331*l.*; guano (being the amount imported, not for the country at large, but to Liverpool alone, in one year), 59,240*l.*; being a total of upwards of 320,000*l.* These were the sums expended in manures; and if they were to believe the accounts in the newspapers, which stated that 300 vessels are to be sent to bring home guano, they would soon have an expenditure by the farmers of several millions for this article alone. Now, it was of the greatest importance to check adulteration in guano, because it was hardly possible to take up one of the new publications devoted to this subject, without seeing the enormous extent to which the industrious farmers of this country were defrauded by its adulteration. He had brought with him a number of the *Gardeners' Chronicle*, edited by Professor Lindley, a periodical which was of essential service to agriculture. In this publication many places were mentioned where manures were sold, containing hardly one of those substances whose specific virtues were required. (Mr. Milne then read several extracts from the publication in question, detailing cases at Hull, in Cheshire, and Dumfriesshire, in which guano and bone-ash were sold as pure, although they were adulterated to an almost incredible extent with other substances, either of a noxious nature, or useless as manure. It was a remarkable fact, he continued, that while England had been inundated with these spurious mixtures, Scotland had been in a great measure free of them; for it appeared that of the seventy-seven analyses of Professor Johnston, not one of them had been spurious. Whether or not these dishonest dealers were afraid of venturing upon our soil, knowing that a check existed, and that there was, therefore, a risk of exposure, he did not know; but such was the fact. He mentioned this to show of what consequence it was to the farmers, who spend such large sums upon manures, to have the means of protecting themselves against these frauds, which had the effect of causing them not only to throw away their money, but also to injure their land and their cattle.—A motion for a vote of thanks to Mr. Coventry was then unanimously agreed to, and the meeting then broke up.—*Agricultural Journal of the Caledonian Mercury Courant.*

FARMERS' CLUBS.

Burton-upon-Trent.—At the usual monthly meeting, Mr. Tunbury read a paper on "The Application of Steam to Agricultural Purposes." He had erected a steam-engine on his farm, and had applied its power to a threshing-machine, a chaff-cutter, and a corn-crushing machine, and had connected with it an apparatus for the steaming of cattle provender. The outlay had been considerable, and would have been better repaid on a larger farm, as the engine and machinery was capable of doing three or four times the work he required it to do. Still, taking into consideration the saving he had effected in threshing his corn, and in a more economical plan of feeding his cattle and horses through the winter, the result had been on the whole very advantageous to him. The whole outlay for his six-horse-power engine, and the rest of the machinery, was about 180*l.* The interest on this sum, together with an allowance for wear and tear, he calculated at 15*l.* 15*s.* He had used his threshing-machine 23½ days. He required, on an average, the labour of one man and four women, besides his own superintendence, and his coals cost about 2*s.* 6*d.* each day. The whole expense in labour had amounted to rather more than 8*l.* Reckoning Wheat at 5*d.* per bushel, Barley at 2*s.* per quarter, and Oats at 1*s.* 8*d.*, the quantity of corn he had threshed would have amounted to rather more than 36*l.* if threshed by hand. The saving effected by the threshing-machine had therefore more than repaid the whole annual expense of the outlay; but in the cutting and steaming cattle food he had, as he thought, saved much more. With regard to the steaming of food there were various opinions. The experiments which had been tried seemed to prove that no advantage attended it in the case of grain or roots; and though it was admitted that the steaming of dry fodder enabled cattle to extract a larger portion of nutriment from a given quantity, yet it was doubted whether the cost of the process did not outweigh the advantage gained. He was of opinion that where the cost could be reduced to so insignificant a sum as by his method, the advantage was great. The effect of steaming was not to alter the nature of the food: it did not convert poor food into rich: its simple effect was to render more of the nutritious part of the food digestible. By bruising grain, every particle was exposed to the action of the juices of the stomach; and cattle could break down the substance of roots and green crops thoroughly with their teeth; but in dry fodder some part of the nutriment escaped the action of the stomach, because the fibre could not be thoroughly broken up by mastication. By cutting fodder into short lengths, and steaming, it was rendered tender, and was made to resemble green food. By steaming, both hay and straw might be made more nutritious, and we might substitute a portion of straw for hay, and still keep cattle doing as well as on dry hay alone. He thought it a great advantage to consume a good part of the straw as provender, provided you could do so, and yet keep cattle in condition. The necessity of mowing pastures to a large extent was thereby avoided; it was unprofitable to exhaust pastures by mowing them, and to repair the waste by manure. The manure would be better employed on the arable land, and the pasture would yield a better profit by having its produce consumed on the ground. During the last winter he had 90 head of neat cattle and horses, and he fed them during the whole time on steamed hay and straw. He had a simple apparatus for steaming attached to the boiler of his engine, by means of which the chaff was steamed with great quickness. The coals for the work of the engine and for the steaming, each time cost 1*s.* He cut and steamed 600 or 700 strikes twice a week, and the labour of two men for two hours was sufficient. The cost was not, therefore, more than 4*s.* a week for steaming the food of 90 head of stock. Up to the 14th of February he kept all his stock on one-third hay mixed with two-thirds straw. After that time, finding his cows get in low condition, he used half straw and half hay, and gave the milking beasts a foddering of hay morning and night. As they calved he added a pound of linseed to their steamed food. With this diet his cows grew fast and got into milk as well as he ever remembered. Contrasting his consumption of hay in this and former years, he calculated that he had saved 40 tons; but he thought that if he had used 10 tons more it would have been better, and he therefore set down 30 tons as his saving. The difference between the consuming price of 30 tons of hay and the 30 tons of straw which supplied its place, reckoning hay at 3*l.* 10*s.*, and straw at 1*l.* 5*s.*, would amount to 67*l.* 10*s.*, while the expense of cutting and steaming amounted to less than 5*l.* A very general opinion was expressed that it was more advantageous to have Barley threshed by the flail: when thrashed by machine the pile was cut off so close that it turned out much less measure. Mr. Payne would, notwithstanding the greater weight of samples threshed by machine, prefer Barley threshed by flail at 2*s.* per quarter more, for the purpose of malting. Except for very extensive farms, it was thought that the great outlay required for steam-power, rendered it more expedient to use either the flail or horse-power machines, unless the landlord would be at the cost of erecting the necessary buildings.

Darlington.—At the late monthly meeting of this Club, the subject for discussion was, The comparative Advantages of Stall and Pasture-feeding for Draught Horses and other Cattle during Summer; with the best and most profitable Green Fodder for Soiling or Stall-feeding. A

discussion ensued, during which the whole subject was brought under review. When the meeting was in opinion that it was in most respects decidedly preferable to soil draught horses with green food during summer, but more particularly in consequence of their being able to feed in a much shorter space of time on green Tares or Clover laid before them, than what they could do if turned out to pasture. They would obtain more rest, would not be teased by flies and other insects, and by those means would keep in better condition; besides, a much less quantity of land would keep a team of draught horses or any other heavy cattle when confined in the stall or yard, than would be required if they were pastured upon the land. A greater quantity as well as a better quality of manure would also be produced by soiling, for in dry weather during summer the cattle droppings in the pastures are dried by the sun and wind, so that a considerable portion of the soluble matter evaporates and is lost, whereas the manure produced by soiling in-doors can be preserved of good quality in much greater quantity, and can be applied to the land with greater advantage at suitable seasons. As to milk cows and feeding beasts the Club were not so unanimous with regard to soiling them during summer, and further experience seemed to be wanting in soiling heavy-horned cattle. Some doubts were also expressed by one or two members as to the suitableness of green Tares or Clover for milch cows, they believing that this kind of food had the effect of causing the butter produced therefrom to be light and oily, and also that green Tares produced thin and poor milk; however, the majority were in favour of soiling all heavy cattle during summer, believing by that means that a much greater number of cattle might be kept on a farm than what could be done by turning them upon the land to depasture. With regard to the best and most profitable kind of green food for soiling, the unanimous opinion was that winter and spring Tares, in conjunction with Clover, with a little Italian Rye-grass sown amongst it, were the best and most profitable for soiling in this part of the kingdom, but that Clover, so far as it could be made available, was preferable to Tares, it being generally believed that draught horses fed upon green Clover, stood their work, and kept their condition better than when fed upon green Tares; whilst, at the same time, Tares are believed to exhaust the land more than Clover. At the conclusion of the discussion, the secretary laid before the meeting 21 handsomely bound volumes of "The Journal of Agriculture," and Prize Essays and Transactions of the Highland Agricultural Society of Scotland, which were presented to the Club by Lord H. Vane, M.P., and John Bowes, Esq., M.P., representatives of South Durham. A unanimous vote of thanks was awarded to them for this very valuable donation of books, and for their kindness in encouraging and supporting the interests of the Darlington Farmers' Club and the science of agriculture generally. The subjects fixed for discussion at the next monthly meeting of the Club are—The best Method of making and securing Hay; and the best Season of the Year for applying Manure to Grass lands.—*Yorkshire Gazette.*

East Cornwall.—At the late meeting of this Society F. Rodd, Esq., of Trebartha, detailed some experiments he had made on manures of different kinds. North-hill Lower-park, the subsoil of which is slate and spar, value about 18*s.* per acre, he had manured with Turnip-tops and roots as a manure for Wheat. It was ploughed at Christmas, 1841. One portion was tilled with Turnips, and another with Potatoes, the whole being equally manured with a compost of lime and earth, with the addition of some farm-yard dung. The produce was about 240 bushels of Potatoes and about 30 tons of Turnips per customary acre. In November, 1842, the Potatoes and Turnips were carted away, first cutting off the tops and roots of the latter, and laying them in the furrows after the plough, during the process of preparing that portion of the field on which the Turnips had grown. The produce of Wheat the following year was, on the Turnip ground, 36 Winchester bushels of grain, and on the Potato, 28 bushels per customary acre. On a small portion of the Turnip ground, no Turnip leaves were laid, and on this part the crop of Wheat was decidedly inferior to the part so manured; while that in the Potato ground was inferior to both. The whole of this field was now in Barley, and there was a fine and promising crop throughout, but presenting no visible difference in favour of the Turnip ground. Outer North-hill-park, adjoining the last field, and similar to it in all respects, was in 1842 in Grass, and treated precisely the same as the former—one part of it being filled with Turnips and the other with Potatoes. In 1843 the leaves of the Turnips were laid as before in the furrows of the Turnip ground preparatory to the Wheat tillage. The Wheat now growing on the Turnip ground maintains the same apparent superiority over that on the Potato ground, as shown in the previous instance. A portion, however, of the Wheat on the Potato ground received, in the spring of the present year, a quantity of undiluted liquid manure, in the proportion of 46 hogsheads to the acre. The Wheat thus treated is far superior in its growth and appearance even to that grown on the Turnip ground and manured with the tops. But the plant on which the liquid manure had produced the greatest effect, was the Cabbage, which in some instances had been forced by it to double and even treble its ordinary size, not to mention the copious after-crop of sprouts from the old stump. An experiment on the effect of folding sheep on Wheat had been tried on a field of his, the subsoil of which was spar and slate, worth 1*l.* per acre. In 1843, it was ploughed down and prepared for Wheat, manured with 20 loads of dung, mixed with double that quantity of earth, and tilled in the following October. In March, 1844, he folded fourscore sheep, and twelve cattle nightly in the proportion of from 600 to 1000 sheep to the acre, changing their ground every night, and turning them into Grass pasture by day. The difference between the Wheat grown on the folded ground, and on the portion not folded, was very manifest. Specimens of Wheat effected by the foregoing modes of management were produced, fully confirming the statements made.

Netherens.—In May 1843 it was resolved by this Club that the best method of keeping Clover-seed for a longer period than a year was as follows:—The seed should be made thoroughly dry, placed in casks about three-fourths full, tightly stopped, and frequently rolled during the time it is kept. In June it was considered that drills from 15 inches to 20 inches apart on a flat surface, and 27 inches on ridges, would be best for drilling Swede Turnips, and that a pint and a half of good seed would be enough per acre. In December, the best sorts of Wheat for early and late sowing was the topic introduced, when it was considered that the best sorts for early sowing in this neighbourhood are Honeyball and Brown's Prolific; and for late, Redstraw or old Lammas.

Stevenage.—At the late meeting of this Club, Mr. W. Griffithes, being called upon, read a paper on The best Method of Harvesting Corn, from which the following are extracts:—"I think the kind of Wheat, whether red or white, and the difference of soil upon which it is grown, has something to do with the state of ripeness in which it should be cut, believing, from the little experience I have had, that Wheat grown upon strong soil—Wheat and Bean-land—is more injured in appearance of sample by being allowed to get ripe, than Wheat grown upon light soil, or what is termed Turnip and Barley-land. I find my Wheat, which is cut first, and consequently generally greener than that succeeding it, the best sample, and most pleasing to the millers, whose taste in this particular I endeavour most especially to gratify. I should say the best time to cut Wheat is when it is arrived at that state of ripeness sufficient to admit of its being cut without causing the Corn to shrivel or contract into wrinkles, by which we may secure plump, well-filled culms, with a bright thin skin upon them. I have not observed that white Wheat, in the sale of it, is so much affected by being suffered to get quite ripe, as red Wheat is; but as the sorts are frequently grown upon different soil, the advantage, if any, may arise from that cause. As to the manner of cutting Wheat, whether with scythe, or broad hook, or sickle, I consider the scythe and broad hook equal in many respects (except in tying up of the sheaf, which is not always done, I had nearly said, could not be done in so workman-like a manner after the former as the latter). The land from which the Wheat has been cut with either broad hook or scythe, certainly gains many advantages over that from which the Wheat has been cut with the sickle, the chief benefits of which system seem to consist in the appearance and handiness of the Corn after it is cut, which is certainly better in many respects. With regard to Barley, to the production of which a large portion of the land in this neighbourhood is appropriated, and the quality of which may be affected by its state of ripenness when cut, I am of opinion that it should be allowed to get nearly ripe; it is injured by being cut before being ripe enough. Barley is also much affected by the after management in the field in wet weather; and as situation has much influence over that, I would rather leave to every person's judgment the selection from the different plans adopted of what suited his circumstances. The waggons used for carrying grain in harvest time have been (the generality of them) built with the view of carrying much heavier loads, and consequently are much heavier and stronger than would be required for the purpose of carrying grain in the straw; but if waggons were built for the purpose, and so constructed that the fore-wheels would turn under the chest, as some at present do, which enables them to be turned nearly as short as a cart, I think they would then be the best adapted for that purpose in this country. In some parts of England, and the whole of Scotland (whence so many agricultural wonders come), carts are used solely for that purpose, I believe; but from what I have seen done with carts, and when used by their advocates too in this neighbourhood, at harvest work, I make no wonder that more converts to the system are not made. As regards the best place for making ricks, whether in the field or rickyard, I cannot conceive it to be good policy to draw grain a long distance home in a very busy time, however pleasurable the sight of a well-filled rickyard may be, as there is generally more loss of time when waggons have a long distance to go and come than when ricks are made in the field, from which they can be removed in winter at much less expense than in harvest. Thus have I gone over the different subjects intrusted to me, and though in a very inefficient manner, still let me beg of you to make up the deficiency by your discussion and elucidation of them, so that the subject may not suffer on my account.

'If a better system's thine,
Impart it frankly, or make use of mine.'"

The paper was received with much satisfaction by the meeting, when an animated discussion arose amongst the members present, and it was finally resolved "That it is advisable to cut Wheat generally a little before it is ripe, and that the best manner for cutting, on an average of years, is with the sickle; that waggons of a light construction are preferable to carts, and that the best place for making ricks when at a distance is in the fields."

Reviews.

Lectures on Agricultural Chemistry and Geology.—By James F. W. Johnston, M.A., F.R.SS., L. and E. Reader in Chemistry and Mineralogy in the University of Durham, &c. William Blackwood and Son, Edinburgh.

It is not one of the slightest merits of this work, that many of the early Lectures published in it, were actually delivered to an Agricultural Society—to farmers, in fact, "most of whom possessed no knowledge whatever of scientific Chemistry or Geology. They commence, therefore, with the discussion of those elementary principles, which are necessary to a proper understanding of each branch of the subject. Everything in such Lectures, which is not—or may not be—easily understood by those to whom they are addressed, is worse than useless."*

And thus, while it is a complete work on Agricultural Chemistry, giving all the explanations and suggestions which can be founded on the science in its present state, it may at the same time be understood by any one altogether ignorant of the science, who will take the trouble to read it through from the beginning.

The first Lectures contain the materials by which, in those which follow, the details of agricultural management are explained, and improvements in it are suggested. Thus, one of the last subjects treated of is the very important one—the conversion of vegetable matter into the substance of animals. This properly occupies the latest attention of a lecturer on Agricultural Chemistry, as it is itself one of the *ultimate* objects to which the whole practice of farming tends. The following summary of the views of Chemists on this subject, is extracted from the last Lecture of the series:—

"1. It appears that all vegetables contain ready formed—that is, form during their growth from the food on which they live—those substances of which the parts of animals are composed.

"2. That from the vegetable food it eats, the animal draws directly and ready-formed the materials of its own body—phosphates to form the bones, gluten, &c., to build up its muscles, and oil to lay on in the form of fat.

"3. That during the process of respiration a full-grown man throws off from his lungs about 8 oz., a cow or horse five times as much, of carbon every 24 hours; and that the main office of the starch, gum, and sugar of vegetable food is to supply this carbon. In carnivorous animals it is supplied by the fat of their food, in starving animals by the fat of their own bodies, and in young animals, which live upon milk, by the milk sugar it contains.

"4. That muscles, bones, skin, and hair undergo a certain necessary daily waste of substance, a portion of each being removed every day and carried out of the body in the excretions. The main function of the gluten, the phosphates, and the saline substances in the food of the full-grown animal is to replace the portions of the body which are thus removed, and to sustain its original condition. Exercise increases this natural waste and accelerates the breathing also, so as to render necessary a larger *sustaining* supply of food, a larger daily quantity to keep the animal in condition.

"5. That the fat of the body is generally derived from the fat of the vegetable food—which fat undergoes during digestion a change or transformation by which it is converted into the peculiar kinds of fat which are specially fitted to the body of the animal that eats it. In carnivorous animals the fat is derived directly from the fat of their food, which is, in like manner, changed in order to adapt it to the constitution of their own bodies. In cases of emergency it is probable that fat may be formed in the animal from the starch or sugar of the food.

"6. In the growing animal, the food has a double function to perform: it must *sustain* and it must *increase* the body. Hence, if the animal be merely increasing in fat, the food, besides what is necessary to make up for the daily waste of various kinds, must also supply an additional proportion of oil or fat. To the growing animal, on the other hand, it must supply also an additional quantity of gluten for the muscles, and of phosphates for the bones. If to each of a number of animals equal quantities of the same kind of food be given, then those which require the smallest quantity of food to sustain them will have the largest proportion to convert into parts of their own substance. Hence, whatever tends to increase the sustaining quantity—and cold, exercise, and uneasiness do so—will tend, in an equal degree, to lessen the value of a given weight of food, in adding to the weight of the animal's body. To the pregnant and to the milk cow the same remarks apply. The food is partly expended in the production of milk, and the smaller and leaner the cow is, less food being required to sustain the body, the more will remain for the production of milk.

"7. Lastly, that the quantity and quality of the dung, while they depend in part upon the kind of food with which the animal is fed, yet even when the same kind of food is given, are materially affected by the *purpose* for which the animal is fed. If it be full-grown and merely kept in condition, the dung contains all that was present in the food, except the carbon that has escaped from the lungs. If it be a growing animal, then a portion of the phosphates and gluten of the food are retained to add to its bones and muscles, and hence the dung is something less in quantity, and considerably inferior in quality to that of the full-grown animal.

"So it is in the case of the milk cow, which consumes comparatively little in sustaining her own body, but exhausts all the food that passes through her digestive

* Preface to Professor Johnston's Lectures.

organ for the production of the milk which is to feed her young. The reverse takes place with the fattening ox. He takes little else from the rich additional food he eats but the fat with which it is intended that he should invest his own body. [illegible] for the most part, lost in his stertorous, and hence the hoarseness and [illegible]

[illegible]

Potato Blossoms.—Early in the month of last season was divided [illegible] one side and one-third on the other, and pulling off the blossoms from the latter third, thereby to [illegible] the whole field, [illegible] theory with the other the blossom-bearing stalk takes [illegible] that it did not do more than this third, but [illegible] and also induced [illegible] the flowering habit of the field. This third was planted in the middle of April, the remainder towards the end of that month. Those from which the blossoms were pulled were much more productive, and also produced [illegible] in quality and appearance to the other portion of the field. Being [illegible] particular in the selection of my seed, I had them sorted as usual, when drawing home in winter, into separate pits, those for seed being put in small pits, two feet wide, and those for sale or consumption in pits five or six feet wide. The seed put in the small pits for seed was selected from the two-thirds spun in the end of April, as I always heard it recommended to use the late rather than the early seed; this sorting, remember then, was from the Potatoes from which no blossoms were pulled last season. This season we commenced planting on the 20th of April, from the seed so selected and pitted in the small pits; but as the seed was short, we opened the large six-feet wide pit, and sowed nearly as much more; the only difference beside the seed was, that what was allowed to blossom last season had fine, well-rotted, well-prepared dung, while the latter got manure recently gathered from the yard, fresh and strawy; the difference now, however, is very great—those from which the blossoms were taken having [illegible] stronger, and far outstripping the other, although from the same pits, and were taken from the very best in the neighbourhood. These are sound tubers, but not one from the unblossomed seed, which were [illegible] when accidentally cut with the spade, and [illegible] the others, [illegible] equal; but this cannot be said of the others. In a few places where the seed of the unblossomed ones happened to be dropped, and the [illegible] of the drill, exposed to the great drought of this season, it grew and took [illegible] sprung up, [illegible] round the set into the ground, but the others, wherever displaced, shrivelled up and decayed. Thus it is [illegible] that good sound seed will not be [illegible] or prevented from growing by almost any neglect; while tainted seed, be it ever so sound in appearance, can scarcely be kept alive even with the greatest care. I have great care in planting and manuring [illegible] and yet the crop grows slowly, [illegible] it is an evidence that the seed was not the soundest, and that but for the care taken they would not have grown at all. To the weakness of the seed all failure may be traced; and therefore to grow and preserve the seed should be the chief [illegible] in Potato culture. So far for the [illegible] result; and in theory I believe botanists would advise that to pull off the bloom will add to the tubers below, [illegible] to the quality and soundness, the above, [illegible] satisfies me. You are aware of [illegible] being kept alive for two, three, or more years, by depriving them of the bloom as it appears: the above sort of [illegible] does not generally bear berries; still if keeping the blossoms off prolongs the existence of the plants, as it did with me last season, they will, of course, during the growing season, be adding to the quantity and quality of the tubers below; for of two objects to be attained by a plant—that of bearing seed above, and ripening tubers below—it will surely do one much more perfectly if its energy be confined to it. Some writers affirm that excessive seed-bearing produces the curl in Potatoes, and instances like effects in the animal kingdom. It is remarked, also, that in dry seasons bulbous and tuberous roots are more apt to bear seed; and perhaps it were well if some persons would take the trouble to look back and see if the failure in Potatoes did not generally follow previous dry summers. This being a dry summer, if the above remarks contain any truth, it were well if people would devote some attention this way, and give employment to many poor children; and indeed if the matter be of the importance that I think it is to the country at large, the committee of the Irish Agricultural Improvement Society ought to be directed this year to try the experiment on a large scale. I am so entirely in favour of it, that I shall not try any *comparative* experiment myself, but will destroy all the blossoms with as much care as I would the weeds. I pick the blossoms off before they expand; the flower-stalk being then brittle, it is much more easily performed.—*E. T., in the Dublin Farmers' Gazette.*

Utility of Experimenting.—Shellfish a valuable Manure.—Last year we stated the case of an intelligent gentleman, who had planted Beans in the same row with Potatoes, and the experiment, we are happy to say, succeeded so well that the produce, when carefully measured, exceeded expectation—36 Winchester bushels of Beans, in addition to 12½ tons of Potatoes per acre, and both articles of superior quality. In agriculture, fortunately, as in [illegible] whatever can be done in a corner to the disadvantage were it desired, of the surrounding community, and accordingly, so many persons, including [illegible] watched the minister's new-fangled [illegible] that [illegible] applied were, however, too late to save the lives of Chapman and his two children, who sank under the effect of poison, which [illegible] absorbents, and the blood impregnated with the virus. One other [illegible] survive [illegible]

[illegible] with proper precaution, the disease may be [illegible] together, [illegible] I am [illegible] [illegible] extent, the [illegible] ago I tried some experiments to prevent smut, which seemed [illegible] and [illegible] but certain [illegible] morning too late. I shall be happy to state them.—

November, 1822. I selected three bushels of Wheat, which I had grown that summer, and which was exceedingly smutty; put to remove it still more, as I had a quantity of smut-ball rubbed into it, until the whole was much blackened. The lot was then divided into nine half bushels, and having dissolved half a pound of blue vitriol in boiling water, the Wheat was pickled as follows:—No. 1.—Immersed in the pickling water for three hours. No. 2.—Washed and skimmed well, its own bloom, then immersed in the pickling water as above. No. 3.—No preparation. No. 4.—Washed and skimmed well until clean. No. 5.—Washed and skimmed as above, then sifted quicklime over it, and mixed a quarter of a pound of salt with it. No. 6.—Pickled in the mode usually adopted, with a mixture of lime, salt, and water. The seed was sown the following day on a Clover ley, in six separate ridges, each 113 yards long by five yards wide, half a bushel to each ridge, being at the rate of near five bushels per acre. Appearance of the braird.—Nos. 1, 2, and 5 came up this morning to be at the rate of only two bushels per acre. No. 6 appeared to be at the rate of about 2½ bushels per acre. No. 4 appeared to be at the rate of about three bushels per acre. No. 3 appeared at the rate of about 4 bushels per acre. Sept. 5th, 1823.—The whole was reaped each lot being carefully kept separate, and the result proved as follows:—No. 1.—Found only two smutty ears in the whole ridge, which notwithstanding the care taken, might have come from an adjoining ridge. No. 2.—Had several smutty ears in it. No. 3.—From 30 to 40 black ears in the ridge. No. 6.—About a 20th part smutty ears. No. 4.—About a 5th part smutty ears. No. 5.—About one-half smutty ears. From which it appeared that pickle, coupled with washing and skimming, proved to be an effectual cure, even to a sample of the description sown. Ever since, I have invariably used vitriol, and have found from 20 years' experience on upwards of 100 acres of Wheat annually that one pound to each of Wheat will prevent the disease, as I have never had smutty Wheat since. I believe the cure was effected in the above, by destroying the vegetative powers of the diseased seed; for it will be observed that the produce was clean in proportion to the thickness of the plant. Hence the produce was black in No. 3, which had no pickling, and half the seed appeared to have been destroyed in No. 2, to produce a perfect sample. The grain must be seriously affected by the disease before such beneficial effects would ensue from washing and skimming; but I am inclined to think that soil and season have considerable influence upon it. Some years ago I was requested to value 40 acres of Wheat in this neighbourhood, growing upon wet, poor land, and upon a very careful examination of it I found one-third consisted of smutty ears, and my calculation of the value was made accordingly. The owner informed me that the same seed had that summer produced on healthy land in the western end of this county a good sample. We do not now wash and skim, but simply use vitriol mixed with water, and a small quantity of quicklime to dry it.—*Report of the Cardiff Farmers' Club.*

Guano.—Since guano as a manure has for some time excited great attention among agriculturists, it may not be uninteresting to some readers to learn the opinion of a foreigner given a hundred years ago. The work from which I extract it is entitled, "A Voyage to South America, undertaken by command of the King of Spain, by Don George Juan, and Don Antonio de Ulloa." This journal bears date 1741. They say nothing about guano exhausting the land; but their remark that it is not used for Wheat and Barley is worth attending to. The translation from which the passage following is extracted was published at London in 1760:—"The lands in the jurisdiction of Chancay, like the other parts of the coasts of Peru, are manured with the dung of certain sea-birds which abound here in a very extraordinary manner. These they call guanoes, and the dung guano, the Indian name for excrement in general. These birds, after spending the whole day in catching their food in the sea, repair at night to rest on the islands near the coast, and their number being so great as entirely to cover the ground, they leave a proportionable quantity of excrement. This is dried by the heat of the sun into a crust, and is daily increasing, so that notwithstanding great quantities are taken away, it is never exhausted. Some will have this guano to be only earth endowed with the quality of raising a ferment in the soil with which it is mixed. This opinion is founded on the prodigious quantities carried off from these islands, and on the experiment made by digging or boring, by which the appearance at a certain depth was the same as at the superficies; whence it is concluded that the earth is naturally endowed with the heating quality of dung or guano. This would seem less improbable did not both its appearance and smell prove it to be the excrement in question. I was in these islands when several barques came to load with it; when the insupportable smell left

used in the fields sowed with [illegible]

[illegible] almost [illegible]

[illegible] entirely [illegible]

[illegible] Indian way [illegible]

[illegible] and [illegible]

[illegible] the [illegible]

[illegible] liquid manures. I shall [illegible]

[illegible] to the [illegible]

[illegible] quaintness which [illegible] generally [illegible]

[illegible] plain [illegible] to plain people.

[illegible] the [illegible] tank, watering-cart, and [illegible] from my system, but attach the [illegible] they [illegible] actually work in [illegible] I have the more hope that my plan will succeed, as [illegible] generally do not call in the [illegible] liquid manures will not do when applied in [illegible] perfectly plain to [illegible] liquid manure, if spread upon an impervious [illegible] soil, as [illegible] is not retained long enough in [illegible] taking place, or for the roots of the [illegible] it up in its fresh state. It [illegible] liquid manure, and runs off nearly in the same state, but upon it to a soil rich in [illegible] and [illegible] upon, and on which [illegible] vegetable [illegible] never fails of its extraordinary [illegible] fertilising principle of the manure is [illegible] The water by the decomposition and [illegible] of the carbon or humus—or call it what you will—in the soil, and [illegible] there till absorbed by the rain, which in the form of dew, or taken up by the plants, and by [illegible] and [illegible], or embodied in the growing plant [illegible] liquid manure is at once [illegible] up and [illegible] in the structure of the plant, the water being [illegible] by the leaves, and the organic matter built up [illegible] The [illegible] of administering liquid manure [illegible] perfectly [illegible] state is probably the best of any, were it not for the continued care and attention, and [illegible] expense necessary in supplying our crops with [illegible] in their stages throughout the [illegible] were we certain of the exact [illegible] of the [illegible] stored up in their stems, but which, probably, in [illegible] the water will naturally take up and carry to [illegible] Now, therefore, cannot apply our liquid manures on the best principle, on account of the expense, we may [illegible] the next best plan, that of decomposing them by the aid of [illegible] vegetable matter; and this can happily be done to great perfection by reducing the vegetable matter to the state of carbon or charcoal. The way we [illegible] is—After having laid in a good stock of [illegible] which we make from Peat, as being trifling in expense, easily pulverised, and withal an excellent manure of itself—we divide a shed, or any other building, into two compartments, one of which we make water tight, by puddling the side walls with clay, to the height, perhaps, of two feet, and separate from the other compartment by a low water-tight wall or boarding. This is the fermenting tank, which is filled half or three parts full of pulverised carbonised Peat, and the liquid manure from the byre, stable, pig-styes, &c., &c., directed into it. This is allowed to remain mixed up with the carbonised Peat for three or four weeks, till the decomposition seems about completed, being occasionally stirred about after the composition has become about the consistency of gruel. The whole is then laded over the low partition into the second floor, which is also three parts filled with carbonised peat; and as this second floor is meant merely as a filter, we have it lower on one side than the other, by which means, in the course of a day or two, the carbonised peat is left comparatively dry. The water having passed off at the lower side in a crystal stream—fit for tea or toddy to the most fastidious—the first or fermenting floor is again filled as before, and the contents of the second floor, if considered saturated enough, is then shovelled up into a corner, and allowed to drip, and further dry, till used, which may be either immediately, or at the end of twenty years, as scarcely anything will affect it, if not exposed to the continued washing of rain water, or exposed to the influence of the roots of growing plants. By being thinly spread on a granary floor it soon becomes perfectly dry, and suited to pass through drill machines of all descriptions. The mixing of the carbonised Peat with the liquid manure on the first or fermenting floor, it will be observed, is for laying hold of the gaseous matters as they escape during the fermentation; perhaps other substances may effect this more effectually, but none so cheaply. I think by this plan it will be obvious to every one that a great many desiderata are at once obtained. In the first place, you get rid of about 900 parts out of every 1000 of the weight and bulk of manure by the expulsion of the water, while at the same time you link all the fertilising properties contained in it to one of the most lasting vehicles you can possibly think of—[illegible] and [illegible] the [illegible] which [illegible] [illegible] [illegible]

season proves it to be in high estimation. We may be allowed to add a few words as to the *modus operandum*. It is to be understood that the manure is to be placed in the drill so as when covered its *surface* may not be less than three inches below that of the soil. The coulter of the sowing machine is to be placed so as to penetrate to the above depth, and deposit the seed on the *top* of the manure. The pressure of the roller which follows causes the earth to subside, generally about an inch and a half, at which depth it then leaves the seed, so that, in reality, the actual depth of deposition is not so great as, at a glance, the readers of Mr. Wells' former communication would be apt to imagine. We talked over the matter with a gentleman whose experience qualifies him to give a correct opinion as to the merits of the system, and with this explanation he thinks it more than probable its practice will be generally and profitably adopted.—*Ed. A. G.*]

Guano.—The Island of Ichaboe.—We have been favoured with the following "Remarks on the Island of Ichaboe, and the adjacent Coast of Africa," which we copy almost literally from the notes of the master of a vessel who has repeatedly visited them, and is well qualified to express an opinion on the subjects on which he treats. The island of Ichaboe, which has caused so much commotion amongst merchants, shipowners, and speculators, and which has given rise to the employment of many vessels from some of the principal ports both of England and Scotland, in this new branch of trade, is situated in 26° 18′ 34″ south latitude, a few miles (about twenty-two) north of Angra Pequina—a well determined position, which vessels bound for Ichaboe generally try to make. The main land, for several hundred miles on both sides of Angra Pequina, presents to the eye of the mariner a barren, inhospitable, and dangerous line of seacoast, lying low, though backed with high land in the interior. The strong glare arising from the arid sand and the density of the atmosphere calls for the utmost vigilance and caution on the part of the master-mariner approaching it during the night; for, if he once gets deceived, and into the current which sets upon the shore, the destruction of his vessel is inevitable. Along this line of coast there is not the slightest symptom of vegetation; indeed, it is much to be questioned whether vegetation would thrive, whatever might be the quality of the soil, as no rain falls in this region. True, there are heavy dews, occasionally falling both day and night; but the cold is so severe, for such a high latitude, during the fogs, and the sun, when it does break forth, is so powerful and scorching, that, in all probability, between these alternating temperatures and opposite extremes of weather, no vegetation could survive. The island itself is a barren, shelving rock, about a mile long from north to south, and half a mile across at its broadest part,—viz., from its south-west to its north-east point. It is bounded all round by reefs, except on its eastern side, where there is anchorage in from five to six fathoms. A portion of the island is in the form of a flat shelf, about 1100 feet long and 500 feet broad in the widest part. Upon this shelf is accumulated that deposit of guano which gives so much celebrity to the island, and which varies in depth from 35 to 36 feet. Taking the average width of the deposit at 400 feet, and assuming the average depth to be 36 feet, the total quantity of guano will be about 158 millions of cubic feet. The climate of Ichaboe, notwithstanding the effluvia of the volatile ammoniacal gases emitted from the guano, is very healthy. As one proof of its salubrity, he mentions the fact, that at a period when no fewer than thirty-five ships were lying off the island, their crews, comprising altogether not fewer than about seven hundred men, most of whom were enduring exceedingly laborious employment in that hot region, there were only five cases of sickness within his knowledge, and these were complaints or affections of the lungs. As has been already remarked, there falls during the night a very heavy dew, attended with a piercing coldness of temperature; and even during the day, if the sun's rays be intercepted, a cold disagreeable sensation was immediately experienced. On the sun again breaking forth, its rays speedily scorched the lips, and indeed the whole face and hands of every person of fair complexion; and the lips of very few escaped this tormenting annoyance. Our informant suffered the most excruciating pain in his lips, and the skin of his face and hands, from which the only relief he could find was by anointing the skin with hog's lard, in imitation of the custom of the inhabitants of the mainland, who profusely lubricate their persons with palm oil. With reference to the guano itself, the notes to which we refer express a decided opinion on the part of the writer, that the substance is not, as has been generally supposed, exclusively composed of the excrement of marine birds, which he believes to form only a comparatively small portion of the mass. He supposes it chiefly to consist of the decomposed bodies of marine birds and animals, together with the eggs of the former and the excrementitious matter of both. Amongst other facts and grounds for his adopting this opinion, he mentions the following:—He personally superintended the working or excavating of a pit of guano, 35 feet by 18 feet, and from all that came daily under his observation, he was inclined to the opinion that this barren rock had been a favourite placed of resort for ages, for penguins and other aquatic birds: that myriads of them had successively deposited their eggs there, and had subsequently died on the island; and that it had also been a favourite haunt of seals and other marine animals. In working the pit the men occasionally came to a stratum of a light brown colour, and of greater levity than the strata above and below it, and embedded in this stratum they invariably found numerous skeletons of penguins, in the last stage of decomposition, and vast quantities of their eggs. Having worked through this, the men would, probably some after a time to another stratum of a much darker brown, and much heavier description; and the substances composing the bulk of this stratum, when rubbed between the fingers, would dissolve like tallow and exude much more oil or fat than the first. Throughout this dark-coloured stratum, the men occasionally found many bones and skeletons of seals nearly decomposed, and but very rarely any remains of penguins. The appearance of the stratum suggested to him the idea of a great number of seals having been washed on shore, or having laid down in this spot to die. He adds that the strata were not by any means regular in their alternations; but as a general rule, he did not find both the light and the dark-coloured strata in close succession. The pitshere referred to was in the centre of the island.—*Manchester Guardian.*

Notices to Correspondents.

BARKING TREES.—*Clericus V.* asks if any of our correspondents can suggest a simple means of preventing cows from gnawing the bark of trees?

CHARCOAL.—*E. Bate*—This word applies only to charred *wood*. Charred coal is *coke*

CLOVER SEED, &c.—*A Beginner.*—Italian Rye grass is the best substitute now. Sow gypsum broadcast in wet weather, early in spring. Soap-ashes and gypsum are both useful additions to your compost heap; the more compound you can make it the better. If you put burnt gypsum into your tank put in but little at a time, and stir it well, and it will not cake. Sulphuric acid is, however, a better material; on this, however, we must refer you to articles on liquid manure and fixation of ammonia in the two last Numbers of this Paper. You must not add lime to any manure containing ammonia, or producing it, during putrefaction. The two substances are incompatible, and lime is the stronger of the two, so that it drives off ammonia wherever it meets with it. Fresh mould and freshly-burnt charcoal powder are both good things to mix with cloacine, whether the object be to check smell or loss of ammonia.

DISEASE IN PIGS.—*Anon., Holly Bank*—Next week.

DRAIN-TILES AND CHEMICAL APPARATUS.—*Agricola.*—The notice by Mr. Cottam of the Benenden tile-machine, in our last week's report of the weekly meeting of the English Agricultural Society will perhaps serve your purpose. With regard to your second question we answer, "the former."

ELECTRO TINNING.—*M. Q.*—We have made fruitless inquiries on this subject. Probably the expense would be an insurmountable objection. Will the ordinary earthenware pans, or the glass ones now coming into use, not answer your purpose?

FAILURE IN CLOVER.—*E. T.*—You must wait till after harvest, and sow Italian Rye grass, and, if the land be in suitable condition, Clover seed on the patches, which, if the weather be favourable, will soon be covered.

FLAX DODDER.—*H. F.* informs us that a field of Flax which he lately visited is being rapidly destroyed by this weed, the appearance of which there cannot be accounted for, as the seed was grown by the occupier last year, and there was no Dodder amongst it. We must suppose that his informant has been mistaken on this point. The only way to get rid of it is to use clean seed on clean ground, and that is necessarily effectual. The Clover Dodder at first is nourished from the ground, but as soon as it has laid hold of its victim, it becomes wholly parasitical. (See p. 697 of *Gard. Chron.*, 1843.)

FLOUR MILL.—*W. C.*—We have no experience. Dean's bears a high character.

GRASS SEEDS.—*Delta* says that "Arthur Young said that he had sown Grass seeds in August and September, and never failed, but on sowing them in spring he had often failed. In all modern works these seeds are recommended to be put in at spring time. Have Arthur Young's opinions lost their former worth? or is modern experience better than his? Yet even now-a-days his principles of farming are inculcated as the true ones; but his name is seldom uttered." It is, we believe, *sufficiently* well established that Clover and Grass seeds are surer of successful growth if sown in spring than if sown in autumn. 4 lbs. of burnt gypsum are equal in chemical effect to about 8 lbs. of the mineral. Only, if you use the former on land, take care to spread it evenly, for if any quantity together get wetted, it will *set*, and be almost useless.

LAND SOCIETY.—*H. F.*—We do not know Mr. F. O'Connor's work. It appears to us that the purchase of land to be cultivated by the spade is a very *expensive* mode of patronising spade culture.

MANGOLD WURZEL.—*Silton*—It is good food for sheep. It improves by keeping, and should not be used till April. We grew 600 tons last year, of which 400 must have been eaten by sheep.

POTATO WASHER.—*W. C.*—The Potato-washer that we use is a cylindrical framework 20 inches in diameter and 40 inches long, whose axle works in Ys, placed about three inches above the level of water, in a box. From this box, on one side of it, two curved arms extend; and when the Potatoes have been thoroughly washed, the chains attached to the extremities of these arms are hooked into eyes on the axle of the cylindrical framework, so that on continuing the rotatory movement it is wound up out of the water with its contents, which are thus easily removed.

SULPHURIC ACID.—*A Wiltshire Clergyman.*—It should be diluted with five or six weights of water, when used on the dunghill, and with two or three weights when to be used in the tank. Jerusalem Artichokes are not poisonous when given to pigs or young cattle along with other food; that is the amount of our experience. Thanks for your hint about referring to back Numbers.

ERRATUM.—Page 466, under the heading "Drainage," for "Charcoal is almost impenetrable," read "Charcoal is almost imperishable."

***As usual, many communications have been received too late.

Southdown Fleeces	11d 1 0		

JAMES FRASER, Wool Broker.

COVENT GARDEN, JULY 20.—The market has this week been well supplied with both Fruit and Vegetables, and the latter are of better quality than they were last week. Trade has also been a little quicker. The Apples were good and plentiful. A large quantity have been imported from Hamburgh and Mexan, in the Baltonni Islands. They are of the Ribbed Rye and Providence varieties, and are offered at from 2s. to 3s. 6d each. They arrived in good condition, but are said to be of rather inferior quality. In the Bahama Islands they have a very large staple pine-apple, and arrangements have been made for a particular supply from those Islands; three or four shipments are expected during the present season. Of Pumkins and Marrows there is a good supply, and Grapes, Cherries, and Plums, are sufficient for the demand. Gooseberries, Currants, and Strawberries, are also plentiful; some fine Melons are also in the market. Among Vegetables, Cauliflowers are getting scarce and have considerably advanced in price since our last report. Cabbages are a little cheaper, as are also French Beans. Peas are plentiful at last week's prices. Little attempt has been taken place in the prices of Carrots or Turnips. Potatoes are a little dearer, as is also Celery. Vegetable Marrow is nearly the same as it was last week. Among Cut Flowers we noticed several species of Erica, Erythrina, Cistus galli, Ceanothus azureus, Carnations and Picotees, Verbenas, Pelargoniums, Gardenias, Fuchsias, Moss, Provence and China Roses.

FRUITS.

Pine Apple, per lb., 4s to 8s		Gooseberries, per bf.-sieve, 1s 6d to 2s

Savory, per bunch, 2d to 4d		Marjoram, per bunch, 4d to 6d	
Cucumbers, each, 2d to 1s 6d		Chervil, per punnet, 2d to 3d	

MARK-LANE, MONDAY, July 15.

We had a good supply of English Wheat at Market this morning, which met a slow sale at a decline of 1s. to 2s. per qr., at which reduction a large proportion remained unsold. For Foreign there was a retail inquiry; the finest old at about late prices, but common descriptions and new must be written fully 1s. lower.—Barley was very dull, but we do not alter our quotations.—Beans are again 1s. cheaper, and Peas are the turn lower.—The arrival of Oats being very considerable, little progress could be made with sales, even at 1s. below the rates of last week.

FRIDAY, July 19.

The arrivals of Wheat during the week have been good; the trade, both for English and Foreign, very dull at Monday's quotations, business being extremely limited, and confined to necessitous purchasers.—Barley is a heavy sale.—We observe no alteration in Beans and Peas.—Oats continue difficult of disposal, but there appears less inclination to press sales than there has been.

KINGSFORD AND LAY.

HOPS, FRIDAY, July 19.

Since last week the accounts continue to come more unfavourable; the duty, in consequence, is receding, and the market improving.

PATTENDEN & SMITH, Hop-Factors.

SMITHFIELD, MONDAY, July 15.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 8 to 4s 0	Best Downs & Half-breds	3s 10 to 4s 2
Best Short Horns	3 6 3 8	Best Long-wools	3 6 3 10
Second quality Beasts	3 0 3 4	Ewes and second quality	3 2 3 6
Calves	3 8 4 4	Lambs	4 4 5 0
Pigs	3 4 4 0		

Beasts, 2004; Sheep and Lambs, 24,260; Calves, 164; Pigs, 260.

Although we are not over-supplied with good Beasts, the trade is heavy; the best Scots, &c. find, however, plenty of buyers at, and in some few instances a little over, 4s per 8 lbs; there is a tolerably ready sale, too, for best Short-horns at 3s 8d; but we have a large proportion of middling quality which are not readily disposed of. Very few remain unsold. We have a full market of Sheep, and trade rules rather heavy; notwithstanding, very nearly all are sold, there being a great many bought for keeping. Our top quotations were tolerably well supported in the most middling Sheep of each description, but Ewes were very heavy on hand, there being so much choice of good Sheep. The best Lamb is rather a brisker trade, but we have a large supply of very middling quality which are very unselling. Calves is a pretty good demand for the best Calves at fully 4s 4d per 8 lbs.

FRIDAY, July 19.

Our supply of Beasts to-day is moderate; we cannot observe any alteration from Monday's prices; the best Scots, &c., are making about 4s, and the best Short-horns about 3s 8d per 8 lbs. Our supply of Sheep is rather short-in-deed, and the best qualities are readily sold at Monday's quotations. Good Lamb is rather scarce, and fully maintains its price, 5s per 8 lbs; we have much very inferior making no more than about 4s 4d. The demand for good Calves is rather brisker, and there is a small advance in the best qualities, they making 4s 6d per 8 lbs.

Beasts, 807; Sheep and Lambs, 9660; Calves, 220; Pigs, 340.

MANURES.—The Readers of the Gazette, who must have noticed the considerable quantity made there of the Adulterations of Manures, that are also carried on to a fearful extent,

The Advertiser, a Chymist of the City of London, and in daily communication with several scientific gentlemen connected with the cultivation of the Nobility, Agriculturists, and Gentry, on the question of supplying Manures, by which a genuine article is ensured. Each article is Analysed; and the analysis forwarded to the purchaser, who can by this means obtain redress against the article differ from the analysis.

Terms, Cash and one per cent. commission for charging and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought to the market.

Price current, London, June 12, 1844:—

Bones . . p. ton, £4 10s. to £5		Nitrate or Potash . . £21 0s. to £21 10s.

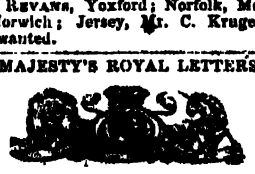
WM. NORTHCOTE, 18, Rood-lane, Fenchurch-street.

TURNIP SOWING. — BRAIN'S ENGLISH GUANO MANURE.—This powerful Manure having been subjected to the most rigorous Analysis by some of the first Agricultural Chemists of the day, it is pronounced by them to be much stronger, and to possess more highly fertilising properties, than the very best samples of foreign brought to this country. Price 9l. per ton; no charge for sacks, and delivered free of charge to any wharf, railway, or waggon-office in town. —Address, FREDERICK BRAIN, Guano Works, Thomas-street, Stamford-street, Blackfriars-road, London.

N.B.—Directions for use sent with all orders.



TURNIPS, &c.

DR. HALLETT'S DRY SOLUBLE FERTILISERS are composed of all the useful ingredients of the best Foreign Guano, which manure is already nearly exhausted, and no two parcels of which were ever alike. They contain also other ingredients equally useful, and are always to be produced of uniform strength; they are improvers of all soils, but most so of poor ones, and cannot possibly prove injurious to soil or crop, as they contain no heating or caustic materials, being simply and purely Fertilisers. Five cwt. of either of them is equal to nearly 30 tons of horse-manure as a Fertiliser. They are used, the one for all the varieties of Corn, Peas, Beans, Chicory, &c., and the other for Turnips, Mangold Wurzel, Natural and Artificial Grasses, and all Gardening purposes. This is the best protector yet discovered against the Fly in Turnips, for it gives a first growth three weeks beyond that of any other known Manure. Price of each Fertiliser, 10l. per ton, or 12s. per cwt.

Sold by Mr. FOTHERGILL, 40, Upper Thames-street; and Mr. G. HALLETT, at the Factory, Broadwall, Blackfriars, London. The Fertilisers are manufactured under the immediate inspection of J. J. HALLETT, M.D., &c.

Agents for London, Messrs. WINSTANLEY, Chemists, 7, Poultry; Suffolk, Mr. W. REVANS, Yoxford; Norfolk, Messrs. BULLARD and WATTS, Norwich; Jersey, Mr. C. Kruger. Respectable country agents wanted.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

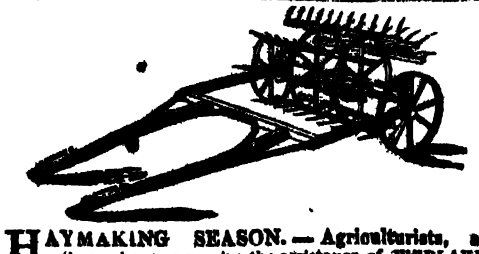
PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade. THOS. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

IMPORTANT to AGRICULTURISTS.—ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), with the view of ascertaining whether the soil on which it is proposed to grow any particular crop contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general.

Gentlemen Instructed in Agricultural Chemistry; the Course will comprehend the Elements of Analysis.

No. 5A, Hawley-road, Kentish Town.



LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also, those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for hire, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset-street, Fleet-street, London

WRIGHT'S STACK PRESERVER.—Hundreds of Stacks of fine Hay were saved from spontaneous combustion or discoloration in the neighbourhood of the inventor, by the use of the above invaluable instrument. The article may be seen, and bills obtained, containing testimonials to its value from experienced Farmers who have for many years proved its efficacy, at J. WRIGHT'S, Manufacturer, Ongar, Essex; J. and G. DRANE, Ironmongers, London-bridge; and of any Ironmonger in the country. Price, in box, with lock and joints, 2l. 5s.

HAYMAKING SEASON. — Agriculturists, and all others who may require the assistance of WEDLAKE'S PATENT DOUBLE-ACTION HAYMAKING MACHINE, are requested to send their orders early to the London Depôt, No. 118, Fenchurch-street, opposite Mark-lane, where one of the Machines may be inspected.—Catalogues of Agricultural Implements and Machinery may be had on application.

FLOWER AND PLANT MANURE.

HUMPHREYS'S SOLUBLE COMPOUND.—A few grains occasionally dissolved in the water in which Plants produce a vigorous growth and splendid flowers. It will be called "*Liquid Guano*" as desired, a superior article for extract by dissolving half a bottle of this powder in a gallon of water and using a table-spoonful to a gallon in watering flower-pots. *Sold in bottles, 1s. 6d. each*, by Chemists and Seedsmen. DAVY, MARTIN, and Co., 180, Upper Thames-street, London.

N.B. In these days of *deception*, it is due to those persons who send out a really good article, that those who benefit by it should make it known."—See Evidence of J. T. Pearson, Chiltern Nurseries, *Chronicle*, p. 292, "*Humphreys's Compound.*"

YORKSHIRE LAND-DRAINING ASSOCIATION.—At a MEETING of the PROVISIONAL COMMITTEE held at YORK, this day, for the purpose of Allotting the Shares applied for in the Association, and on other business—

It was resolved that the number of Shares now allotted being amply sufficient to justify the Committee in proceeding forth with to carry out the objects of the Association, the necessary Deed of Settlement be prepared for execution. And that such of the Public as may yet be desirous of becoming Shareholders, and shall signify the same to the Solicitors (Messrs. BLANCHARD, RICHARDSON, and GURCH, York), or to the Secretary, (Mr. CHARNOCK, Wakefield), on or before the 31st of July next, shall be admitted if the number of unallotted Shares be sufficient), on the same terms as the present Subscribers.

York, June 12, 1844. JAMES HAMERTON, Chairman.

FARMERS' and GRAZIERS' MUTUAL CATTLE INSURANCE ASSOCIATION. Offices, 366, Strand, London.

The especial object of this Association is to give to Farmers, Graziers, and Owners of Cattle the best means of protecting themselves against losses by those diseases and accidents which they can neither foresee nor control, but which have hitherto been most injurious, and often ruinous to thousands.

To prevent fraud, no owner will receive in any case more than two-thirds of the *bonâ fide* value of the animal lost, but he will be entitled to one-third of the value of the skin and carcass.

Insurances may be effected in two ways.

1st. The Owner may have his stock valued by the Inspector of the Association, and pay upon the full amount, and receive two-thirds of the market value of the animal dying (*i. e.*, the value of it the day before the disease manifested itself). For example:—If the full value of the stock, allowing for the improving condition of the animals during the coming year of insurance (for their increasing value during that period must be calculated), amounts, or will amount, to 1000*l.*; then, the premium on 1000*l* being paid, if any one or more die, two-thirds of their market value will be paid, be they worth what they may.

2d. If the owner elects making his own estimate and average, he will receive two-thirds of the said value of the animal dying, provided such value be not more than the average he has specified; and when of smaller value, two thirds of such smaller value only, the Directors having power to grant additional compensation, should they see fit. For instance:—If the stock consists of 100 head, and the average fixed be 10*l.*, then the premium to be paid will be upon 1000*l.*; and if one or more die, of the value of 10*l* (to be certified by the Inspector), the owner will be paid two-thirds of his average (less two-thirds of the skin, &c.); if worth only 8*l.*, then two-thirds of 8*l.*, &c.; but if the animal were worth 20*l.*, he will receive only two-thirds of his average (10*l.*)

PREMIUMS.

Neat Cattle and Cows, against death by all diseases and accidents save *pleuro pneumonia* (usually called the "Epidemic") 30*s.* per 100*l.* value.

Including *pleuro pneumonia*, 20*s.* per cent. additional; being at the rate of 50*s.* per 100*l.* alue. *Pleuro pneumonia* will not be taken alone at this latter rate.

Prospectuses and every information may be obtained at the Office, if by letters, post paid, addressed to WILLIAM SHAW, Esq., 366, Strand, London; or the Agents in the country.

HENRY FLOWER, Secretary.

AGRICULTURAL COLLEGE.—A PUBLIC MEETING will be held at Southampton on Wednesday, the 24th instant, at one o'clock, which will be attended by a Deputation of the Committee of Management and others, who are now engaged in the establishment of a College on a Farm, for giving a scientific and practical education adapted to Agricultural pursuits. At this Meeting, the object of the Institution will be fully explained, also the mode of carrying it into effect. The attendance of all interested in the important object is particularly requested.

PHILIP PUSEY, Esq., M.P. has consented to take the Chair.

By Direction of the Committee. ROBT. J. BROWN,
Cirencester, July 18th, 1844. Hon. Sec.

ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

GREAT NATIONAL CATTLE SHOW OF IRELAND.

THE SOCIETY'S THIRD GREAT AGRICULTURAL MEETING, and Exhibition of Breeding and Fat Stock, Horses, Sheep, Swine, Flax, Wool, Butter, and Agricultural Implements, &c., open for General Competition, will take place on Wednesday and Thursday, the 14th and 15th days of August next, at the COBOURG GARDENS, Harcourt street, in the City of Dublin.

Wednesday, the 1st of August, will be the last day for serving Notices of entry for Stock, &c., and Premium Sheets, and Blank Forms of Entry can be had, on application to the Secretary, at the Society's Rooms, 37, Upper Sackville-street, by whom they will be forwarded.

All Persons desirous of exhibiting Farming and Agricultural Implements are requested to send in Lists and Descriptions of the different articles to the Secretary, on or before the 1st of August, in order that they might be published in full in the Catalogue.

THE FIRST OR COUNCIL DINNER will take place in the Round Room of the Rotunda, on Wednesday, the First Day of the Show, when the Marquess of Downshire, Chairman of the Council, will preside.

THE GRAND BANQUET will be held on Thursday, the 15th of August, in the Theatre Royal, Hawkins's-street, on which occasion His Grace the Duke of Leinster, President of the Society, supported by the different Noblemen, Vice-Presidents, and Members of the Council, will fill the Chair. The Dress Boxes will be appropriated exclusively to Ladies.

The Premiums to be distributed on this occasion will amount to upwards of ONE THOUSAND POUNDS, and every facility will be given to the Exhibitors of Stock and Implements.

The AGRICULTURAL CHALLENGE CUP, Value ONE HUNDRED SOVEREIGNS, and now held by Geo. A. Grey, Esq., by his Short Horned Bull, Recruit, will be also challenged at the Meeting.

There will be an Auction of Stock in the Show Yard after the Show.

Places at the different entertainments will be specially reserved for strangers attending the Meeting.

The Society's Annual Report for 1843, and first part of its Transactions, are now ready for distribution, and may be obtained by members free, or by non-subscribers at One Shilling a Number, on application to Messrs. Curry and Co., Dublin; Fraser, Edinburgh; and Longman, London, the Society's publishers, who are making the necessary arrangements for its circulation all through the Kingdom. By Order, EDWARD BULLEN, Secretary.

Society's Rooms, 37, Upper Sackville-street, Dublin.

KEENE'S PATENT MARBLE CEMENT.—This CEMENT is particularly adapted for the Walls and Floors of Cellars, Vaults and Underbuildings, being calculated, from its extreme hardness, to resist the wear incidental to ordinary Pavements. For Floors it has a threefold advantage over Stone paving, &c. in its cheapness; one inch in thickness of KEENE'S CEMENT answering where 2 to 3 inch flagging would be employed. Next, in its superior durability, resisting as it does, the dampness of stone with its joints and cross-barring from frost joints; and lastly, in economy being one-third the price of flagging.

The most satisfactory evidence can be given of the utility of KEENE'S CEMENT for the purposes for which the Patentees and Manufacturers recommend it, by applying to Messrs. Blank-street, Westminster.

EXTIRPATION OF BUGS & VERMIN.—OLD, by appointment, to Her Majesty the Queen, H.R.H. the Prince Consort, and the Duchess of Kent, H.R.H. the Duke of Cambridge, the Royal Agricultural Society of England, and the Corporation of the city of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, and country agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to three years, every description of PROPERTY of rats, mice, moles, wasps, moths, fleas, bugs, &c., and is authorised by the quality of his preparation respectfully refers to the certificates of the great numbers of Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Marlboro' House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Dudley Quays and warehouses in Upper Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5s., 10s., 20s., and 100s. each, with full directions, which must be used in proportion to the extent of premises infected to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling-houses cleansed from 1l. to 5l. per annum; mansions and estates from 10l. and upwards; ships, docks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal Joseph Anton Meyer.

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of searching thoroughly into the divisions of the teeth, and cleansing them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose. 1s. An improved Clothes' Brush, that cleanses in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and effectual manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the first duty of a genuine Smyrna Sponge. Only at METCALFE'S Establishment, 180a, Oxford-street, one door from Hollis-street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6, 1844.*—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup; giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 6, 1844.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

SURPRISING EFFICACY of "PARR'S LIFE PILLS."

Testimonial just received by the Hibernia from America.—Dr. C. STEANE, 184, Fulton-street, sole agent for Brooklyn, L.I.—An instance of the singular efficacy of PARR'S LIFE PILLS, which merits particular notice, occurred in the person of a lady, residing at Brooklyn, of consumptive make, who had been afflicted for upwards of six years with very great and general debility, headache, flatulence, faintings, and all the effects originating in an impaired constitution. Country air was tried, but to little advantage. She complained of weariness and pain on the least motion; her bowels were sometimes constipated, and at other times lax, and never regular. At this period, she was recommended to try PARR'S LIFE PILLS, when, no less astonishing than true, before she had finished two boxes, an entire and perfect cure was the result. To such, nothing can equal this antidote, as it imparts tone and strength to the stomach, and operates so mildly, that the most delicate of either sex can take them with the greatest safety.—Yours truly,

To T. Roberts & Co., April, 1844. C. STEANE.

These and hundreds of other cases of decided cures, attested on the highest authority, and already published, occupy upwards of 150 pages of letterpress. These Testimonials are published periodically, and may be had on application at any respectable medicine vendor's. The cures in many instances were effected after all other means had failed, and they thus establish the claims of PARR'S LIFE PILLS in being considered the best medicine in the world.

CAUTION TO THE PUBLIC.—Beware of spurious imitations of the above Medicine. None are genuine unless the words "PARR'S LIFE PILLS" are in WHITE LETTERS on a RED GROUND, engraved in the Government Stamp, pasted round each box; also the fac-simile of the signature of the proprietors, "T. ROBERTS & Co., Crane-court, Fleet-street, London," on the directions.

PRESERVES and CONFECTIONERY. — The superiority of BETTS'S PATENT BRANDY for PRESERVES and CONFECTIONERY, is testified by the fact that it is preferred to any other spirit by the most extensive WHOLESALE CONFECTIONERS in the METROPOLIS; for fortifying Home-made Wines it is invaluable; as an Ordinary Beverage it is congenial to the most delicate constitutions; and, as a Medical Stimulant, it is peculiarly adapted to persons of bilious or dyspeptic habits. Quantities of not less than Two Gallons, supplied at the Distillery, 7, Smithfield Bars, in Stone Jars, at 16s. per Gallon, exclusive of the price of the Jar; and in Glass Bottles, at 20s. per Gallon, Bottles and Case included.

CONSUMERS of BRANDY are respectfully informed, that J. T. BETTS, Jun., and Co., will not be responsible for any BOTTLED BRANDY that is not protected against fraudulent substitution, by the PATENT METALLIC CAPSULES, made of pure and solid metal (*not tin-foil*), embossed with the words "Betts's Patent Brandy, 7, Smithfield Bars," *to which attention is especially directed.*

TO ARTISTS, DRAUGHTSMEN, &c.

PERMANENT DRAWING CRAYONS in Cedar, in Twelve Tints.

WOLFF & SON beg to call the attention of Artists & Amateurs that they have by the introduction of great improvements in their CRETA LAVIS, qualified it to be called like some as the ordinary pencil and effects can now be produced equal to water colour drawings, without the use of water and the inconvenience of the various colours blending together while in use. Its softness, beauty, and richness It can be used to delicate tints, while they are capable of giving a very delicate outline For architectural purposes the great advantages resulting from the use of the CRETA LAVIS must be obvious as without the use of water, pointe brushes &c all the various tints can be obtained with a faithfulness that cannot be surpassed. They are [illegible] every other method in general use.

The Drawings [illegible] in a portfolio with safety as unlike other crayons they will not rub off nor suffer injury by coming in contact with the other contents of a portfolio

The CRETA LAVIS will not be affected by heat or change of climate and by its compact form may be carried any distance without the slightest inconvenience To be had of all respectable Stationers and of the Manufacturers at the following prices —

Leather box, containing a set of 12	..	7s	each
—	—	—	18	10s —
—	—	—	24	14s —
—	—	—	36	.. 21s —
In sets as above, without box, at.....				6s per doz
Lake and Cobalt				12s —

*** May be had also in Crayons without cedar, in sets as above, at 6s per dozen, box included

Creta Lavis —We have inspected an invention of Messrs Wolff & Son Creta Lavis are permanent coloured Crayons, of nearly every hue and tint, differing essentially from those in general use, inasmuch as they do not cast off and are clearer than chalk, retaining at the same time much softness and delicacy We think they would be found useful to the sketcher as they are portable not easily injured, and can be used upon white or tinted paper We can recommend them especially to ladies as we have seldom seen more charming specimens of flower drawing than those produced by the Creta Lavis the blue, generally so coarse in chalk, was singularly clear, and many of the landscapes and heads submitted for our inspection proved that Mr Wolff has made a valuable discovery "—*London Art Union*

Instructions for Use—To prodpce the delicate shades the chalk must be cut to a fine point, and worked very lightly on the paper, blending the colours until the required tint be obtained The deep shades merely require a broader point and increased pressure —Bristol Board, Crayon paper &c, in fact, any papers with a fine even surface not glazed, are well adapted for the CRETA LAVIS; but tinted crayon papers are most suitable, as they add to the finish of the drawing

WOLFF & SON beg to recommend their newly-invented SKETCHING PENCILS or Permanent Black Chalks —

B B, Very Black, for foregrounds; H B, Middle tint, N, Neutral tint for distance Price 6s per dozen.

These Pencils are particularly adapted for sketching heads and landscapes, and are capable of producing a beautiful effect with very little labour Having an [illegible] the drawings may be transmitted without fear of injury.

*** WOLFF & SON are desirous of treating an Agency with respectable Country Booksellers and Stationers for the sale of the above —Manufactory, 24, Charles street, Spitalfields, London.

BURBIDGE AND HEALY'S COOKING APPARATUS combining Sylvester's Patents.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship, in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B & H can safely recommend it from experience, as unquestionably superior to anything of the kind hitherto made A Prospectus can be forwarded, upon application, detailing particulars and prices, to 130, Fleet street

STATE LOAN of His Royal Highness the Grand Duke of Hesse for 4,000,000 fls., to be reimbursed with 2 annuities, in lots of 40,000, 20,000, 10,000, 5,000, 2,000 fls., &c., the smallest being 50 fls —GRAND PUBLIC DISTRIBUTION to take place at Carlsruhe on the 1st of August next, official bulletins containing the result will be forwarded immediately to every shareholder. Price of a single certificate, 10s; 11 for 5l; 23 for 10l; 60 for 25l. sterling; payable in notes money orders, or remittances —Apply for full particulars and certificates, without delay, to Moritz Stiebel, banker Frankfort-on Maine To save postages, all letters addressed to Messrs Stiebel and Co, 8, Lime street, London, will be promptly forwarded and attended to

THE COUNCIL
OF THE
Horticultural Society of London

HAVING ascertained that a very large number of Exhibition Tickets of the present season have not been used, chiefly on account of the unfavourable weather of the 13th—the last day fixed for the Exhibitions; and

HIS GRACE THE DUKE OF DEVONSHIRE,

the President of the Society, having most kindly offered again to throw open the grounds of Chiswick House,

NOTICE IS HEREBY GIVEN

That there will be on WEDNESDAY, the 31st of July, a MUSICAL PROMENADE in the Society's Garden, at which the unused Tickets of the present season will be received. Other Tickets for the occasion will be issued till the 30th inst., at this Office, price 2s. 6d. each, or at the Garden on the 31st inst., at 5s each, under the regulations already in force for governing admission to the Exhibitions at the Garden. The usual refreshments will be supplied by Messrs. Gunter—21, Regent-street.

ARRANGEMENTS TO BE OBSERVED BY THE MILITARY BANDS

IN THE GARDEN OF THE HORTICULTURAL SOCIETY,

July 31, 1844 (weather permitting).

The Bands of the 1st Life Guards, Royal Horse Guards, Coldstreams, Fusiliers, Royal Artillery, and Sappers and Miners, will take their stations in the Society's Garden by 1 o'clock, when the five first will commence playing as usual, and the Sappers and Miners will proceed at once to their position at the Duke of Devonshire's. At 20 minutes to 2 P.M. the Bands in the Society's Garden will march from their several stations to an orchestra prepared for the purpose, where they will play the *Overture to Lampa*. At the conclusion of this piece the Coldstreams and Royal Horse Guards will file off in two divisions into the Grounds of His Grace the Duke of Devonshire. The 1st Life Guards, Artillery, and Fusiliers will remain in the Society's Garden. At half-past 2 o'clock the 1st Life Guards, Fusiliers, and Royal Artillery will move into the Grounds of Chiswick House, where all the Bands will collect and play the *March in Oberon*. After this the Bands will resume their former stations. Shortly after 3 P.M. the Bands in the Duke of Devonshire's Grounds will march back to the Society's Garden in two divisions, and joining the Artillery, Life Guards, and Fusiliers, the whole will again collect in the orchestra. Thus united, the Bands will play the *March Triomphale of Ries*, the *Overture to Fra Diavolo*, and the *Prince of Wales's March*, by Costa, the whole concluding with *God Save the Queen*, as newly arranged by Costa. At the conclusion of these pieces the Bands will quit the Garden. In the intervals between the concerted pieces the Bands will play separately, as usual. In all cases, when the Bands move from place to place, they will march, playing the *British Grenadiers* in E flat.

*** The concerted pieces will be conducted alternately by the Bandmasters of the five principal Bands.

THUNBERGIA CHRYSOPS

WM. SKIRVING, NURSERY AND SEEDSMAN, Walton, near Liverpool, begs to offer the above new and splendid Climber, surpassing in beauty all others of the genus yet introduced. It is a native of Sierra Leone; a perennial of strong and shrubby habit, and a free bloomer. Colour, dazzling purple, with rich yellow eye. Raised at Knowsley Hall, from seed imported by the Right Hon. the Earl of Derby, and presented to W. S. by his lordship. Plants are now ready to be sent out at 10s. 6d. each.

Orders accompanied with a remittance or a respectable reference, will be faithfully and promptly executed.—Walton Nursery, 25th July, 1844.

SHILLING'S QUEEN CABBAGE.—This month and part of August being the time to sow Cabbage Seed for the Autumn and Spring Planting, J. & S. SHILLING having a little Seed left of the above very superior kind, which they highly recommend to those who have not already tried it—beg to offer it to the Public generally, in half oz. packets, postage free, at 2s. 6d. each, on the receipt of postage stamps or a Post-office order.—Northwarsden Nurseries, Oulham, Hants.

GREAT YARMOUTH NURSERY — NORFOLK, 1844.

NURSERYMEN AND FLORISTS TO HER MAJESTY THE QUEEN.

YOUELL AND CO.'s splendid and extensive Collection of CARNATIONS, PICOTEES, and FUCHSIAS is now in Bloom together which they beg to invite the attention of Amateurs and others. Upwards of 3000 pots of Carnations and Picotees will be staged comprising all the leading varieties in cultivation, and embracing several new Flowers of the highest merit raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, to which first-class Prizes have already been awarded.

Steamers from London Bridge and St. Katharine's Wharf every Tuesday and Saturday evenings at 6 o'clock. Coaches from Spread Eagle, Gracechurch street via Eastern Counties Railway every morning and evening at 8 o'clock.

Great Yarmouth Nursery, July 27, 1844.

THE BEST 24 VERBENAS EVER OFFERED, for 21s., or TWELVE for 12s.

GEORGE SMITH begs to offer the following splendid VERBENAS which comprise the choicest varieties of the season they were shown at the Royal Botanic Gardens of London and much admired for their distinct colours and fine form, they also obtained the first prize. Smith's Ariel, Excelsa, Delicata, Striata Parsons Beauty Supreme Atro sanguinea, Celestina, Princess Alice, Miller's Blue Queen Louisa Youell's Brilliant, Monarch Surprise, Elegance White's Wonder Variabilis, Surprise, Modesty, Imperial Orange Perfection, Howardii Variegatus, Poulii, Ingramii, Lucia, Invincible, Van Genth, Hisloperas Ne plus Ultra, Renown, Bonfield's Brewarth Princess Royal.

Tollington Nursery, Hornsey road Islington, near London.

FUCHSIAS

W. MILLER'S Splendid Collection of the above beautiful tribe of Plants are now in full bloom comprising all the new varieties sent out this season, besides a number of seedlings raised in the Providence Nursery, Ramsgate.—Admission Gratis (Sundays excepted). July 24, 1844.

WOODLANDS NURSERY, MARESFIELD, near UCKFIELD SUSSEX.

SUPERB NEW FUCHSIAS PETUNIAS, VERBENAS, &c.

WILLIAM WOOD AND SON have much pleasure in offering the following selection of the above in fine condition for autumnal flowering, strong plants of which are now ready for sending out

FUCHSIAS

	each—s	d		each—s	d
Attractor (Standish)	7	6	King John (Hally)	3	6
Boydii (Hally)	3	6	Madame Vaucell	5	0
Colossus (Standish)	7	6	Model de Rival (Smith)	5	0
Conductor (do.)	5	0	Marginata (Hally)	3	6
Coronet (Smith's)	5	0	Neptune (Smith)	5	0
Expansa (do.)	5	0	Reflexa (do.)	5	0
Fair Helen (Hally)	1	6	Vesta (do.)	5	0
Gigantea (Smith	7	6	Wat Tyler (Hally)	3	6

Also the under named, at 12s per dozen, the selection being left to the purchaser, or one plant of each for 10s.—Alata Bellissima, Britannia, Brockmanii Champion, Gorgeous, Defiance, Fulgens, Enchantress Appel Fromentaux, King, Lancii Majestica (Smith's) Nobilissima, Paragon Pulcherrima Rogersiana, Robusta, Smithii Spectabilis Stanwelliana, Transparens Victory. And as under, when the selection of sorts is left to themselves

12	Extra fine varieties for	9s
25	Do do	18s
50	Do do	9 9

PETUNIAS

	each—s	d		each—s	d
Formosissima (Smith's)	1	6	Lady of the Lake (Smith's)	1	6
Kentish Beauty (do.)	1	0	Magna Purpurea (do.)	1	6
Lady Hope (do.)	1	0	Punctata (Miller's)	1	6

Nine named varieties at 6s per dozen, when the selection of sorts is left to W. W. & Son.

VERBENAS.

	each—s	d		each—s	d
Adonis (Croft)	2	6	Delicata (Smith's)	1	0
Azurea grandiflora (Stewart's)	2	6	Elegans Youell's)	1	6
Array (Smith's)	1	6	Excelsa (Smith's)	2	0
Blue Queen (Miller's)	3	6	Monarch (Youell's)	2	6
Brilliant (Youell's)	1	6	Queen of the Whites (Stewart's)	2	6
Carnea superba (Stewart's)	1	6	Surprise (Youell's)	2	6
Defiance (Girling's)	2	6	Zeuxis (Miller's)	2	6

Also the following fine varieties, at 9s per dozen, the selection being left to the purchaser, or one plant of each for 12s.—Amethystina, Barnsii, Beauty, Bishopii Boule de feu, Bridesmaid, Burleyana Fortune teller, Harlequin, Howardiana, Joan of Arc, Laconii, Minstrel Boy, Renown, Rival King, Speciosa, Tagliani, White Perfection.

W. W. & Son have also on hand an extensive collection of Camellias, Miscellaneous Plants, &c., priced Catalogues of which may be had on application.

*** Agents by appointment for the sale of WHITNEY'S TRANSPARENT COMPOSITION, for covering Greenhouses, Frames, &c. Sold in bottles—pints 2s. 6d., quarts, 4s 6d each, with printed directions for use.

NEW FANCY SEED

WILLIAM CLARK, 25, Bishopsgate-street Within, London, is now sending out SEED just gathered, warranted from the best flowers, and can confidently recommend the same, knowing the kinds collected from. In papers of 2s 6d and 5s. each. Also J. H. Cox, Esq.'s superb PICOTEE SEED, 5s per paper. Very fine Calceolaria from the first flowers, 1s and 2s. per paper. Cineraria, from 12 best varieties, 1s per paper. Geranium, fine mixed, 1s. per paper. May be had, on receipt of a Post office order.

ORCHIDACEOUS PLANTS

LOUIS VAN HOUTTE, HORTICULTURIST TO THE KING begs leave to inform the Trade and Public in general, that the Parts No. 13, 14, 15, and 16, of his General Catalogue, with the prices of the Plants and Seeds ready for sale at his Establishment at Ghent in Belgium, may be obtained on application to Mr. Geo. Rann, Covent, Minories, London. L. V. H. would willingly take Orchideæ in exchange to any amount, on the part proposing such an exchange giving him a correct statement of the price and strength of the Orchideæ.

Note.—All Letters to Belgium must be post paid.

T. AND J. BACKHOUSE, NURSERY & SEEDSMEN, York, beg to offer to the public strong plants of the following new and rare species.—Achimenes picta, 10s 6d; Aristolochia gigas, 10s 6d; Lisianthus nigrescens, (small) 2s. 6d. T. and J. B. have also a good stock of Lisianthus Russellianus, Phlox picta, Van Houttii and bicolor, 1s. 6d each. Achimenes hirsuta 2s 6d, and Pentstemon Murrayana, 2s. 6d.

MESSRS. J. and H. BROWN are now sending out to any part of the kingdom the following very desirable Plants for bedding out, &c.—

Antirrhinia grandiflora, 9s per doz.
Verbenas, 12 best new sorts, 6s per doz
Torenia scabra 6s per doz
Potentia punctata, 9s per doz.
Do., three new seedlings, superior varieties, 1s. each.
Scutellaria splendens, 9s per doz.
Phlox Drummondii, 4s per doz
Lantana crocea speciosa, 9s. per doz.
Duchsias, all the leading varieties, 9s. and 12s. per doz.
Rosa Devoniensis, 12s per doz.
Yellow Chinx Rose } 9s per doz.
White do. do. }
Smith's Yellow Noisette Rose }
Nine new Ruff Roses, "Eliza Sauvage," 18s per doz.
Nine new Yellow Carnations, 3s. per pair
Chrysanthemums, newest and best vars by name, 9s. p. doz.
Bouvardias, four varieties, 6s per doz
(The above plants can be sent Post-free)
Nine blooming plants of Achimenes grandiflora, longiflora, picturata roses, and hirsuta, 6s and 9s. per doz.
Genista retrorsa and elongata, 1s each
Do tubiflora, fine new white, 2s 6d each.
Cape Jasmines, 12s and 18s per doz
Nine plants of Double White and other new sorts of Camellias, well set for bloom, 21s per doz
Fine Cineraria Calceolaria, and choice Geranium Seed, 1s 6d per packet.—Albion Nursery, Stoke Newington.

NEW SEEDS

J. G. WAITE, SEEDSMAN, &c., 1 and 4, Eyre-street-hill Hatton Garden, London, in expressing the pleasure he derived (during his late journey) from the praises bestowed on the Seeds he had sent out during the past season, begs to return thanks for the very liberal support he has had from the Country Trade, and to inform them that he has just received the undermentioned NEW SEEDS from his Growers, the whole of which he can warrant genuine, being from his own transplanted stocks.—

NEW THUNBERGIAS—ALATA SUPERBA AND AURANTIACA SUPERBA

JOSEPH TRYER begs respectfully to call attention to his Advertisements in the two last weeks' Chronicles relating to the above two new and beautiful varieties of Thunbergias, &c., which he will begin sending out on the 1st of August (they may be seen in bloom at the Nursery, or blooms will be forwarded on application containing 6 postage stamps).

*** Agent for Potter's Guano, Humphreys's Compound, and Whitney's Transparent Composition.

Clarendon Nursery, Camberwell, London, July 26, 1844.

MAGICAL EFFECT ON FLOWERS.—*Gardeners' Chronicle*, April 27th.—"I cannot speak of POTTER'S LIQUID GUANO in adequate terms of praise. I tried it on Hyacinths and other flowers. The effect was magical. My flowers were the finest I ever beheld, and they preserved their beauty nearly double their usual time."—*W. Aird, Hammersmith.*

"I write to describe the wonderful efficacy of POTTER'S LIQUID GUANO. Peas, Onions, and Asparagus have been singularly improved by it. People come to admire the appearance of the garden."—See *Chronicle*, p. 406.

*** Beware of an ineffectious imitation. See *Chronicle*, p. 405.—"Humphreys's Compound."

Sold by most Chemists and Seedsmen.

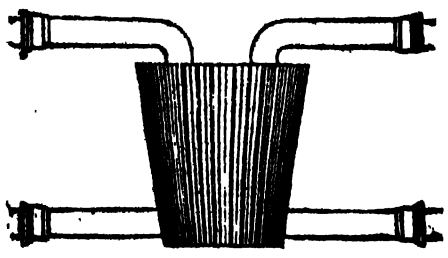
Factory, 20, Upper Fore-street, Lambeth.

LYNDON'S PATENT SPADE.—Sold by GREEN and CONSTABLE, Ironmongers, 20, King William st., London-bridge. Horticultural Tool Chests. Bright Ladies' Spades, Money's Patent Water Pots, Lord Vernon's Patent Hoes, with a general assortment of Garden Implements.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, &c., BOLTON.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 93, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.



D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 190, FLEET STREET, LONDON.

BURBIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURBIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to MR. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.	Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit. Length by feet.
in. ft. s.	s.	s. d.	s. d	s. d.		
10 1 5 Ribbed Boiler.	20	7 6	6 6	2 6	30 feet.	12 to 20
10 2 3	20	10 6	7 6	2 6	50 to 70 ft. 4 in.	Under 25 to 40
12 2 15	30	12 6	7 6	3 6	80 to 125 feet.	40 to 65
14 3 10	35	17 5	8 6	4 6	150 to 250 feet.	65 to 100
18 5 5	42	25 0	8 6	5 6	300 to 400 feet.	Warm a grapery 25ft. long, and a pit 50ft.
24 8 15	50	35 0	8 6	7 6	600 to 800 feet.	

If 3-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

GUANO (GENUINE PERUVIAN & BOLIVIAN)
ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, July 26, 1844.

TURNIP SEASON.

GUANO (Foreign and Potter's), RAPE-DUST, BONE-DUST, CLARKE'S COMPOST, and all other MANURES for the TURNIP CROP, to be had on the best terms, of MARK FOTHERGILL, 60, Upper Thames-street.

GUANO.—Having been appointed agents for some of the largest importers, we will be happy to treat with Merchants or Consumers, for delivery at any Port or Inland Town in the kingdom, at such seasons of the year as may be desired. Orders from houses for the Continent will also receive prompt attention, and every facility for delivery. As we sell cargoes direct from the place of loading, an unadulterated article, in either large or small quantities, may be relied on—a matter of the greatest importance to country dealers, whose interest is to secure the farmer's confidence. Commissioned agents: G. HEARING, BUNNEY, & Co., 67, Cornhill, London; G. and A. HEARING, South John-street, Liverpool.

GUANO.—For Sale, in bags of 1 cwt. each; just landed, with a succession of cargoes to arrive.

There being considerable variety in the qualities of Guano imported from different places, and indeed from the same island, each parcel will be chemically analysed with the utmost precision, to show its relative productive power. A copy of such analysis will be given to buyers, and also instructions as to the most approved mode of using the Guano, furnished by the experience of eminent Agriculturists in England and Scotland.

Large parcels will be delivered direct from the Ship, or waterside premises. Smaller quantities may be had at the warehouses, 24 and 25, Billiter-street; or delivered within any reasonable distance, at a trifling additional cost.—Apply to JAMES CLARK, 24, Billiter-street.

TURNIP SOWING.—BRAIN'S ENGLISH GUANO MANURE.—This powerful Manure having been subjected to the most rigorous Analysis by some of the first Agricultural Chemists of the day, it is pronounced by them to be much stronger, and to possess more highly fertilising properties, than the very best samples of foreign brought to this country. Price 9l. per ton; no charge for sacks, and delivered free of charge to any wharf, railway, or waggon-office in town.—Address, FREDERICK BRAIN, Guano Works, Thomas-street, Stamford-street, Blackfriars-road, London.

N.B.—Directions for use sent with all orders.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, June 12, 1844:—

Bones	p. ton	£4 10s. 0d	Nitrate of Potash	„	£1 4s. 6d
„ crushed	5l. 10s. to 6	0 0	Oil of Vitriol, or Sulph. acid	„	p. lb. 0 0 1
„ calcined		7 0 0	Rape Cake		p. ton 4 15 0
Carbonate of ammonia		p. cwt. 2 16 0	Salts, Epsom	„	9 0 0
Guano, Peruvian, p. ton		11 0 0	„ Glauber	„	7 0 0
„ Ichaboe	„	9 0 0	Sulphate of Ammonia, per cwt., 16s. to		0 17 0
Gypsum	„	2 0 0			
Nitrate of Soda, p. cwt.		0 14 0			

WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street.

IMPORTANT to AGRICULTURISTS.—ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), with the view of ascertaining whether the soil on which it is proposed to grow any particular crop contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general.

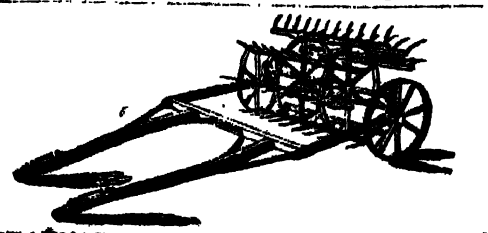
Gentlemen Instructed in Agricultural Chemistry; the Course will comprehend the Elements of Analysis.

No. 5A, Hawley-road, Kentish Town.

TURNIPS, &c.

DR. HALLETT'S DRY SOLUBLE FERTILISERS are composed of all the useful ingredients of the best Foreign Guano, which manure is already nearly exhausted, and no two parcels of which were ever alike. They contain also other ingredients equally useful, and are always to be produced of uniform strength; they are improvers of all soils, but most so of poor ones, and cannot possibly prove injurious to soil or crop, as they contain no heating or caustic materials, being simply and purely Fertilisers. Five cwt. of either of them is equal to nearly 30 tons of horse-manure as a Fertiliser. They are used, the one for all the varieties of Corn, Peas, Beans, Chicory, &c., and the other for Turnips, Mangold Wurzel, Natural and Artificial Grasses, and all Gardening purposes. This is the best protector yet discovered against the Fly in Turnips, for it gives a first growth three weeks beyond that of any other known Manure. Price of each Fertiliser, 10l. per ton, or 12s. per cwt.

Sold by Mr. FOTHERGILL, 40, Upper Thames-street; and Mr. G. HALLETT, at the Factory, Broadwall, Blackfriars, London. The Fertilisers are manufactured under the immediate inspection of J. J. HALLETT, M.D., &c.



Agents for London, Messrs. WINSTANLEY, Chemists, 7, Poultry; Suffolk, Mr. W. REVANS, Yoxford; Norfolk, Messrs. BULLARD and WATTS, Norwich; Jersey, Mr. C. Kruger. Respectable country agents wanted.

TANNER'S VITREOUS FLUID and CLOTH, a Substitute for Glass for Horticultural Purposes.—The Vitreous Cloth proves its superiority over Glass, by producing the light most suitable to vegetation, superseding the necessity of any shading, preserving a healthy moisture on the plant, retaining its bloom to a more lengthened period, less expensive, and not requiring so much attention. The above (retaining heat) is preferable to Glass for Hothouses, &c., the temperature of which is maintained with less fuel. It is equally applicable as a covering for Fruit-trees, preserving them from frost, blight, and excessive heat. The Vitreous Cloth, made by machinery, is much superior to any prepared in a different manner. By the use of the Vitreous fluid, the Cloth (after lengthened service) may be renewed.

The Fluid sold in bottles 2s. 6d. and 4s. 6d. The Cloth 2s. 6d. and 3s. per yard. Manufactured by N. W. TANNER, Chemist, Exeter. Agents for Exeter and vicinity, Messrs. LUCOMBE, PINCE & Co., Exeter Nursery.

To Mr. N. W. Tanner—Sir, we have used your prepared Cloth, and have pleasure in informing you that whilst the light admitted through it is very suitable to vegetation, there has been no necessity to have recourse to any extra shading during the very clear, bright weather which we have so long experienced; this we consider an important point. Yours, &c.
(Signed) LUCOMBE, PINCE, & Co., Exeter Nursery.
June 21, 1844.

*** Respectable Agents required.

HAYMAKING SEASON.—Agriculturists, and others who may require the assistance of WEDLAKE'S PATENT DOUBLE-ACTION HAYMAKING MACHINE, are requested to send their orders early to the London Depôt, No. 116, Fenchurch-street, opposite Mark-lane, where one of the Machines may be inspected.—Catalogues of Agricultural Implements and Machinery may be had on application.

ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

GREAT NATIONAL CATTLE SHOW OF IRELAND.

THE SOCIETY'S THIRD GREAT AGRICULTURAL MEETING and Exhibition of Breeding and Fat Stock, Horses, Sheep, Swine, Flax, Wool, Butter, and Agricultural Implements, &c., open for General Competition, will take place on Wednesday and Thursday, the 14th and 15th days of August next, at the COBOURG GARDENS, Harcourt street, in the City of Dublin.

Wednesday, the 1st of August, will be the last day for serving Notices of entry for Stock, &c., and Premium Sheets, and Blank Forms of Entry can be had, on application to the Secretary, at the Society's Rooms, 37, Upper Sackville-street, by whom they will be forwarded.

All Persons desirous of exhibiting Farming and Agricultural Implements are requested to send in Lists and Descriptions of the different articles to the Secretary, on or before the 1st of August, in order that they might be published in full in the Catalogue.

THE FIRST OR COUNCIL DINNER will take place in the Round Room of the Rotunda, on Wednesday, the First Day of the Show, when the Marquess of Downshire, Chairman of the Council, will preside.

THE GRAND BANQUET will be held on Thursday, the 15th of August, in the Theatre Royal, Hawkins's-street, on which occasion His Grace the Duke of Leinster, President of the Society, supported by the different Noblemen, Vice-Presidents, and Members of the Council, will fill the Chair. The Dress Boxes will be appropriated exclusively to Ladies.

The Premiums to be distributed on this occasion will amount to upwards of ONE THOUSAND POUNDS, and every facility will be given to the Exhibitors of Stock and Implements.

The AGRICULTURAL CHALLENGE CUP, Value ONE HUNDRED SOVEREIGNS, and now held by Geo. A. Grey, Esq., by his Short Horned Bull, Recruit, will be also challenged at the Meeting.

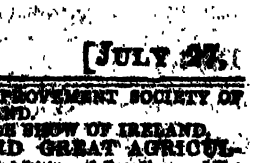
There will be an Auction of Stock in the Show Yard after the Show.

Places at the different entertainments will be specially reserved for strangers attending the Meeting.

The Society's Annual Report for 1843, and first part of its Transactions, are now ready for distribution, and may be obtained by members free, or by non-subscribers at One Shilling a Number, on application to Messrs. Curry and Co., Dublin; Fraser, Edinburgh; and Longman, London, the Society's publishers, who are making the necessary arrangements for its circulation all through the Kingdom. By Order, EDWARD BULLEN, Secretary.

Society's Rooms, 37, Upper Sackville-street, Dublin.

BY HER MAJESTY'S ROYAL LETTERS PATENT.



PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade. THOS. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

70, STRAND, LONDON.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6*, 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from table to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites, more wholesome and of less cost."—*Naval and Military Gazette, April 6, 1844.*

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

PRESERVES and CONFECTIONERY.—The superiority of BETTS'S PATENT BRANDY for PRESERVES and CONFECTIONERY, is testified by the fact that it is preferred to any other spirit by the most extensive WHOLESALE CONFECTIONERS in the METROPOLIS; for fortifying Home-made Wines it is invaluable; as an Ordinary Beverage it is congenial to the most delicate constitutions; and, as a Medical Stimulant, it is peculiarly adapted to persons of bilious or dyspeptic habits. Quantities of not less than Two Gallons, supplied at the Distillery, 7, Smithfield Bars, in Stone Jars, at 16s. per Gallon, exclusive of the price of the Jar; and in Glass Bottles, at 20s. per Gallon, Bottles and Case included.

CONSUMERS of BRANDY are respectfully informed, that J. T. BETTS, Jun., and Co., will not be responsible for any BOTTLED BRANDY that is not protected against fraudulent substitution, by the PATENT METALLIC CAPSULES, made of pure and solid metal (*not tin-foil*), embossed with the words "Betts's Patent Brandy, 7, Smithfield Bars," *to which attention is especially directed.*

FARMING INVESTMENT IN FRANCE.

TO LET ON LEASE for a long term, in the department of Soane and Loire, a FARM of 1250 ACRES, more than half consisting of Meadow Land, watered by two rivers. Situated about seven miles from a principal Town of 11,000 Inhabitants, and traversed by a main road through its broadest extent. The annual rental of the Arable Land, to be let at the rate of 6l. (6s. 8d.) per acre; the Pasture Land at the rate of 60f. (2l. 8s. 6d.) If preferred by the occupant, the uncut standing Grass might be purchased at the rate of 20f. (16s. 6d.) for 500 kilogrammes (1000 pounds weight), for the first crop, and at the rate of 10f. (8s. 6d.) for the 2d and 3d crops. The Proprietor would erect, at his own expense, the out-buildings required.

For further particulars, application to be made in London to G. B., personally, or by letter, No. 11, Manchester-street, Manchester-square.

WOODLANDS NURSERY, Blackheath, near Uckfield, Sussex.

VERBENA HUDSONII.

WM. WOOD AND SON, having purchased the entire stock of the above magnificent VERBENA, beg leave to solicit attention to Dr. LINDLEY's opinion of it in the *Gardeners' Chronicle*, July 6th, p. 445.

"*W. W. Hudsonii* is a good variety, bright rosy purple, with a white eye, distinct in colour." To which description W. W. & S. may be allowed to add, that the flowers are large and very showy; it has been seen by several competent judges, who have pronounced it to be a variety of first-rate merit. Plants will be ready for sending out on the 20th August next, packed in tin cases and forwarded post-free, at 2s. 6d. each, with the usual allowance to the Trade when six plants or more are taken at once.

A remittance will be expected from unknown correspondents.

The Gardeners' Chronicle.

SATURDAY, JULY 27, 1844.

MEETING FOR THE TWO FOLLOWING WEEKS.

Tuesday, Aug. 6 Horticultural . . . . 3 p.m.

ONE of the most curious things in cultivation is, that disputes should arise respecting the MODE of CONDUCTING OPERATIONS that must have been employed from the beginning of gardening; and that now, when so much real progress has been made in tracing effects to their causes, there should still be need of experiments to determine the nature of the very simplest phenomena.

Some of our readers may have remarked the commencement of a little discussion as to whether the sun will burn leaves recently moistened. Our answer has been, that it is a disputed question, and requires further examination. We have, we confess, made that reply in deference to the opinion of many excellent gardeners, who, when they find their Vine-leaves scorched, ascribe it to the leaves having had water standing on them when the morning sun has reached them. For ourselves, we entertain grave doubts as to the fact, for this simple reason, that when leaves are wetted by a sudden storm in the open air, even in the spring, and at noontide, when the sun is strongest and the leaves most tender, no scorching follows. Nobody ever heard of such a thing as wet leaves being scorched by the sun in the open air. It is only in glass houses that the mischief happens. How can that be?

That Vines are often scorched under glass, we all know too well; that the scorching may have followed the exposure of wet leaves to the sun, is possible enough; but the question is, Have the two facts any real connexion? The scorching might have happened, though the leaves were dry. That looseness of reasoning which obscures so many subjects is nowhere more conspicuous than in gardening, where *post hoc* is as often confounded with *propter hoc* as it is in physic.

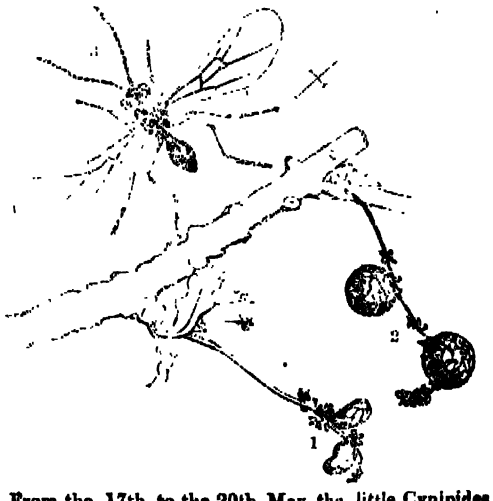
If the sun has the alleged power, there must be a reason for it, and accordingly what is called a reason is sometimes assigned. Water is said to collect in globules on the surface of a leaf, and so to concentrate the sun's rays like burning-glasses. But there are some rather serious defects in this explanation. Water does not necessarily collect in globules; and if it did, those globules could not act in a forcing-house with more energy than the dew-drops in the open air, which never burn plants. Moreover, the surface of a leaf is not in the focus of the imaginary fluid burning-glasses; and we need not say that the concentrated rays of the sun are only able to act when they are collected in a focus. Besides, when water falls on leaves, it assumes a plano-convex figure, and then, the convexity being uppermost, no focus can be formed.

Another reason that has been offered for the supposed phenomenon is that of M. De Candolle, who says, "I should think, *if the fact is as represented*, that this burning arises from the water softening the tissue below it, becoming heated by the action of the sun and hindering evaporation." But long before the action of the sun could have heated a drop of water high enough to cause a burning, the water would be dispersed in the form of vapour; and there is no evidence to show that leaves are scorched by the stoppage of evaporation. If it were so, leaves should be burnt the most when they are plunged wholly into water, which is the reverse of the fact. If they *are* hurt between sun and water, it seems more likely to arise from the cold produced by sudden evaporation.

The most rational course will be to verify the statement in the first instance, and then, *if it be a fact*, to seek for its explanation. It may be said, Why doubt that which is so notorious? One of the best and most sensible gardeners in the country, in a letter now before us, says, "I can assure you that my Vines have suffered materially from being acted on by the sun while moist from the syringing of the previous evening, and from the vapour generated in the house while shut close during the night." And he refers the mischief to his houses having been glazed with close-lapped British sheet-glass; giving it as his opinion, that in a house glazed with common glass, and open laps, it would not have occurred. This very statement seems to us conclusive as to the uncertainty of the cause of the burning. It may have arisen from the sun, or from want of ventilation, or from the vapour generated during the night, or, in short, from something else.

It is not difficult to meet these statements by counter assertions, also coming from excellent gardeners. Nobody grows much better Pines than Mr. Hamilton, who, however, "sprinkles their leaves with water two or three degrees warmer than the atmosphere of the house; and this mode of watering ought to be repeated *twice a day* in the summer-houses, *except in very cloudy weather!*" As the season advances, he waters the plants over the leaves whilst the sun is still shining on the glass, before its rays are much diminished. (*Treatise on the Pine-apple*, p. 65). Mr. Barnes also syringes, with water a little warm, occasionally on a fine day at any time. (*Loudon*, p. 700.) And yet, what is more common than to hear of Pine-plants being scorched by the sun shining on their wet leaves? Nor is the practice of wetting leaves at all times confined to certain Pine-growers. Mr. Roberts, whose Grapes have excited so much admiration at the London Shows, expressly declares—"Observe to keep up a very humid atmosphere, as under a clear sun the young foliage has a great drain upon it by evaporation, to a greater degree than when arrived at a more mature state. Syringe lightly, and close your houses early in the afternoon; say in March, two o'clock; April, half-past two; May, three; and so on, as the season and fruit advance to maturity." (*Culture of the Vine*, p. 47.)

We trust then that we have made out a case for inquiry. We would suggest the following mode of conducting it:—Take a Vine in very good health, in a well-glazed light vinery. Place a few of its leaves in exactly the same circumstances as regards the roof. In a bright day, wet some of these leaves, do nothing to the others, and watch the result. We shall then know if the burning is owing to the sun shining on wet leaves, or to some other cause. The first warm sunny day will settle the question; and we trust that many of our Vine-growing friends will tell us what they find to be the fact.



AN advertisement in another column will show the plan which will be adopted next Wednesday in regulating the MILITARY BANDS IN THE HORTICULTURAL SOCIETY'S GARDEN. In this country we know nothing of the surprising effects that may be produced in the open air by large numbers of military musicians. Next Wednesday, the assemblage of nearly 200 of the best in Europe will give some idea of what may be done in this way. No place near London of public resort offers so good an opportunity for trying the experiment as the Garden of the Horticultural Society.

THOSE who look at the progress of Gardening through the returns made in our columns of the proceedings of local and other HORTICULTURAL SOCIETIES, would come to the conclusion that it never was in a more flourishing condition than at present; and we think their judgment could not be gainsaid. Such returns are the best indications that we can have of the state of the public mind. But the more curious observer will remark something unsteady in these associations. Too often symptoms of feverish action are to be perceived, and not very uncommonly fatal cases are recorded. Although, upon the whole, the health of the body Horticultural is improved, yet it is evident that the care of the physician is occasionally wanted. A Society starts up to-day, flourishes to-morrow, languishes, and disappears. Why is this? To take an instance:—Nine years since there was no Horticultural Society in East Kent; when one was formed at Wingham, which still exists, although its funds are not so flourishing as they were. Another was shortly afterwards established at Dover, which flourished for four or five years, then languished, and finally expired. The following year a Society was started at Faversham, which ran about the same course, and is now defunct. Then succeeded one at Eltham, which after two or three years gave up the ghost. The city of Canterbury afterwards entered the field, and still continues to exist, but with three Shows in a year instead of four, as at first. The year before last another Society appeared at Ashford, which still continues, as well as one in the Isle of Thanet. It appears, in fact, that the majority of provincial Horticultural Societies have but a short existence, few, unless established in populous neighbourhoods, lasting more than ten years.

It seems to be well worth ascertaining the cause of these fluctuations. As the spirit for gardening does not abate in the localities where the Societies disappear, it is therefore to be presumed that there is something vicious in the constitution and working of the Societies themselves, which sends them so early to the tomb. A correspondent, who is well acquainted with their management, suggests that the best course to pursue would be to obtain returns from all parts of the country as to the past and present state of such Societies, their numbers, expenses, distribution of prizes, &c., and more especially as to the causes of their decline or dissolution, where they have experienced such mishaps. We agree with him in thinking that some very useful as well as interesting information might be so elicited; and we would, therefore, ask all Secretaries or Managers to communicate with us on the subject. To render the returns useful, and capable of being compared, it will be necessary that they should be made upon printed forms, which we will undertake to supply *gratis* to all who will do us the favour to apply for them, by post. Every man's labour will be thus simplified on the one hand, and rendered uniform on the other. A comparison of the returns will certainly throw much light upon the history of horticultural *eremacausis*, as Professor Liebig would call it; and a good digest of the returns, which we promise to make if the requisite materials are furnished, will, we trust, enable those who may hereafter think of organising local Societies, on the one hand to avoid error, and on the other to adopt regulations which multiplied experience shows to be advantageous.

ENTOMOLOGY.

THE CURRANTS OR GRAPE OAK-GALL, produced by *Cynips Quercus-pedunculi*.—I lately gave the history of the Woolly-galls, and this is another of the excrescences formed upon the flowering stalks of the Oaks, and by far the prettiest with which I am acquainted; much resembling in form, size, and colour, bunches of the Champagne Currant. Oak trees are sometimes covered as thickly with these galls as Currant bushes are with berries: such was the case last May at Wingham, in Kent, and at the same time they were abundant at Enfield, yet I could not find them in Suffolk or Essex this season; but they once occurred in Coombwood, Surrey, in profusion, and about the middle of May, 1841, I gathered the specimen figured, which was particularly interesting, from its showing, I expect, the process of growth in these galls: the flower-buds had been inoculated by the female Cynips, probably the beginning of April or earlier, and some of the stalks were yet green, and the anthers not quite dead; towards the extremity of one were two kidney-shaped galls (fig. 1) also green and wrinkled, in which I discovered minute white maggots; on another were the full-formed galls (fig. 2), globular, smooth, shining, and of a dirty pale-green colour, marbled with purplish red; in these the stalk and anthers were completely withered, and on opening the galls I saw the white pupæ, with black heads, lying in small cavities.

From the 17th to the 20th May the little Cynipides kept issuing from the galls. Linnæus described them under the name of Cynips Quercus-pedunculi, and the males, which first make their appearance, are intensely black and shining; the antennæ are nearly as long as the body, slender, brown, and 15-jointed: the basal joints are of a dull straw-colour; the head is broad, the eyes large, and there are three prominent ocelli on the crown. The thorax is finely striated obliquely, with two longitudinal grooves down the disc, interrupted and forming four pits; scutellum linear, long, rounded and elevated; petiole very short, abdomen not longer than the thorax, and much narrower, compressed; wings greyish, pubescent, and iridescent, superior very ample, the cells of the usual form, the basal nervures deep pitchy, with a small trigonate areolet on the disc; legs long, slender, and dull straw-colour; pulvilli and claws pitchy. The female is similar, but the antennæ are shorter and 14-jointed; the abdomen is shorter and almost as large as the thorax, ovate-conical, compressed, with an oviduct beneath, (fig. 3;) the natural dimensions are exhibited by the crossed lines.

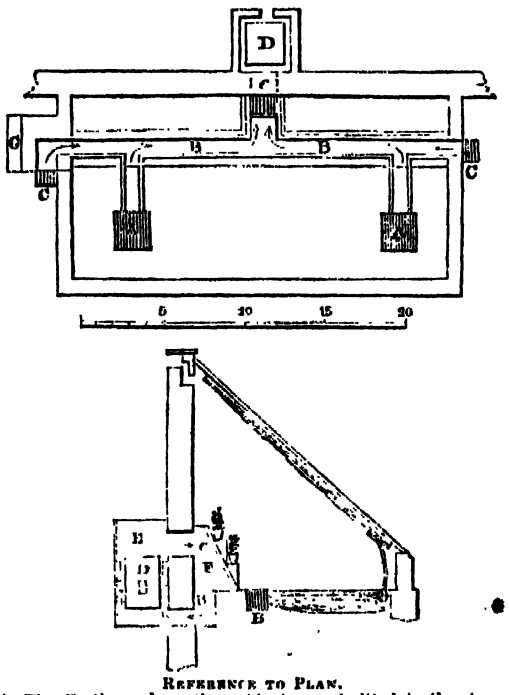
This species is less robust than many of the Cynipidæ are; the wings are large, the legs long, and altogether it seems to be well formed for flight. Mr. Main has made the following observation in the "Gardeners' Magazine" regarding this species, and it equally applies to the Woolly-galls; he says, "There is a remarkable fact accompanying the deposition of the

wise on the drooping stalk of the catkins. These male flowers are destined to wither and drop off as soon as their office of shedding the pollen is terminated; but if, before they have done so, they are seized and appropriated by the fly, they become permanent, and remain so until the maggot within the gall ceases to feed." From my own observations, as already recorded, it appears that many of the galls remain after the larva has become a pupa, and the same happens with the Woolly-galls, which are produced, as was lately shown, upon the male catkins of the Oaks; and the same difficulty presents itself in both instances relative to the deposition of the eggs by the summer broods, as we recently intimated, and which at present has not been satisfactorily accounted for.

These Cynipidæ are not free from the attacks of parasites, for I bred two very brilliant species from the currant-galls: one was apparently the Callimome flavipes of Walker, which is of a beautiful green with yellow legs, the ovipositor of the female being longer than the body; the other was the curious Platymesopus tibialis of Westwood. I am also now able to state that a pretty parasitic Chalcidideous insect has been produced from one of the Woolly-galls; several of both sexes were discovered in the box the 4th July, and they seem to be the Eulophus (Prosorus) similis of Walker.*

It will be remembered that the conglobated masses of twigs on the branches of the Birch, resembling swarms of bees and magpies' nests at a distance, also the mossy excrescences formed on the Briers, are the work of similar insects; which lately led to the suggestion, that if we knew the acids or poison which produce such remarkable objects, and the exact manner in which they are applied, it might be in the power of the philosopher to experimentalise with the same materials, and produce vegetable curiosities as interesting and ornamental as the Weeping Ash, &c. Let it not, however, be imagined that we prefer monstrosities to the simple beauties of nature, but every natural curiosity is worthy of investigation, if it be only in the search of truth; to unveil the mysteries of the creation appears to be one of the interminable subjects destined to exercise the ingenuity of man. —*Rusticola.*

PLAN OF A HOTHOUSE AT POLMAISE, STIRLINGSHIRE.



We have been favoured by Mr. Murray with the following plan and description of a hothouse, lately erected by that gentleman at Polmaise, and heated without the intervention of flues or hot-water pipes, but merely by a circulation of air from the hot-air chamber of a stove, behind the wall of the hothouse. Mr. Murray writes that "The hot-air is made to circulate freely through all parts of the house, at any temperature the gardener chooses, and a constant fresh circulation of air is kept up, by merely taking advantage of the well-known principle that hot air is lighter than cold air, and that therefore a circulation can easily be kept up by making the openings or drains one at each corner of the hothouse, and placing a grating on them, and conducting the drains under the surface of the earth of the house, into the stove placed at the outside of the back wall of the house, and introducing the air when heated in the hot-air chamber of the house, by means of an opening as low as possible through the back wall, into the house; but as the air of the house would soon be all returned hot into the house, two drains, one at each end of the house, are made, conveying fresh air also into the stove, and uniting with the two from each corner before entering the stove, and thus keeping up a complete supply of fresh air to the stove to come out heated air, to supply air to the plants in constant succession, and thus forming a healthy climate at any temperature the gardener wishes, with a constant circulation, but without any chance of injuring the Vines at any stage of their growth from the admission of cold air.

"In order to steam the house, a very simple process is adopted, by placing a woollen cloth along the whole length of the house before the hot-air chamber's opening, and watering the woollen cloth, thus producing a mild and gentle steam without any risk of its being too hot, as often happens when a flue is overheated and then watered. A stage for flower-pots is placed in front of the woollen cloth, which is stretched along the back of the stage sloping towards the back wall, the stage being about three feet at the bottom and 9 inches at the top. Indeed, the watering the woollen cloth has been found so beneficial a way of applying steam that some of the neighbouring gardeners have applied it over their flues, and watered it in place of watering the hot flue as formerly. I have also adopted another method of steaming the house, so producing a damp atmosphere, which is preferable. A sewer for conducting water runs along the upper board of the above-mentioned stage, and into the sewer are inserted worsted threads, which hang down a few inches on the woollen cloth—say five or six inches—and convey water gradually and constantly by means of the capillary attraction, thus keeping up any degree of moisture in the house that may be required, which is particularly beneficial during the swelling of the fruit, and can be regulated completely by the number of threads employed, and their thickness; and the water in the sewer is supplied from a small barrel standing at one end of the stage, which can easily be filled when required. Any degree of moisture may thus be given to the air of the house by increasing the quantity of heat, and regulating the supply of water through the

* Figures of the genera are illustrated in Curtis's Brit. Entom. pl. 132 and 562; also the Guide, Genera, 618, 622, and

worsted threads, and being given gradually in place of a rush of steam when hot flues are watered, it more resembles the natural moisture of the air, and is more healthy for the plants, and the moist air may be continued for any number of hours at a time, without any trouble to the gardener, exactly as he wishes it, and to any degree.

"The house has only been built two seasons, but the strength and healthiness of the wood of the Vines and foliage exceeds any in the neighbouring hothouses, or indeed in most others, and the bunches of fruit are quite magnificent. Much less fuel is required through the year—nearly a half—and less attendance. There is no chance of a flue choking, as there are none, or of a pipe bursting, as there are none; of course the original cost is saved, and the repair necessary for both avoided; the fire is made up at night, and requires no attention until morning. The stove used is one of Haydon's patent stoves; and the idea occurred to me of using it for a hothouse, from having heated a large church with a stove by the same maker—merely a circulation of hot air, without flues or pipes. Several professional gardeners have visited the house lately, and all have approved of the great simplicity and cheapness of the plan; and from the success attending it, there is no doubt of its being generally adopted: and the more so, as it is well known that the fruit is always higher flavoured when a free circulation can be adopted of fresh air, at a proper temperature; indeed, the fine bunches of fruit which were obtained last season were particularly high flavoured. The size and strength of the Vines are more like the growth of five years than two, and the foliage is in proportion."—*W. Murray.*

REFERENCE TO PLAN.

A. The Grating, where the cold air is admitted to the stove from within the house.
B. The Drain, conducting the cold air to the stove, over which is the gangway.
C. A Valve for admitting fresh air from without, keeping a healthy atmosphere within.
D. The Stove.
E. The Warm Air Chamber, and *e* the outlet from the chamber.
F. The Woollen Cloth nailed underneath a stage for plants which extends to within 2 feet from each end of the Vinery, dispersing the warm air equally through the Vinery, and steaming it by applying water through the rose of a watering-pan upon the cloth.
G. Steps into the Vinery.

HYBRID FERNS.

A TRANSLATION of some remarks on Hybrid Ferns, by E. Regel, in the "Botanische Zeitung" of August 11, 1843, may be acceptable to some of your readers; to these I have appended copious extracts from a letter on the subject received lately from Mr. J. Henderson, who has paid so much attention to these beautiful plants and formed so valuable a collection of them. As the observations not only of a scientific but of a practical man, they will, I am sure, be thought worthy of comparison with those of Regel, and the more especially as Mr. Henderson had not seen Regel's observations. Regel writes as follows:—

"The production of hybrid Ferns was first announced in modern times by Bernhardi. At present it is only in the genus Gymnogramma that such intermediate Ferns have arisen during cultivation, as may be regarded as hybrids. The arguments which speak for such hybridisation must be but negative so long as nothing certain is known respecting the mode of impregnation; for the views of Hedwig, Stöhelin, Œder, Schmidel, Kölreuter, Gärtner, and Mirbel, on the male organs, have been long regarded as unfounded. In like manner Bernhardi's and Presl's views are but hypothetical. The interesting discovery of Spermatozoa in Ferns lately made by my friend Dr. Nägeli, and which he will shortly publish, place the matter in a new light. Though the mode of impregnation may not have been discovered, still we have here a possibility of this process taking place. The negative ground, then, which speaks for hybridisation in the genus Gymnogramma acquires greater force. So long as a single species only is cultivated, each species of Gymnogramma remains constant under cultivation; but intermediate forms spring up from seeds where several sorts are grown. I have in my Herbarium, from the gardens of Berlin and Bonn, the following intermediate forms, which may be regarded as hybrids:—

"1. Between G. chrysophylla and peruviana, which is nearest to G. peruviana, as regards the mode of division and delicacy of structure; but the meal on the under side is of a somewhat duller yellow than in G. chrysophylla. This species is dispersed in gardens under the name of G. L'Herminieri. Whether it has arisen from culture, or has been introduced, I cannot speak with certainty; it seems, however, to be one of those Ferns which are apparently hybrids. It was distributed from the Leipsic garden through Germany.

"2. I have a plant between G. chrysophylla and G. distans, which was raised at the Botanic Garden at Berlin. In outline it resembles G. distans, but the pinnæ are broader, and the colour of the meal is dull yellow. Probably this is the same plant which was raised from seed at Erfurt, and named by Bernhardi G. chrysophyllo-distans.

"3. A third Fern, intermediate between G. chrysophylla and dealbata, is known in Gardens by the name of G. Martensii.

"4. Two Ferns are known to me between G. chrysophylla and G. calomelana, both of which agree in outline with G. calomelana. In the one the meal is of a greenish yellow; this goes by the name of G. Massoni, and seems to have originated in England. The second originated in the Berlin Garden, and has the meal as intensely yellow as G. chrysophylla. This I call G. chrysophyllo-melana.

"5. I have a Fern perfectly intermediate, both as to division and the colour of the meal, between G. distans and G. calomelana. It is from the Berlin Garden, and I distinguish it by the name of G. distanti-dealbata.

"6. I have two Ferns intermediate between G. dealbata and G. calomelana; one of which is nearer to the former, the other to the latter. The first is from the Berlin and Bonn Gardens, and named by me G. dealbato-calomelana; the latter, from Berlin, I call G. calomelano-dealbata.

"7. Lastly, I have a Fern intermediate between G. calomelana and G. distans, from the Berlin Garden, which I call G. distanti-calomelana. It is worthy of remark that these supposed hybrids are usually far more vigorous and larger than the parent plants.

"In conclusion, I beg leave to remark that if, in the absence of direct proof, these intermediate Ferns be regarded as mere varieties which have arisen from culture, we must for the sake of consistency suppose all the mealy species of Gymnogramma to have arisen from a single stock, which, if the extreme Ferns be considered, is very difficult to agree to."

Mr. Henderson writes to me on the subject as follows:—"I am afraid that I shall not be able to give you much useful information about Hybrid Ferns; it is a very perplexing subject, and all my inquiries in that direction have not enabled me to come to any decided opinion about the matter. Whether these plants are to be regarded as true hybrids, or the changes which they exhibit depend on peculiar circumstances affecting the individuals so changed, are questions which I think have not yet (as far as I know) been satisfactorily made out.

"I believe it is only in the genus Gymnogramma that those Ferns which are called hybrids have been produced from spores, appearing to partake of the characters of two different species. Among the hundreds of seedlings which are every year produced here, I have never in any instance observed a disposition to depart from the characters of the parent plant in any except those of Gymnogramma, and even these are confined to species the fronds of which have a farinaceous covering underneath. They differ chiefly in the colour of the farina, in the shape of the frond, and in having a much more robust habit than the species from which they are derived; they also produce few rather diminutive theca, with small imperfectly formed spores, which I think are mostly if not always abortive. I have sent you specimens of the different sorts that have been raised here; and also a specimen of G. Martensii, which was raised on the Continent, and which, in Link's Filices," is said to be intermediate between G. calomelana and G. chrysophylla. I have also within these few days received G. L'Herminieri, said also to be intermediate between these species, but it is evidently much nearer to the latter than the former species.

"No. 1 is between G. chrysophylla and G. sulphurea, the frond resembling the latter species in outline, but on a larger scale, and the farina approaching to the rich golden colour of the former species. Whether this is really an accidental variety or a species from foreign spores I am unable to say. Two or three seedlings came up here six or seven years ago—one in a pot among foreign seedling Ferns, and another in a pot with an orchidaceous plant: since then about a dozen more have been raised, all so perfectly resembling one another, that I am inclined to think that it is rather a species than a variety. It is by far the most graceful of all the farinaceous Gymnogrammas.—"No. 2 resembles much G. tartarea, but differs in its very large size, its more upright habit, and in the yellow farina.—"No. 3 bears nearly the same relation to G. calomelana which No. 2. does to G. tartarea. It grows to a very large size, nearly twice that of G. calomelana. Neither this nor the preceding have any resemblance to the species with yellow farina.—"No. 4 seems intermediate between G. calomelana and one that is known in gardens under the name of G. ochracea, a species from Buenos Ayres: the farina is paler than in G. ochracea.—I have a number of seedlings, all

closely resembling G. calceolaria, but with farina more or less of a yellow colour. G. calomelæna is, in fact, a very variable species in respect to the colour of its farina. I have hardly a plant the farina of which is free from a tinge of yellow."—*M. J. Berkeley.*

FAMILIAR BOTANY.

Morphology.—No. XVI.

By soft degrees a mighty change ensues.

Erratum.—P. 404, line 49 from the bottom, *for* "Each of these carpels is like that of the Whitethorn," *read* "Each of these carpels is like that of the Cherry."

The fruit of a plant is either merely its ripened carpel, or the ripened carpel together with the parts of the flower that surround it. A Peach is the first, an Apple is the second. This being so, and a carpel, together with the parts of the flower that surround it, having been demonstrated in former articles to be, beyond all possibility of doubt, altered leaves, it follows that the fruit of a plant is also a leaf or leaves. There is no getting away from the conclusion that is thus arrived at.

The changes that the carpel undergoes in the course of its change into a fruit are so numerous, that it would be tedious to discuss them in detail. The alterations that result in the formation of a Peach may be taken as an illustration of the process in other cases.

When the flower of a Peach drops off, the carpel loses its style and stigma, which are no longer wanted, and the ovary alone remains to swell and change. It is to be recollected that that ovary consists of the two sides of a leaf turned inwards, and united at the edges; consequently, one side of it answers to one half of a leaf, and the other side to the opposite half. Now, it is not uncommon to find one half of a leaf green and the other white, or to have the two halves different in some other respect. In the Peach the carpellary leaf is, in like manner, occasionally found to be smooth on one half, and downy on the other; and then, when such a carpel becomes a ripe fruit, one half is a Nectarine, and the other a Peach. This is not of uncommon occurrence, and is clearly intelligible upon morphological reasoning, and upon no other.

Vegetable anatomists also know that the leaf of a Peach-tree, although as thin as a piece of paper, consists in reality of two layers, of which the uppermost is much more compact than the other, in consequence of its component parts being differently arranged. Now, the inside of a Peach is the upper side of the leaf out of which it is fashioned, and therefore may very well be the hardest, as, in fact, we find it to be: for the stone of the Peach is its inside.

When the carpel of a Peach swells, its sides thicken, and soon acquire the texture of brittle leather; by degrees the apparent uniformity of the materials out of which the sides of the Peach are organised cease to present a uniform appearance. The inside (or upper side of the carpellary leaf), becomes paler and firmer; and thus the stone originates. Those who put green Peaches into pickles know this, for such Peaches are unfit for the purpose as soon as a pin refuses to pass easily through them. Gardeners know it still better; for the time when the hardening of the inside of the Peach takes effect is the critical period in the life of the young fruit. At that time the colour of all the parts is the same, or nearly so; it is only by its greater hardness that the future stone is to be known. But by degrees two opposite changes take place in the two layers of the Peach; the outer becomes more and more soft, acquires great succulence, changes colour, and ends in the flesh; the inner becomes more and more hard, acquires considerable dryness, and ends in the stone. In some Peaches the two layers, one flesh and the other stone, freely separate; in others they as firmly adhere—as we all know.

It is thus that a Peach is made out of a leaf in the form of a carpel; and a similar investigation so completely explains the formation of all other fruits, that I shall pursue the matter no further. There is, however, a class of facts connected with certain kinds of fruits, so intimately connected with this subject, and so conclusively establishing the exactness of the views of morphologists, that they may not be passed by in silence.

Every year we remark occasional instances of an Apple or a Pear lengthening out, and acquiring the appearance of a Pear within a Pear. Mr. Peter Mackenzie sent us in 1842 a very curious instance of the sort in a Crassane Pear; and in the same year Mr. Henderson, of Brompton, forwarded a Chasmomtella equally instructive, a figure of which is here introduced.

It had lost entirely its usual form, instead of which it appeared to be constructed with scales arranged one over the other, in the manner of a Pine cone. Nothing can be clearer than that in this case the leaves of the calyx and corolla had increased somewhat in number, the centre round which they were first arranged having lengthened out a little. The effect of the lengthening was to separate the leaves a little, and to raise them somewhat one above another; so that, when the lengthening process took place, their ends projecting one beyond the other would necessarily assume the appearance in the woodcut. If a leaf-bud lengthens a little, this is what happens; and there is no conceivable reason why a flower-bud, which is the same thing in another form, should not also lengthen in the presence of disturbing causes.

What those causes are I shall leave the Editor of the *Gardeners' Chronicle* to explain when he shows, as he one day will endeavour to do, how important a connection there is between Morphology and Gardening.—*R. E.*

NOTES ON AMERICAN PLANTS.

Having, during the spring of 1843, joined a party of gentlemen at St. Louis, state of Missouri, who were bound to the Rocky Mountains on a hunting excursion, and as Botanical pursuits were my sole object, I have thought it might gratify some of the readers of the *Chronicle* to learn a few particulars respecting the localities of the various genera that came under my observation; at the same time I must remark that this is very deficient as a list of the flora in the regions which we traversed. Our movements were too rapid to afford a fair opportunity for exploring many of the most favourable localities, and although I daily travelled at least one-third more than the rest of the party, still I was not able to examine the country as I could have wished.

We left the city of St. Louis on the 2d of May, and proceeded up the Missouri by a steam-boat, a distance of 360 miles. The banks of this noble river were beautifully ornamented by the Cercis Canadensis, which displayed its purple flowers in the greatest profusion. Among the herbaceous plants, I observed several species of Viola, the Podophyllum peltatum, two species of Habenaria, some Oxalis, Corydalis, and Anemone Pennsylvanica; but the spring having been unusually backward, Flora had not then displayed many of her treasures. We reached Westport on the 8th of May. This is the Ultima Thule of civilisation; and, as henceforward we had to travel by land, we had to encamp until the 21st in order to make the necessary arrangements for prosecuting our journey. This delay afforded me a good opportunity of examining the country around. The following embrace such plants as came under my observation, viz., Claytonia virginica, Batschia canescens, B. longiflora, B. Gonelina, Corydalis cucullaria, Baptisia leucophæa, B. leucantha, B. cœrulea, Krigia dandelion, Erythronium albidum, Sisyrinchium mucronatum, with its varieties; Pastinaca fœniculacea, Cypripedium albidum or candidum, C. parviflorum, C. pubescens, Oxalis violacea, Hyporis erecta, Astragalus caryocarpus, Cercis Canadensis, Viola cucullata, V. pedata, V. delphiniifolia, and Verbena Aubletia.

During the first week of our journey, which comprised only a distance of about 100 miles, being from Westport to the Kanzas River, the chief plants were Phalangium esculentum, Ellisia Nyctalea, Psoralea esculenta. The Baptisias leucophæa and leucantha, with Batschia canescens and B. longiflora, were most profusely spread over the rich undulating prairies we traversed, and gave the whole scenery a gay—nay, even a brilliant appearance. The Eryngium aquaticum was the plant that most prevailed, but it was not then in flower. The soil here was very rich, and the country was particularly well wooded along the margin of the various streams which intersected the prairies, comprising the Ash, several species of Elm, Hickory, various Oaks, the American Pappaw, Chesnut, Beech, Birch, and Poplar. From the Kanzas River to the River Platte, which we reached on the 14th of June, the Phlox aristata, Astragalus adsurgens, Pentstemon grandiflorus, and another species, with the Sida coccinea and Gaura coccinea, displayed their rich blossoms in the greatest profusion. The latter plant has a beautiful rosy shade in the morning, scarlet towards noon, and nearly a white in the evening, when it emits a most agreeable odour. This plant and the Gaura coccinea continued to produce their rich blossoms until we reached the Sweet-water of the Platte, a distance of nearly 800 miles. While travelling over this region, I found a beautiful crimson Malva, or Nuttallia. The following embrace the principal plants which came under my notice during this part of our journey:—Lathyrus ornatus, Oxytropis Lamberti, Liatris pycnostachya, L. punctata, Salvia azurea, Psoralea esculenta, P. floribunda, P. canescens, Cassia chamæcrista, Rosa blanda, R. foliolosa, Phalangium esculentum, Monarda oblongata, Corcopsis tripteris, C. palmata, Tradescantia virginica, with varieties from the purest white to the darkest purple; Zizia aurea, Pedicularis canadensis, Anemone Pennsylvanica, Clematis viorna, Fragaria sp. (?), Symphoricarpus vulgaris, Gerardia angustifolia, Seymeria macrophylla, Lilium unifloxum, Lythrum virgatum, Phlox divaricata, P. suavsolens, Senecio aureus, Oxybaphus (Calymenis) Nyctaginea, Talinum parviflorum, Malva pedata, M. involucrata, Cnnothus mollissimus, Psoralea argophylla, Petalostemon violaceum, Desmodium acuminatum, Schrankia uncinata, Darlingtonia brachypoda, Geum virginianum, Potentilla arguta, Polytænia Nuttallii, Œnothera speciosa, and others. We now commenced a tedious and uninteresting journey along the plains of the Platte River, and for several days the flora on the plains was very meagre, if I except two species of Mammillaria and the Opuntia Missourica, O. cylindrica, with a fine variety of Grasses. On the 21st of June we ascended to the upper prairie, when a gay floral scene was presented to our view. The rich yellow of the Coreopsis tenuifolia predominated, but was enchantingly variegated with the white bloom of the Pentstemon albidus, the scarlet of the Sida coccinea, the various shades of the Tradescantia virginica, and the different species of Astragalus, diverging from the purest white to the darkest crimson. From the south to the north fork of the Platte, I observed the most Erysimum argenteus, Lupinus pumilus, L. sp. (?), Erysimum asperum, Erysum pusillum, Cleome integrifolia. Several plants were found in this region which were entirely new to me, particularly a dwarf shrubby Œnothera, the finely-pencilled rose-coloured flowers of which were very much admired. I also observed Lathyrus linearis, Cœnothus Americanus, Amorpha fruticosa, Oxytropis Plattensis, Œnothera rhombipetala, Vernonia fasciculata, Aster cordifolius, A. oblongifolius, A. Novæ Angliæ, Duteria coronopifolia, D. pulverulenta, Erigeron bellidiastrum, E. glabellum, E. strigosum, Coreopsis tinctoria, Lobelia spicata, and L. siphilitica. On the 27th of June we made the North Fork of the Platte; the surface of the ground became more varied; rocks began to make their appearance, with a range of hills composed of soft marl of an earthy formation, and consequently plants were more abundant. As we descended from the upper plains a variety of species were found, among which may be enumerated a species of Oxybaphus (?) or Calymenis (?) Œnothera pinnatifida, O. speciosa, Yucca angustifolia, a most beautiful species of Eriogonum, Œnothera albicaulis, O. trichocalyx, O. biennis, O. Drummondi, O. coronopifolia, O. cæspitosa, O. pinnatifida, with several other unknown species; Potentilla anserina, P. arguta, Thalictrum megacarpum, Argemone Mexicana var. albiflora, Helianthus two species; Nasturtium palustre, and among the hills a beautiful crested Pentstemon. This brings me to Fort Laramie, a trading station of the American Fur Company. From thence to the Sweet-water of the Platte, among other plants may be mentioned a pretty species of Aster, three species of Calochortus, and Gaillardia bicolor. At a small stream called Bitter Creek, several acres were densely covered with a species of Delphinium of the richest azure blue, and most agreeable odour; Pachypodium integrifolium, Vesicaria didymocarpa, Polygala alba, Linum rigidum, Pelargonium Fremontium, Rhus triloba, Purshia tridentata, Glycyrrhiza lepidota, Apios tuberosa, Psoralea campestris, P. tenuifolia, P. lanceolata, Petalostemon candidum, P. villosum, P. violaceum, Astragalus gracilis, Phaca longifolia, and several other species; Kentrophyta montana; Lupinus, four species; Cerasus Virginiana, Campanula rotundifolia, Rubus strigosus, Epilobium coloratum, E. spicatum, Mentzelia nuda, Ribes cereum, R. lacustre, R. irriguum, Sedum rhodiola, Sium inciaum, Cornus stolonifera, Symphoricarpus occidentalis, and Galium boreale. On the 17th of July, while all were occupied in crossing the North Fork of the River Platte, I paid a visit to the highest range of the Black Hills, a distance of eight or ten miles, and was rewarded by finding several species of Euchroma (Castellejas), Claytonia virginica, on the margin of a dense mass of snow; species of Silene, Cerastium, Viola, Pelargonium, Lupinus, Frasera, Erysimum, Œnothera, Batschia, Geum, Pinus, Abies, Juniperus, and the beautiful Lewisia rediviva, with several unknown genera.

On reaching the beautiful winding stream called the Sweet-water of the Platte, we found we were fast approaching the mountains. While passing through this arid region, days would elapse without our finding a single plant that was worthy of notice. The whole ground was literally covered with different species of Artemisia. In many instances the floral goddess seemed to have deserted us. However, in more favoured spots I was enabled to enumerate the following, viz.:—Brickellia grandiflora, Aster multiflorus, A. falcatus, Erigeron canadense, Gutierrezia euthamiæ, Solidago rigida, S. Missouriensis, S. speciosa, S. giganteu, Aplopappus spinulosus, Grindelia squarrosa, Franseria discolor, Helianthus petiolaris, H. Maximiliani, Cosmidium gracile, Bidens connata, Hymenopappus corymbosus, Artemisia Ludoviciana, A. frigida, A. canadensis, A. cana, A. biennis, A. Lewisii, A. rediviva, Stephanomeria runcinata, Gnaphalium uliginosum, G. palustre, Cacalia tuberosa, Mulgedium pulchellum, Lygodesmia juncea, Glaux maritima, several species of Pentstemon, Teucrium canadense, Lycopus sinuatus, Stachys aspera, Scutellaria geniculata, Mentha canadensis, Lippia cuneifolia, Onosmodium molle, Myosotis glomerata, Phlox Hoodii, Polemonium cœruleum var., Calystegia sepium, Gentiana affinis, G. Fremontii, and two other species; Frasera speciosa, Asclepias speciosa, and three other species, Kochia dentata, Eurotia lanata, Fremontia vermicularis (I believe the Batis vermicularis of Hooker), Oxybaphus sp. (?), Polygonum persicaria, P. aviculare, P. viviparum, Rumex sp. (?), Shepherdia argentea, S. canadensis, Sisyrinchium anceps, Iris Missouriensis, Allium reticulatum, Smilacina stellata, Zigadenus glaucus, Eriogonum annuum, E. umbellatum, E. Fremontii, E. cæspitosum, E. ovalifolium, and three other species; Gentiana aretophylla, Elæagnus argentea, Polygonum amphibium, Gilia sp. (?) (splendid), Pulmonaria ciliata, Pedicularis surrecta, Castelleja pallida, C. miniata, and two other species; Mimulus sp. (?), Orthocarpus luteus, Dodecatheon dentatum, Arctostaphylos uva ursi, Senecio triangularis, Helianthus uniflorus, Balsamorrhiza sagittata, Iva axillaris, Phaca ternata, Aster integrifolius, A. adscendens, A. novi Belgii, A. elegans, Potentilla gracilis, P. fruticosa, P. diversifolia, P. sericea, Sibbaldia procumbens, Thermopsis montana, Astragalus hypoglottis, Parnassia fimbriata, Arenaria congesta, Berberis aquifolium, Actæa rubra, &c.

The above names are according to Dr. Torrey, who had the arranging and naming of a collection of specimens collected by Lieut. Fremont, of the U.S. Army, and who had gone over our route, in a great measure, during the summer of 1842.—*Alexander's Gardens, London.*

Home Correspondence.

Summer Pruning.—In the case of the Gooseberry this is frequently neglected, but it is worthy of attention for several reasons. The first is, that by cutting off the summer shoots a greater proportion of sap is directed to the fruit. Where summer pruning is not performed this is lost in the production of useless spray and foliage, which moreover retards the swelling and ripening of the fruit by shading it from the influence of sun and air. Pruning is, on that account, necessary, in order to have large, well-flavoured berries; and it also, by concentrating the sap, in a great measure aids the formation of more fruit-buds for next year, and renders them more vigorous and healthy. The shoots, however, ought not to be cut off too early, as this would perhaps cause the tree to push new shoots again instead of forming fruit-buds; neither would I prune to the base of the shoots, as that would cause the buds at the bottom to push, and perhaps convert some of those formed for fruit into wood buds. My plan is to begin about the end of June or beginning of July (according to the earliness of the season), and cut away all the suckers from the bottom of the bush pretty closely. I then cut off the summer wood along the main branches with pruning-shears, which are speedier than a knife, cutting more or less off the shoots, according to their strength—say about half off a weak shoot, and one-third off a strong one, or perhaps less, it being best to err on the safe side. In some cases merely pinching off the points is sufficient, for by taking too much off you may cause the shoot to push anew. If after this pruning the bushes make more new wood, they may be looked over and the young shoots topped, but take care not to top the leading shoot of a main branch when the bush is young, and has not arrived at its full size. Another reason in favour of summer pruning is, that it makes the bushes have a much neater appearance; it also leaves less shelter for the caterpillar and other vermin. All the young shoots that are thus stopped should be pruned back to one eye in the winter or spring pruning. With regard to the summer pruning of Apple and Pear trees the same remarks are applicable. In pruning these it is common to cut the young shoots close to the spurs, or to rub them off as they appear; but this is a practice of which I do not approve, for by so doing more young wood is always encouraged, and consequently fewer fruit-buds are formed. My method of pruning wall or espalier Apple and Pear trees is this:—I never rub off the wood-buds, but let them grow until the month of June or July, when I go over the tree and shorten the shoots according to their strength and vigour. When young shoots appear after that time, do not rub them off until they are of considerable length, otherwise they would push again, and carrying off the sap, would impair the vigour of the fruit-buds. Thus, by stopping the summer wood in proper time, new fruit-buds are formed, and the others are more matured for the succeeding spring. Some may object to the untidy appearance of the trees on walls having part of the young wood sticking out, and may say that it in a great measure deprives the fruit of the full influence of the sun. But this is not the case, as a moderate shading is not against fruit, and the productiveness of the trees will fully compensate for the untidy appearance. If the above method was fully practised, we would hear of fewer complaints about bad crops on wall and espalier trees.—*A. W., Muiryfold Grange, Banffshire.*

Canker in Fruit Trees.—In April, 1843, I worked some grafts of the Crofton Apple on a young stock; they went through the usual process remarkably well: and when I removed the clay, &c. everything appeared in a healthy state. On examining the stock during the following spring, 1844, I found it so extensively cankered that I was obliged to cut almost through it, in order to eradicate the decayed parts, leaving but a small portion of the back. Fearful of losing my tree from the dryness of the season, and hoping to induce the wounds to heal, I covered the stock up to the grafts (about 16 inches) with rich soil The result of my experiment has been most satisfactory. The injured parts are forming new bark round the edges, and the stock is throwing out beautiful roots from the eye below the grafts.—*Falcon.*

Pear-Pruning, by "Observer."—Before his well written observations are acted upon, one should like to have Dr. Lindley's opinion upon his mode of pruning, as well as that of the leading gardeners, through the medium of the *Chronicle*.—*July 13th*, 1844.

Quick growth of the Pear.—I have in my garden two grafts of the Gansel's Bergamot, and two of the Beurrée D'Aremberg (worked on a Windsor Pear stock in April, 1843), now covering one hundred feet of wall. Is not this rather an extraordinary instance of quick growth?—*Falcon.* [Very.]

Pears.—The introduction of so many good kinds of Pears of late is a very great acquisition. Some of them not only surpass many of the old kinds in flavour, but also in fruitfulness, even in situations where some of the old sorts do not bear well. Witness, for instance, the fine fruit of Napoleon or Marie-Louise, on a north-west wall, where the Crassane and Brown Beurré are cracked and gritty. The Marie-Louise succeeds better on a west or east aspect than on a south one; this is owing to its being retarded in such situations until the weather becomes warmer; it blooms too soon when exposed to the south, and consequently suffers from cold and frosty winds. Many of these lately-introduced varieties keep much longer than the old ones. When this is fully known, we need not be surprised to see Pears take the place of Peaches and Nectarines, which are difficult to keep, especially in late seasons. Though the fruit of both are excellent, yet they are of short duration; while a good collection of Pears will last during winter and spring when fruit is most wanted. It is not unusual to see fine walls covered with old barren Pear-trees, which might be rendered fruitful if they were grafted with new kinds. I observe in a back Number of the *Chronicle* an opinion by Mr. Hayward respecting ripe Pears. He says—"No Pears, if gathered and eaten when fully ripe on the tree, are so good as when gathered as soon as they have attained their full size, and laid by in a dry place until they are ripe." This writer surely cannot mean that Pears ought to be gathered immediately when they attain their "full size." I consider it is better to let them hang on the tree until they give warning by dropping, or until their stalks part freely from the tree; for, in my opinion, many of them, and especially late kinds, are gathered too soon. At present (Nov. 7), I have several kinds of Pears yet on the trees; they seem to be improved in quality. If Pears are gathered too early they become tough and wizzened.—*J. Wighton.*

Gooseberry Seeds.—This is the proper time to sow Gooseberry seed. This season has been very favourable for the finest and most delicate sorts to ripen; and I would recommend those who wish to obtain improved varieties to sow the seed in shallow seed-pans, placing them in a cool frame; the seed can be separated by mixing fine sand with the pulp, and rubbing it out. This operation over, sow immediately, and keep moderately moist the soil in the pans; when the seedlings are up, and have got four leaves, let them be exposed altogether to the weather; but I would advise their being kept in the pans, and again placed in a cold pit, and finally planted out in rows, 2 feet apart. In the spring they will fruit the second year.—*Anon.*

Gooseberry Caterpillar.—Among the many prescriptions for getting rid of this troublesome pest, is one which, for simplicity and efficacy, cannot be made too well known. It is this:—When the bushes are wet, either after a shower or after having been watered with a garden-engine or watering-pot, dust them over with a little dry soot. The caterpillars desert them immediately after the application, and the first shower cleans the bushes of the soot.—*D. F., Woodhouselee.*

Pruning Forest Trees.—In a late *Chronicle* I observe a remark, made by a writer signing himself "Quercus," to the effect that, with reference to the growth of Oaks and the pruning of them, "he never yet saw a magnificent stem that had not a proportionately large head." But I would beg to ask him whether he has not seen many a magnificent head that had not a proportionate stem? I well know that I have, and that I have indeed now some such in my view; yet would I not on any account have that disproportion in them altered, forming as they do an ornamental feature in my grounds; though in respect to others growing in a coppice, where ornament is not such an object, I would gladly exchange the branching honours of their heads for the solid cubic contents of a long stem, from which, when felled, the builder might be able to cut his stout beam and girder, of 25 or 30 feet in length. Every one, doubtless, loves to behold in the rich domain a magnificent Oak, extending far and wide its enormous branches, as if to protect the soil that had nourished its increase, and enabled it to withstand the storms of many centuries. Few objects in the creation present a more imposing spectacle. But for useful purposes, surely it were desirable to grow clean straight timber; and if the zealous planters of the present generation were but to plant Oak more largely (instead of the Beech, and other trees of little use except for fuel), I cannot but think it might again become sufficiently abundant to be extensively used, as formerly, in our buildings, in lieu of the perishable material now generally employed. But such timber can only be obtained by paying more attention to young plantations than is usually bestowed upon them: in the first place, with respect to thinning; and, secondly, by judiciously pruning the young trees. By the neglect of the first operation, the Larch, and other trees that should nurse the Oak in its infancy, will very soon altogether destroy, or sadly weaken it; and, for want of pruning, numbers of the young trees will remain stunted from want of nourishment (except, perhaps, in very congenial soils), or distorted in their growth by the irregular diffusion of the sap among the branches, and the consequent want of a vigorous leading shoot. Having had the experience of near forty years as a rather extensive planter (during which I think I may say I have personally given more attention to the subject, and especially to pruning, than most gentlemen), I will venture boldly to affirm, that increased vigour, stature, and bulk, will ever be the sure result of the judicious pruning of the Oak, whatever any theorists may advance to the contrary.—*W. H.*

Action of Roots.—In illustration of the fact that plants draw all their nourishment from the small roots at their extremities, and are little, if at all, affected by having the larger parts exposed to the weather, I have lately had a convincing proof. In repairing a vinery, I was desirous to have the front wall, which was originally of solid brick-work, built on arches, for the benefit of some of my best Vines. They are planted in the inside of the house, but I have some on the outside likewise, which I wished to retain until their places are supplied with young ones. From these it was necessary that all the soil should be removed; and knowing that it was a stiff adhesive clay, and that there would be few small roots close to the stem, I commenced at it and removed the soil away for a distance of three yards. In that state the roots lay exposed from the end of March to the beginning of May; nevertheless I find that the Vines have broken as strong as usual, and show about the same quantity of Grapes.—*J. M.*

Plant Brokers.—If a new plant could be as readily got as a new book, the trade would be benefited. Why should not there be brokers, who would undertake to execute an order for plants raised in the neighbourhood of London, just as a wholesale bookseller in town executes an order from the country, though it may be for not a single book of which he is the professed publisher? The present system of the trade acts as a check upon their own profit, no less than the grievous charges made by carriers for parcels of small weight.—*Richard Tongue.*

Acclimatising Plants.—I am of opinion that many of our greenhouse plants, particularly those from the Cape, may be cultivated in the open air, even in our uncongenial climate, with greater success than is generally supposed. In proof of this, I planted out last autumn two plants of Cacalia, one ficoides, L. and the other articulata, on a small rock-work, at the end of a vinery. Not being disposed to take them up and reset them, I left them to take their chance. While they were out of doors a sharp night's frost set in, with a cold and high wind. I naturally expected to find the plants destroyed, but upon examination, I found that they were not the least injured. When the next frost appeared, I covered them with a little hay, which was removed as soon as the frost went away, and now the plants are growing freely. Along with the Cacalias was a plant of Aloe succotrina, (De C.), the leaves of which were destroyed, but the roots were spared, and are now sending up two fine suckers. While speaking of this species of Aloe, I may observe, that the leaves of this plant are much sought after here for burns, &c.; the leaf is cut in half, lengthways, the fleshy side is then laid upon the burnt part, and it is said that it greatly abates the pain. So much are these leaves sought after by the inhabitants of Hillsborough, that our plants are greatly mutilated by cutting off the leaves for them. Now, if these fleshy-leaved plants will survive our winters with a slight covering, why not hard-wooded plants, from the same country? At the same time, I put out a plant of Goodia lotifolia. This stood a frost of 5° without the least protection, and in a very exposed situation, but the second frost, which was very severe, and of long duration, killed the plant to the ground; but upon examination, I found the root, and that part of the stem which was under the ground, as fresh as when planted; and I have no doubt but that the roots would have sent up suckers, which this plant is very apt to do, if it had been left in the ground. I ought also to mention that the shoots were of one year's growth, and quite tender, which was greatly against it. I am, however, fully convinced that if the plant had been protected, it would have survived the winter. The Clianthus puniceus stands out here against the end of a vinery, with a very slight protection, and that only on very severe nights, and flowers abundantly in spring. I would recommend this plant to be cultivated as a standard in sheltered situations in flower-gardens and pleasure-grounds. It should be protected with a few Fir branches, or old mats; its beautiful scarlet flowers in the spring months will amply repay the trouble. Azalea indica alba also stands out here in the flower-gardens, and flowers freely, with a few Fir branches laid over the tops of the branches on very severe nights; this plant is generally cultivated in the greenhouse, summer and winter. It will, however, thrive much better if kept, during winter, in a cold frame or pit; when wanted for flowering, it should be placed in the greenhouse. I formerly stated that Fuchsias ought to be abundantly cultivated in the open air: of the importance of this I am every day more and more convinced; and it is my opinion that they ought all to be thus treated, with the exception of those which are intended as specimen plants, for exhibitions, &c.; but for the tender species and varieties, I would recommend a covering of old tan, short dung, or a spadeful of earth, to be laid over their tops after they have been cut down. F. fulgens stood out this winter here, protected in this way. Now, if fulgens, which, in its young state, is amongst the softest-wooded species we have, stands out with a slight protection, why not others of a hardier nature? I trust that these observations will induce some of your correspondents to give the results of their experiments on this subject; for I feel confident that we shall hear of plants which are now choked up in greenhouses, growing freely in the open air with little or no protection during winter; and of those plants which are now burnt up in a stove, growing and flowering freely in the greenhouse.—*John M'Intosh.*

Influence of the Moon on Plants.—A notion was formerly very prevalent among gardeners, and perhaps exists to some extent at present, that the light of the moon has an injurious influence upon plants, particularly in the months of April and May. The name of *Lune Rousse* is given by the French to the April moon, from the influence it is supposed to exert on the leaves of plants, in turning them brown. M. Arago has shown that this notion is erroneous, the effect alluded to being clearly owing to another cause, but one which must necessarily be in active operation on bright moonlight nights. He observed that in the months of April and May the temperature at night is often not more than four or six degrees above the freezing point; and under these circumstances, when the sky is most unclouded and the moon shining brightest, heat will be radiated from the earth sufficient to reduce the temperature at the surface some degrees lower, or below freezing point; hence the tender leaves and roots of plants are nipped by cold, and that appearance given to the former which is intended to be conveyed by the French word *rousse*. I have been induced to offer these observations from

the practical bearing which they appear to have on the subject of morning and evening watering of plants; and I imagine that it is consistent with a just view of the subject to affirm, that in regard to out-of-door plants morning watering alone should be resorted to during the spring months, even to the end of May in our uncertain climate. We cannot prevent the refrigerating process which more or less is going on at the surface of the earth in the cold clear nights of spring; but we may, at least, avoid artificially assisting it by putting the earth just in the most favourable condition for producing cold. It is so placed, when the surface is newly watered, because evaporation, and consequently congelation, is most active when it is in that state. I may illustrate the comparative influence of morning and evening watering, in relation to this subject, by what takes place when several folds of wetted cloth are applied to a vessel to cool the contents. As long as the outer cloth is wet, the evaporation goes on unobstructed and the temperature of the vessel is proportionably reduced; but as soon as the external covering loses its moisture, the process languishes, though the inner folds are still wet. So in morning watering, the surface moisture is evaporated in the genial temperature of daylight, without injury to the plants, and when night comes on, the surface is comparatively dry, and evaporation cannot go on so actively, however clear the atmosphere. In evening watering, on the other hand, we prepare the ground for an energetic evaporation going on during the night; consequently chilling the earth and plants growing in it, at a time when the low temperature of the air is more than sufficiently adverse to the well-being of the latter.—*J. H. H.*

To keep Shrubs from Windwaving.—Among the different methods that have been used to prevent injury to transplanted shrubs, arising from their being shaken by the wind, the simple plan of pegging down their lower branches seems to be the cheapest and best. The forked pegs used for this purpose should be made with one side about half the length of the side from the principal branch, and a head six or seven inches in length should be left for the prevention of splitting, on being driven into the ground. In hard ground the holes, especially for large plants, should be opened with an iron bar, to save labour in driving, and waste of forks. The elasticity of the branches when well secured, preserves the removed plant remarkably steady during the action of heavy gales of wind, and if the ball of earth is of moderate size, and of the usual proportion to the size of the shrub, it is singular how small a twig is sufficient to support it in bad weather. The branches may be cut, and the pegs removed from shrubs near walks, towards the end of the ensuing summer; in other cases they may be left to die, or grow and form layers for masses of shrubs, according as light and air are admitted or excluded. Ropes give and take in dry and wet weather to such a degree as to be useless as stays. And even the fastenings of pole stays are almost sure to become loose enough in dry weather to allow the bark to be chafed. Stays of all kinds ought to be applied whenever practicable to the branches, rather than the main stem; and each stay should have a separate fastening. Comparatively little injury is done even if the bark of branches is compressed too much, or rubbed, and in many cases branches by such means may be weakened to the improvement of the plant. Under circumstances where expense is a secondary object in the removal of valuable trees or shrubs, or it is of consequence to secure common trees, iron-wire stays of $\frac{1}{10}$ to $\frac{3}{10}$ of an inch in diameter, with a stuffed clip round branches secured to pegs, or to posts, if cattle were admitted round the trees, would form a secure fastening capable of lasting a considerable period, and of being used for different trees in succession, in which case its cost would be much less than rope. In reference to the success of transplanting shrubs or trees at different periods of the year, if parties took more notice of all the circumstances attendant on their removal, perhaps several points of greater importance might be observed, for instance:—1. Removal from a greater to a less exposure, for the sake of obtaining a free growth of leaves, which are of greater importance even than roots. 2. Removal from worse to a better ground, either natural or artificial. 3. Removal to land which can be readily penetrated by the young roots of plants; the easiest means of obtaining this essential quality is by mixing loose stones of any kind with the soil; when the tree or shrub gains strength it will usually take care of itself. 4. The removal of trees or shrubs in a healthy but not luxuriant state of growth; cutting round the shrubs some time previous will soon cure the latter defect, and insure subsequent success. It is most valuable in all cases, but occasionally it will be advisable to encourage the growth of fresh roots by good or rich earth added to the trench. Convenience causes these important points in numerous instances to be disregarded, but a due attention to their relative value would enable a planter of moderate experience to predict the comparative success or failure of removals, supposing in each case that the trees or shrubs were equally well planted, in their new position.—*E.*

Transplanting Forest Trees.—I observed in the *Chronicle* of March 30, a statement from a correspondent signing himself "E.," regarding the transplanting of large forest-trees, and expressing a wish for information respecting the preparation of them "before transplanting." As far as my experience goes, I would be inclined to give preference to trees prepared in July. The selection of the tree, however, for its situation, is of more importance to its future success than preparation. For instance, take a plantation that has stood for years pretty thick, cut out the greater part of the trees, leaving at distances of 60 or 70 yards two or three trees together; these trees, on being suddenly exposed, although not moved or touched at the roots, will become as stunted and ill-thriven as if they had been taken from the same situation and transplanted in any other, similar to the one referred to before the wood was thinned. This I know from experiment. "E." has given a statement of the expense of removing his trees, but has omitted to say how far he did remove them; consequently he has left us in the dark. I cannot agree in his tearing up the tree after clearing its roots of soil on the surface, for this among other reasons, that if the tree happened to have (as a good many of them have) a strong tap-root, before this is removed the force of tearing up the tree will necessarily shake away all the earth from the other roots, because of the resistance the tap-root offers to any force in any way applied to turn the tree over.—*Clouden.*

Dwarfed Fig-tree.—I have in my possession what I believe to be a unique curiosity in this country—a Banyan-tree, dwarfed in China, and known to be 200 years old! It was sent to me by a friend in India, and was traced back from one possessor to another in that country for the time above mentioned, having always been regarded as a great curiosity. It arrived, unfortunately, during a severe frost, two years ago, which affected it on its journey from London (having been exposed for one night to the open air), and one of its principal branches was frost-bitten to such a degree, as to make it necessary, in order to save the life of the tree, to have the branch cut down. The other remains perfect. I am aware that there are dwarfed Bannian-trees in other collections in the kingdom, but none, I am given to understand, of so small a size, and of so great an age. I am credibly informed that the Chinese have lost the art of dwarfing forest-trees in this peculiar manner. It has not been removed from the China vessel in which it came from India. Its height is only 2 feet, circumference of one stem 7 inches, of the other 11 inches. It is now in vigorous health, is kept in the hothouse in the winter, and put into the sun during the summer months, removing it at night. It requires very little water. It is a tree of great beauty, and its form is a perfect study for the artist.—*E. C.* [This is not a Banyan, but a curious specimen of Ficus nitida.]

Pine-Apples.—In reply to "A. B. C.," in a late number, I beg to mention that, in different places which I have lately visited, I have observed that the tank-system is not well adapted for the growth of the Pine apple in all its stages; it is better suited for the forcing of Melons, Cucumbers, Asparagus, &c. He states that his house is in three compartments, that the first is composed of wooden stages, and that the pots are suspended by their rims in the same; I imagine this would be the best compartment of the three for fruiting the plants in, more especially about the time he wanted them to fruit. By withdrawing the water from the dishes, having a gentle heat given out by the pipes alone, and at the same time giving little or none to the root, for a few weeks (the plants being strong, and the pots full of roots), would throw them into fruit. I am of opinion that the tank-system disappoints the generality of Pine-growers; many admit that by that system they can produce noble-looking plants, with fine foliage and healthy action, but this is at the expense of the fruit. I do not agree with a statement in Macintosh's "Practical Gardener," which says, "that Pines starting into fruit in August are tantamount to being lost;" as, in large establishments, gardeners are obliged to have a succession for the most part of the year; and of Pines—say a variety of Queens, Black Jamaica, and Montserrats, if strong, healthy plants—showing fruit in August, the Queens would ripen good fruit by the end of October, and the Jamaicas and Montserrats would come in in succession up to Christmas, and even much later; the two last are well known to be the best, both in point of swelling and flavour, for winter fruit. I would recommend "A. B. C." to put his strongest plants in that compartment having the stages, and, if practicable, to withdraw the water from the dishes, and likewise to discontinue watering at the root. The following plan I have often practised with success upon strong plants of shy bearing kinds, such as the Black Jamaica is allowed to be, viz.—with a pair of scissors cut off the tips of the leaves in the hearts of the plants, and continue to do so to others as they spring. This stops their over-luxuriant growth, and the change from excess of moisture to partial dryness, disposes them to fruit, when water might again be added if thought necessary. At all events, I should not discontinue moistening the pipes and pathways after every bright day, and the house should be shut up early in the afternoon.—*James Roberts.*

Pine-Apples.—Those who have the good fortune to reside near good peaty soil, need not be afraid of using it wholly in which to grow Pines. The plants that I fruited in all peat, swelled better during the winter months, and produced finer fruit than those planted in either rich soil or turfy loam. For plants that are to fruit in winter, peat is excellent, on account of its loose texture. Pines planted in a mixture of half charcoal and loam, have fruited very well. All sand gives no one cause of complaint; on the contrary, it should rather be recommended, for the roots become very strong in it, and the rootlets are much more numerous; indeed, I never saw roots so strong and numerous in any other substance. It is not of much importance what kind of material Pines are grown in, provided the roots are in a healthy active state, and free from sudden changes of bottom-heat. The soil in the pot should also be kept from becoming soured by allowing decaying bark to adhere to the outside of the pot. Keep out worms by placing the pot, when plunged, on a flat brick.—*W. Brown, Morpeth.*

Opposite Opinions, Rooks, &c.—The various, and in some instances contradictory statements, of your correspondents, must, in many minds, create a tendency to scepticism; that is to say, where parties do not make practical observations and judge for themselves. One states that salt has produced him magnificent Asparagus—another says that salt has destroyed his plants. One advises carcases as a manure for Vine borders—another says that has nearly destroyed his Vines. One says that for 30 years he has not suffered from Turnip fly, owing to his steeping his seed in oil, and powdering it with sulphur—another says he has tried it, and still the vermin have marched in military array over his field, perforating and consuming his crop. One says persecute the rook and other birds—another, encourage them as your best friends. As great a contrast frequently arises as to the quality of fruits—one stating a particular variety to be excellent—another will not admit it to be second rate. How are we to reconcile such statements, admitting, as we must, in respect of parties with whom we are unacquainted, that each is entitled to equal credit? In many instances, no doubt, the old aphorism may be applied—"Circumstances alter cases," as with regard to salt and carrion manure; a skilful gardener, knowing the time, and watching the result of his experiment, follows up a perceptible improvement, and counteracts the first appearance of a retrograde movement before the disaster becomes irremediable. In similar cases, the rash or inexperienced fail. With regard to the Turnip fly also, there may be some peculiarity of tillage. I have heard of a whole field failing except where a roller had casually been drawn—in some seasons, that the plants are more liable to attack when the ground is rolled. As to fruit, there can be not the least doubt that soil and aspect, or climate, will produce a much greater difference than exists between the first and second class. But with regard to the rook and birds generally, I think there ought to be but one opinion, namely, that their usefulness very greatly exceeds any injury committed by them, either to the farm or garden. An instance is recorded upwards of a century ago, I believe by Bradley, of the inhabitants of a certain village destroying the whole race of birds in their locality, by setting a price upon their heads; the consequence of which was, that their entire produce was attacked by insects and caterpillars innumerable the following year, and they were glad to offer a similar or greater reward to have fresh colonies brought in to their assistance. Dr. Stanley also relates that a whole district in Germany was nearly deprived of its corn harvest by having destroyed their rooks. I have myself seen a field of Swedish Turnips so infested by grubs, that from three to ten were found under nearly every root that was examined, the Turnips having the appearance of warty excrescences and quite hollow within. An immense flock of rooks, accompanied by a flock of starlings, covering more than an acre, alighted upon them, and so busy were they that they would allow a person to go within a few yards of them without flying up. They remained there a whole afternoon, and on examining the Turnips afterwards, I found scarcely one that had not been cleared of the grubs. That piece of ground has been much more productive from that time; and I think at least some share of the improvement is due to the rooks, though certainly not all. As to sparrows and other small birds, particularly wagtails, a careful observer may see them in breeding time following the plough or scarifier, dart their beaks into crevices and pick out the wire-worms incessantly, then carry them to a smooth piece of earth, lay them in a bundle, and then clasp them firmly in their beak and carry them off to their young. Now suppose the rook in searching for grubs pulls up the plant with it, would not the vermin have ruined it in all probability if he had not? And allowing that he pulls up some Potatoes on the moor lands, a little expense of watching obviates that calamity. Also allowing that sparrows will do considerable damage to the Wheat crop from the time the grain is formed until harvested—a period of six weeks or two months—wasting as much as they eat, yet a few old men, for a few shillings per week, may check their depredations over an extensive farm. But by what process, involving fifty times this outlay, could man himself perform the service rendered him by these active labourers, who never want calling to their employment—are never idle when there is any prospect of their working to advantage—who never call upon their protector on a Saturday night. Prejudices often take deep root, and are handed down from ancient to modern times; sparrow clubs are still in existence; and I was informed a few days ago of a person sending 3000 heads to a member of one club, and having to send 3000 more to be exhibited as the genuine trophies of that individual. He also may consider he is doing man a service; but unless I receive further evidence to the contrary, I must continue in the opinion that birds are eminently serviceable to man during at least ten months out of the twelve; that there is no known substitute for their services; and that any injury which they might effect during the rest of the year may be easily and cheaply prevented.—*F. J. Graham, Cranford.* [What a pity it is that people should not have sense enough to attend to these true and excellent suggestions!]

Moss on Gravel Walks.—I sometimes destroy Moss on walks in a very simple manner. It is continually when the surface of the walk is smooth and moist, that Moss abounds; winter is the time best suited for destroying it. By watching a certain degree of frost it will be observed that the surface of the walk, by the expansion of the ice,

will be somewhat loosened, and the Moss thrown out; I then sweep with a stiff broom, or scrape with a draw-hoe, and clean it up afterwards. If the frost is too slight the Moss will be but partially removed, and if too severe, too much of the surface will be loosened; but when a *proper* opportunity occurs, millions of plants may be destroyed in a short time, and the walks look much refreshed afterwards.—*Peter Mackenzie.*

Gravel Walks.—The following is an excellent plan to make (or turn over these in dry weather):—If of a sandy or gravelly nature, strew a little clay or marl upon the walk. When turned over, take away the large stones and place them at the bottom of the soil. Immediately after you level your walk, apply your iron roller steadily, and let a labourer follow the roller, pouring upon it water regularly as it passes over the ground; in 24 hours after, if the weather is dry, it will be as solid as a stone floor. The writer has had ocular demonstration of the fact in 20 instances, in the late dry weather.—*W. R. Hanwood, Liverpool.*

Conservatory Climbers and Fixed Roofs.—In pursuance of the advice given by Mr. Beaton, I had the only sliding sash of my conservatory fixed with screws; and in the hot air thus confined, several of the climbers have certainly flowered far more freely than before. Bignonia Cherere is now splendidly in bloom, as are Ipomœa Learii and Mandevilla suaveolens, which promises to bear a succession of its fine flowers through the autumn. Bignonia jasminoides is also producing its blossoms of almost peerless beauty in large masses; but several other plants do not seem to like the heat. I have several fine specimens of Kennedyas, Zichyas, and Hardenbergias, which, after reaching the top of the pilasters between the windows, are carried along the arches forming the support of the climbers; in this situation the leaves and branches have been quite burnt, and the same effect, though in a less degree, has been produced on Bignonia grandiflora, which, for the sake of its flowers, I still retain in the house, though, doubtless, perfectly hardy in this county. Will any one recommend me a few more climbers that will bear the temperature produced by the fixed roof, either to be planted in the border, or to be inarched on those now growing? Various fine Bignonias and Ipomœas I conceive might be introduced, and there are possibly some things that would unite with Mandevilla. I have lately added Bridgesia spicata, Brachysema villosum, and Beaumontia grandiflora; but the latter seems a slow-growing plant, and, I fear, will be some years old before it blooms. The Brachysema I understand is a fine thing, and will of course not attain the height of its stronger-growing companions.—*A Devonian.*

Longevity of a Pæony.—A plant of the double crimson Pæony is growing at a cottage-door, at Great Chesterford, in Essex, which is known to have occupied that identical spot 100 years. The grandfather and grandmother of the woman who now lives there were both born about 120 years ago, and could not remember the time when it was not there. It is not a very large plant, sending up 16 stalks.* That it lives by the permanency of the original tubers, and not by the formation of new ones, may be inferred from the identity and minuteness of the spot of ground, which it occupies without spreading. Is it ascertained that herbaceous perennials are of shorter life than the Oak or Chesnut?—*A. H.*

Stipa pennata.—It is not generally known that the seed of the Stipa pennata produces a flour very much like that of Rice; and, I have no doubt, on poor sandy soils, would produce a bread Corn, where scarcely anything else would grow.—*Anon.*

Tall Stock.—I have a stock which measures the great length of 2 feet 11¼ inches from the top of the bloom to the last seed-vessel; the stem was cut as close to the seed-vessel as possible.—*Mede.*

Village Horticultural Societies.—Your remarks on the necessity of showing in classes are perfectly true; but, except in the three classes of Gentlemen, Nurserymen, and Cottagers, I do not see any sufficiently broad distinction to make further classification practically useful. The Squire, with his head gardener, hot-houses, &c., will no doubt carry off many of the prizes, but the amateur will very often beat him with his Florist Flowers, Pelargoniums, Fuchsias, and those requiring only greenhouse, or frame; and the Tradesman will generally beat both with his Auriculas, Tulips, Pinks, or Pansies. I have taken the trouble to analyse the number of prizes gained at our last Exhibition, where subscribers all show against each other; and I have subdivided them into four classes:—

1. Gentlemen, with head gardener, hothouses, and every advantage.
2. Amateurs, with one gardener to assist them—mostly a common labourer.
3. Tradesmen, working their own gardens.
4. Market gardeners, who employ men under them.

Eight of the first class contributed 121 articles for exhibition, and obtained 32 prizes, (or about 1 in 4.)
Ten of the second class contributed 69 articles for exhibition, and obtained 14 prizes, (or about 1 in 5.)
Twelve of the third class contributed 98 articles for exhibition, and obtained 13 prizes, (or about 1 in 8.)
Three of the fourth class contributed 22 articles for exhibition, and obtained 7 prizes, (or about 1 in 3.)

You will see by the above that the disproportion is not very great between the Amateur and the Gentleman, and that the Tradesman obtained a greater proportion than either. In the Cottager's Class, 53 Cottagers contributed 137 articles, for which 32 prizes were distributed among 24 of them. This was in a country village, the population of which does not exceed 1200, but the Cottagers of all the neighbouring villages are allowed to compete.—*A Village Secretary.* [We think that in this instance the number of prizes which each exhibitor gained should not be lost sight of.

The Gentlemen obtained 4 prizes each.
Amateurs ,, 1 ⅛ ,,
Tradesmen ,, 1 ⅓ ,,
Market Gardeners 2 ⅔ ,,

This seems to give the Gentlemen a great preponderance.]

Spot on the Pelargonium.—I imagine that this arises from the effects of Green-fly. I, however, do not mean to assert that Green-fly alone produces the spot; but this, in combination with other circumstances, causes it. One of these is the want of paying attention to regularity of watering: when water is injudiciously or sparingly supplied, the result is a sickly and half-dead plant, full of spot and Green-fly. The Pelargonium requires to be regularly supplied with water when in a growing state; if the leaves are allowed to droop time after time, the cause will soon be shown by its effects. Immediately afterwards there appears upon the leaves a sort of sticky substance not unlike sugar, when dissolved and rubbed upon anything, which is injurious to the plant. In order to grow Pelargoniums to perfection, they should have a house wholly for themselves, which should be shaded with canvass, so as to exclude the mid-day sun. Air should be freely admitted, and the plants syringed every other night, when not in flower, with clean water; they should never be too much crowded together, but should be kept a good piece apart, so that air may circulate freely among them. By paying proper attention to these things there is no fear of the spot ever making its appearance. Particular attention should, however, be paid to having a free and open drainage, so that water may not stagnate about the roots. These rules I have seen practised with success in large establishments where hundreds of Pelargoniums were grown.—*Caledonia.*

Bees.—If (p. 405) "An Old Correspondent" had aroused his Bees by rapping on the under hive, instead of leaving them to ascend into the upper one of their own accord during night, most probably they would have done so, and thus prevented the others descending into the lower hive. In uniting Bees from established hives, a little smoke from the fungus Magus (?) is very useful; it makes them quite white, so that they may be handled like Peas. I question if "C.'s" exhumed Bees were "better off than his unnatural swarm" that attacked them; if otherwise, they would have kept them off. The plan adopted to save the "persecuted Bees" might be right; but attacked hives are in general too weak to be of much use, and frequently the pillage is too far gone before it is observed. Removing the Bees beyond the flight of the invaders may be right; but others might get scent and carry off the spoil. If the treasure be an object, the best way is to smoke the Bees from the besieged hive and take it. "C." imagines that some of his Bees were "idle" because they attacked their weak neighbours, but their good store speaks other things; the additional room, if the season admit, enables them to lay up more honey. I may mention that Bees are very fond of the Salvia nemorosa, or Wood Sage. Those who cultivate flowers for Bees ought to grow this plant in abundance.—*J. Wighton.*

Ants.—The best way I know of destroying an ant's nest is by Elder-leaf tea. Boil the leaves in water, and if the tea will injure the roots of any plants, the mixture will be found quite efficacious when cold. I have lately destroyed several nests this way. Elder-tea destroys the Aphis on fruit-trees, and most likely many other insects.—*C. A. A. Lloyd.*

Ants.—In Notices to Correspondents (p. 464) it is said, "We know of no effectual remedy for these troublesome little pests." Please take Cobbett's "English Gardener," and read paragraph 299.—*Paddy.*

Rats.—Observing communications in the *Chronicle* lately, relating to destroying rats, it appears to me the great desiderata in these matters are simplicity and easy application. I therefore make no apology for stating what I have experienced to be most effectual, and combining the two above-named properties:—For the destruction of rats—An ounce of white arsenic mixed up with 3 ounces of lard, spread on slices of bread, which cut in pieces longer than broad (say about 3 inches by 1 for the convenience of putting into the holes). In every rat-hole put a piece of bread and lard, taking care to put it well down the hole, so that dogs or poultry cannot reach it. By this means I have killed thousands of rats, and those not killed desert the premises for at least six months.—*F. G. C., Aston Hall, Hawarden.*

Swans.—A correspondent, "M., Deptford," at p. 390, makes some remarks on what I had said respecting swans.—"Without being pinioned, how are they to be kept, especially in small ponds?" He classes the operation of pinioning with that of "docking, horses, dogs, &c." I hope he does not imagine that I am an advocate for cruelty to animals, when it can be avoided. There are, I suspect, many operations performed on animals for useful and legitimate purposes, that are more cruel than the practice of pinioning swans. "M." observes that swans can be kept without this, because they "have strong local attachment." But he does not say how he contrived to overcome this local attachment in the "pair of swans, which he procured in their second year unmutilated." It would have been expected that upon the principle of local attachment, they would have returned to their former home. Be that as it may, I am persuaded that pinioning is the most effectual expedient for keeping swans at home, especially on small ponds; and their beauty on the water is very little impaired by it. Where swans are kept on large streams, and belong to different proprietors, to allow them to fly must lead to worse confusion than the plan in common practice. "M." speaks of dogs attacking swans that have been pinioned. It must be a powerful dog indeed that would attack a swan in the water. But, on the other hand, if swans could fly, they would be far more likely to fall a prey to the fowler. An instance of this occurred to my own knowledge, a few years ago, near the river Wensum. A swan, which had chanced to escape pinioning, took flight in the winter, and was shot. The person who shot it affirmed that he took it for a wild swan; which was certainly a very natural mistake. I fear the like would be of frequent occurrence, if swans had liberty to use their wings. They have a great dislike to any other fowls being in their waters—even to those of their own species. But it must be borne in mind that they are not gregarious, that is, the tame sort; for the wild swans visit us in flocks from the northern regions in winter. I cannot believe, with "M." that swans kill toads, through jealousy, at the breeding season; such jealousy is to me quite incomprehensible.—*J. Wighton.*

Brugmansia parviflora.—Some of our horticultural friends may, perhaps, be glad to be told, through the medium of the *Gardeners' Chronicle*, that the plant known in our stoves as Brugmansia parviflora, or B. floribunda, is a very different genus from Brugmansia, and one that no botanist seems to be acquainted with, since the days of Ruiz and Pavon. It is strange that it should have escaped the notice of cultivators that it is the Juanulloa parasitica of Ruiz and Pavon's Flora Peruviana, vol. ii. p. 47, tab. 185. It is a "parasite," or more properly an epiphyte, "on the branches of trees, near Pozuzo, and San Antonio de Playa grande in Peru."—*W. J. Hooker, Royal Botanic Gardens, Kew.*

Covering for Frames.—Having seen many statements in the *Chronicle* respecting the advantages derived from waterproof calico for greenhouses, &c., I beg to offer the following remarks, being an eye-witness to the results. Having a Vine situated against a brick wall, and being anxious, if possible, to ripen the fruit, I determined on erecting a shed over it, in every respect similar to a greenhouse, the dimensions of which are 13 feet long, 9 feet high, and 8 feet wide, with a fall of nearly 4 feet, and covering it with calico prepared with oil, wax, and acetate of lead. The sashes are moveable, so that I can at any time regulate the temperature. In many respects I consider this preferable to glass. In the first place the condensation at the top of the house at night is so much, that the Vine always has a sufficient degree of moisture; 2dly, the light is more agreeable, and the heat is retained much longer; and, 3rdly, when the foliage is rather scanty it so shades the fruit, that on the warmest day there is not the least danger of its being injured. This building I had only erected on June 3, just as the Vine commenced blossoming, and having another Vine exposed entirely, I have been able to remark the difference. The Vine inclosed has gained so much on the other, that persons who have seen it consider the thing almost impossible, the Grapes at the present time being nearly as forward as those which have been inclosed under glass all the winter, whilst those uncovered, against the same wall, have only just commenced swelling. One thing I would recommend to those who are disposed to give it a trial, is, to avoid its coming in contact with the leaves, as they are almost certain of being scorched. I mention this, because I have seen complaints made of the foliage being blistered. In using it for protecting fruit trees I would advise that instead of having it placed within 3 inches of the tree at the top, and 12 inches at the bottom, to have it erected at double that distance from the tree.—*J. A. Spargo, Totness, Devon.*

Whitney's Composition.—No sooner does a man like Mr. Whitney invent and bring forward to public notice an article to benefit or assist those who wish to cultivate a taste for Floriculture, than we all find fault with it, and try to make a similar article a little cheaper. Many thanks, however, are due to Mr. W. for starting the plan. So great is the difference in price between a frame glazed and one covered with varnished linen, that had the inventor stated the price of varnish at double what he did, most persons would have been contented. I have tried Whitney's Composition, and also the mixture of oil, resin, and dryers, which I find equally good. I fear that many will be disappointed in its general appearance after the first winter; the excrement from birds, dust, and small pieces from the Larch, &c., have already made my roof look unsightly. I would caution those commencing, to use linen instead of calico, and to strain it remarkably tight. I have been obliged to take the linen off 12 lights, after being twice varnished, and, as I thought, finished, on account of its being too loose; whilst in my propagating pit I might fancy myself on board ship, with the sails flapping above me. My frames are 6 feet long and 3 wide, with two divisions in the length and one across; I should, however, prefer three if I covered more frames.—*G. C.*—Another correspondent writes as follows:—Seeing so many complaints in the *Chronicle* about Whitney's Composition not going so far as is stated by him, I consider it but justice to mention the following facts:—Having had nine lights of a pit to cover, each 4 feet square, I procured two pint bottles of the Composition from Mr. Whitney himself, which gave the nine lights two coats nicely. The cloth was glazed calico, at 5*d.* per yard. About six weeks ago, I had a span-roofed pit erected, having 14 lights; each light was 4 feet 6 inches long, and 4 feet 2 inches wide; the cloth was strong linen, at 8*d.* per yard. For this, I bought two quart bottles (from one of Mr. Whitney's agents), but I found that each of the bottles wanted at least one-fourth of being full; consequently it did not go so far as the first, and

the cloth likewise being thicker, absorbed more of the liquid. A good deal depends upon the quality of the cloth. The two bottles would scarcely do nine lights; I therefore got two more quart bottles (from another agent, which were quite full); one of these finished the remaining five lights, and also three more, much better than the two quarts on the nine. I, however, committed an error in using the first pint bottle. Mr. Whitney directs that it should be applied quite hot; so in making it quite hot, I must have caused it to boil; but instead of becoming thinner, it formed quite a hard substance.—*A. Threlkeld, Headingley-house, Leeds.*

Whitney's Composition.—This will not be found to stand heavy wind and rain, unless the material is thicker than the calico recommended. A frame I had covered with it has been torn in pieces, and I find others make the same complaint. During the previously dry three months nothing could answer better.—*A. R. C.*

Fixing Ammonia.—Have you ever known soot tried for this purpose? My fuel consists altogether of dried peats, and the soot, I find, destroys the offensive vapours of a small urine tank.—*Paddy.* [No doubt soot, which is chiefly charcoal, will perfectly answer the purpose, if you can get it. We have often said so.]

Hard Water.—My pump raises water unfit for many domestic purposes; soap is curdled by it, and vessels in which it is boiled are coated over by a hard substance, of a light-brown colour. Leaden pipes are, in about ten years, reduced to a rotten state. Mixed with oxalic acid, the water assumes a milky appearance, and deposits a white sediment. Can any one say what would prevent the deposit on boilers or kettles, without injuring the water for use?—*Paddy.*

Cucumbers.—A market-gardener has failed in his ridged Cucumbers these three years past. This year they looked strong and healthy from the first, until about three weeks since, when they again showed symptoms of decay. They began to droop here and there; and on pulling up the affected plants, there were no wire-worms, nor anything else visible at the roots to indicate the cause of the stems dying off. Cucumbers have been grown upon the same ridge for several years, but of course, with fresh dung and mould; and the reason for using the same place so often is, that it is protected a little by a brick wall, about 3 feet high, at the north. The soil is good and deep, and although not drained, it is not very heavy or wet. The subsoil is clay or chalk.—*Hodge.* [The disease, as above described, is of frequent occurrence. It probably arises from a want of moisture at the roots.]

Chiswick Exhibition.—An error has crept into the report of the Exhibition of the 13th, which I cannot allow to pass unnoticed. It is stated that "Mr. Rowland also contributed Roses, but they were overblown; and the collection contained no remarkable kinds." This is a very great mistake; and I can positively assert that there was not one Rose overblown in the whole collection, which was at the time very much admired, particularly the Devoniensis, Smith's Yellow Noisette, Prince Albert, Luxembourg, Charles Duval, Adam, &c.; and for which collection the Large Silver Medal was awarded. So far from the Roses being overblown, the whole that were exhibited remained in the same boxes several days before one flower dropped, which can be testified by several Amateurs who happened to visit my garden.—*Alexander Rowland, F.H.S., Rosenthal, Lewisham.*

Ancient Charcoal.—Some time ago when a person was digging peat he came upon a quantity of charcoal; the peat was upwards of eight feet deep, and the charcoal was found about four feet from the surface. One naturally inquires how old it may be, and when the fire was kindled that charred the wood? Could it be by our naked ancestors, or those who came to conquer them? It is said that the Emperor Severus gave orders to cut all the forests in Scotland; or perhaps it was done by the followers of John Duke of Lancaster, when he set 24,000 axes to work to cut down the Caledonian woods. Not far from where the charcoal was found there is an embankment which goes by the name of the Roman Camp; and at the base of the hill upon which it is situated there is part of the line of an old Roman road. It is well known that Roman coins and Roman vessels are found in peat that is much deeper than four feet; but it is difficult to ascertain the age of peat by its thickness, for peat only two feet thick may be as old as that which is twelve feet thick; and we may not be very far wrong if we say that the age of the charcoal may be 1500 or 1600 years. I have sent you a small portion of it for your inspection; you will observe that it wants the jet-black appearance of well-made charcoal; this is perhaps owing to the colouring matter of the peat in which it had been so long soaked. [The charcoal had been prepared from Fir-wood.] Can it be ascertained by the Pine wood that is found in peat if it belongs to the same species that at present goes by the name of Scotch Fir, Pinus sylvestris? From the quantity of rosin that is obtained from the wood that is got in peat some imagine that it belongs to a different species. Some time ago a Pine trunk that was found in peat was cross cut, and exhibited rather an uncommon appearance when smoothed by the plane; there was seen five series of concentric circles, the largest series containing between 80 and 90 circles; they appear to be all perfectly united to each other, except at some places where traces of bark are seen; the diameter of the trunk measures in one way about 14 inches and the other 9 inches. May we suppose it to have been a stunted tree, or the seasons to have been warmer than they are now? The growth of 1826 can be easily pointed out in cut timber, being well known from the small quantity of wood it contains.—*Peter Mackenzie.* [All we can say, after the examination of the charcoal, is that it has been procured from Fir-wood, but whether it was Pinus sylvestris or not is uncertain. We do not perceive any difference.]

Water Colour from the Cactus.—(See p. 247, 1844.)—The Opuntia, whose juice is used for painting in Sicily, has long been known for that purpose at Naples. It is not vulgaris, humilis, Ficus indica, Amyclea, or, in short, what is commonly called the Prickly Pear, but a scarce and more tender species, which I have never seen in any English collection of Cacti. It is Opuntia Tuna, a fine plant, a great bearer of yellow flowers and a fruit of the richest carmine, not purple.—*W. F. S.*

Vegetable Dyes.—The roots of the Epine Vinette, which I take to be the common Berberry, is used in large quantities in France and Germany by the dyers, who extract from it a most brilliant green. The expense of transit, together with the difficulty of obtaining it fresh, prevents its use here; but the price which our dyers could give for it (from 10*s.* to 16*s.* per cwt.), might induce proprietors of large plantations to cultivate it as underwood. Would not the root of the Berberis aquifolium answer equally well?—*J. G., Tulse Hill.* [Common Berberry is the best.]

Ice-houses.—"A. E. W." wrote, in No. 8, *Gardeners' Chronicle*, that a Virginian, with some poles and straw, will construct an ice-house for 10 dollars as good, if not better, than those which cost our men of taste as many scores of pounds. Cobbett, of old, wrote to the same effect, and promised to give the full particulars, so that any countryman should be able to erect it, for the benefit and luxury of himself and his village neighbours; but I believe Cobbett never fulfilled that promise. Is there not among your readers a good-hearted Virginian that will give us this desirable information, in such a clear manner that we could work thereby with a fair prospect of success?—the first consideration being economy in cost. A person having an unused Mushroom-house, on a retentive soil, would, I fancy, find himself much disappointed if he adopted the recommendation of "A. E. W.," without putting in some drains to get rid of the water as it sinks into the broken-up earth; and if "A. E. W." be successful, it more than likely arises from his house being on a gravelly subsoil, which forms a natural and perfect drain.—*H. S.*

Morphology.—The interesting articles on Morphology that appear, from time to time, in the *Chronicle* will induce people to look more attentively at vegetation than they were formerly accustomed to do; even those who had a little "smattering" of botany will look upon their old acquaintance in a new aspect. In a Scotch Fir-tree we commonly find a centre shoot and five or six side ones; but, where a cone is produced, there is a shoot deficient, there being only four or five side ones. I found, what I considered to be a remarkable coincidence, between the pips of the cone and the leaves of the side-shoots; the number of pips was 62, and the number of pairs of leaves on a shoot beside the cone was 64. Is this an instance of leaves being turned into fruit, or seed-vessels? The male blossoms of the same plant are commonly on weak shoots, which have not half the quantity of leaves on them that the more healthy shoots have. I found 30 pairs of leaves on those that I examined, and 20 bundles of male blossom, with 10 or 12 pairs of leaves above them, on the same shoot.—*Peter Mackenzie.*

Vegetable Phenomenon.—I beg to relate a circumstance which occurred to a Pelargonium. One of these plants, on which no flower had then opened, had been with others placed in an airy hall; the expansion of this occurred on the morning of the 6th day, when I was surprised at its altered appearance, every petal having become white and transparent as the clearest gauze, with the exception of a border of the colouring matter the sixteenth of an inch wide; the three lower petals were of a pale pink; the two others of a deeper colour; every blossom in succession did the same, and by constant inspection I found the transparency of each remained about five days; after which, in the same succession, the colour of all was restored with the freshness of newly-opened flowers. The case being so extraordinary it had my particular attention, which enables me to say you may strictly rely on my statement. My son not being at home during this time I dried some for his inspection, and this brought back the colour. This plant, I assure you, was the wonder and admiration of the many who saw it; particular care was taken of this plant, which I desired should remain untouched till the following summer, but no more of these changes have appeared since.—*E. B. Paington.*

Curious Growth of a Scotch Fir.—In the *Chronicle*, p. 574, 1842, there is a notice of a Scotch Fir-tree whose growth was somewhat remarkable; this year it is still more so. The leading shoot, and also the side shoots, started in the spring to all appearance like their neighbours, and continued to grow as on other trees of the same kind until the leader was about 4 inches long; when the side buds on the top, instead of remaining buds until the next spring, grew into branches. A leading shoot was again formed, which grew about 6 inches more, when the side buds a third time grew into branches, which are at present about 2 inches long.—*Peter Mackenzie.*

Myrtles.—Two years since I planted in my shrubbery two broad-leaved Myrtles. They face the east, and my house stands on one of the highest summits of the Chiltern Hills, South Bucks; they have stood the two last winters without any shelter or covering. A severe frost late in the last spring destroyed most of the leaves on one of them, but it has renewed its foliage and is healthy.—*J. Peers.*

Asparagus.—I have half a dozen beds of Asparagus, two years old, from seed; they were sowed in rows one foot apart, and the seeds set one foot apart in the rows: there has not been a single failure. I have given salt in pretty large quantity, and the plants are very strong, each root having five or six shoots. I fancy I should take out every other plant in the rows, leaving each two feet apart; before I do this I should be glad of your opinion, and if you confirm my idea, whether I should do it now or next season, a reply in the *Chronicle* will oblige your subscriber. [We should not disturb the roots. If the beds are well manured, the plants are not too many.] I think I have fairly tried salt, for the beds on which I have used it, now in the second year from sowing, produce from each root five to seven shoots; whilst those sowed with the same seed, at the same time, and side by side, are generally weaker in growth, and put forth two to three shoots only.—*J. G. B.*

Manures.—*Hibernicus* states that last year (spring of 1843) he manured three beds, each containing about 150 plants of Myatt's (Pine Strawberry); 1, with nitrate of soda; 2, with guano; and 3, with bone-dust. He remarked no difference in produce last year; but this year, the one to which the bone-dust was applied is much the best.

Foreign Correspondence.

Canton, Feb. 17, 1844.—The Chinese here are now making great preparations for the celebration of their new year, which takes place to morrow. Flowers of all kinds are in great request amongst the inhabitants, who employ them in the decoration of their dwelling-houses and temples. In going up the river towards the Fatee Gardens, I met boats in great numbers loaded with the branches of Peach and Plum-trees in bloom, Enkianthus quinqueflora, Camellias, Cockscombs, Magnolias, and various other things which flower at this season. The Enkianthus is brought down from the hills with the buds just expanding; and after being placed in water for a day or two, the flowers come out as healthy and fresh as if the branches had not been removed from the parent tree. This plant is a great favourite amongst the Chinese. The common Jonquil too comes in for a most extensive share of patronage; and in the streets of Canton one meets with thousands of bulbs growing in small pans amongst water and a few white stones. In this case the Chinese exhibit their peculiar propensity for dwarf and monstrous growth, by planting the bulbs upside down, and making the plants and flowers assume curious twisted forms, which are most agreeable to the eyes of a Chinaman. Large quantities of all these flowers are exposed for sale in many of the shops and in the corners of the streets in Canton, where they seem to be eagerly bought up by the Chinese, who consider them quite indispensable at this particular season. Not only are the houses and temples decorated, but the boats on the river also come in for a most extensive share. Indeed, these boats are only floating houses; for, as you know, a very great part of the population of Canton lives upon the river. The flower-boats, as they are commonly called, are particularly gay at New-year time with flowers of all hues, and gaudy flags streaming from their mast and stern. The crackers, or fireworks, of which the Chinaman is so fond, are let off in large quantities for several days in all parts of the town, and form part of their religious ceremonies or offerings to their gods. Their shops are closed on New-year's day, and for two or three days afterwards. The greater part of the natives have now on their holiday-clothes, and tramp about amongst their relations and friends to chin-chin them, and wish them a happy new-year, as we do at home. Large parties are made at this season to go up to the gardens at Fatee; and on particular days, you find there hundreds of these flower-boats crowded with well-dressed young Chinese, enjoying themselves as our own population do at Richmond or Hampton Court at home. This is the only season when well-dressed ladies are visible at Canton, as they now go over to Fatee in the flower-boats, and walk about in the gardens.—*R. F.*

Societies.

ROYAL SOUTH LONDON FLORICULTURAL SOCIETY.

THIS, the THIRD MEETING for the season, was held in the Surrey Zoological Gardens. The weather was favourable for the occasion, and the Exhibition was, in many respects, superior to the former meeting.—The MISCELLANEOUS COLLECTIONS OF PLANTS shown by *Amateurs* were deficient; but those produced by Gentlemen's Gardeners and Nurserymen were highly creditable. The best collection in the gardens was from Mr. Bruce, gr. to B. Miller, Esq., and comprised, among others, Achimenes longiflora and grandiflora, finely managed; Hoya carnosa, twining gracefully round a wire trellis; Siphocampylus betulifolius, flowering abundantly, and in excellent health; a good Clerodendron squamatum, and a pretty Euphorbia splendens, together with Pentas carnea, and several well-grown Heaths.—Mr. Atlee and Mr. Hamp also showed as Gentlemen's Gardeners, the former producing, among others, a very large plant of Erica intermedia, a tolerably-good Manettia cordata, but scarce of bloom; Hoya carnosa, and the useful Gardenia radicans, together with Burtonia conferta, Erica ampullacea, and Savileana, loaded with blossoms.—Mr. Hamp received a Large Silver Medal for a group containing the free-flowering Erica mutabilis, Clerodendron squamatum, a pot of Achimenes grandiflora, and a large Ipomœa.—In the *Nurserymen's Class* there were three exhibitors, viz. Mr. Jackson, Mr. Fairbairn, and Mr. Bushell. The group by Mr. Jackson was the best, and was awarded a Gold Medal. It included, among others, good plants of Statice incana, sinuata, and Dinkensoni;

Hibiscus Cameroni, and a considerable number of Heaths, among which was an excellent Hartnelli, in luxuriant growth, its branches hanging over the pot, and feathered with healthy foliage; a magnificent bush of Jacksoni, and a good Westphalingia, quite a mass of bloom.—Mr. Fairbairn obtained a Large Silver Medal for Lilium eximium, having ten fully-expanded blossoms; a purple Petunia, named Beauty; some Fuchsias, and several young, but finely-managed Heaths.—Mr. Schroder and Mr. Cox showed in the Amateurs' Class, the former bringing the best plants, among which was a good Erica Irbyana; Boronia viminea, with small pink blossoms; Mimulus Fraseri, a pretty dark variety; Martynia fragrans, and a yellow Thunbergia, called Fraseri.—From Mr. Cox was Aphimenes longiflora and grandiflora; Eucomis punctata, producing four spikes of green-coloured blossoms; a Gloxinia, and a plant of Lilium punctatum speciosum. Of Heaths there were two Collections present, one from Mr. Fairbairn, of Clapham, the other from Mr. Jackson, of Kingston. Of the two, that by Mr. Fairbairn was the best; it contained good plants of ampullacea vitata, a variety of ampullacea called s. nana; Savileana, in a lovely state; Jasminiflora alba, in fine health; and a dwarf, bushy plant of eximia, loaded with bloom.—From Mr. Jackson was tricolor superba, an excellent variety; cerinthoides, with brilliant scarlet blossoms; the free-flowering Savileana, a pretty Jasminiflora alba, a large princeps carnea, and a good eximia. Some Orchideæ were present, but among them there was nothing novel or particularly fine.—Mr. Don, gr. to G. F. Cox, Esq., received the First Prize, for Cattleya Harrisoni exhibited as a single specimen; and also for a Collection containing Miltonia spectabilis, Cycnoches chlorochilum, Broughtonia sanguinea, and Catasetum Russellianum.—A second group was from J. H. Schroder, Esq., in which were Vanda Roxburghi and Peristeria pendula, in fair condition.—The Second Prize, for the best single specimen, was awarded to Mr. Cuthill, for Lisianthus Russellianus, which had 18 stems, and was two years and four months old.—A well-grown Lisianthus Russellianus, finely in bloom, was also exhibited by Mr. Kay, gr. to B. D. Colvin, Esq., who likewise showed a tall Humea elegans, Maheruia incisa, Myoporum parvifolium, with white star-like blossoms, and some others.—Mr. Bruce was awarded a Large Silver Medal, for the best specimen plants of six distinct genera, among which was a fine Leschenaultia formosa, and a beautiful small Gardoquia' Hookeri.—From Mr. Jennings, of South Lambeth, were Erica mammosa, Lotus Jacobæus, and some Fuchsias.—Among miscellaneous objects was a Collection of Cockscombs from Mr. Suorer; well-managed Balsams from Mr. Atterton; 7 good plants of Lisianthus Russellianus from Mr. Cuthill; a group of Cacti from Mr. Schroder; and a box of cut Indigenous Plants from Mr. Turner.—Of Cut Roses, there was a good display; bunches of 12 varieties were shown by Mr. Edmonds, Mr. Parsons, and Mr. Paul, and good boxes of Cut Flowers were sent by Mr. Garty and Mr. Bruce.

The show of Picotees and Carnations was upon an extensive scale, the number of competitors being very numerous, and the flowers in excellent condition. The tent devoted to this part of the Exhibition was crowded during the day, and the display of these beautiful flowers appeared to afford universal gratification. The Silver Cup, offered by Mr. J. Dickson for 12 white ground Picotees, to be contested for among the amateur members of the Society, was awarded to T. Barnard, Esq., for a remarkably fine stand of flowers, consisting of the following sorts:—Ely's Great Western, Sharp's Duke of Wellington, Ely's Favourite, Brinkler's Lady Emily, Wain's Victoria, Wildman's Isabella, Burrough's Lady Downe, Sharp's Gem, Green's Queen Victoria, Jessop's Sir W. Middleton, Wilson's Pluperfect, and Barnard's Mrs. Barnard.—To *Amateurs*, Members of the Society, the *Gold Medal* was awarded to Mr. Edmonds, for 12 blooms of white ground Picotees. This stand, which was very fine, consisted of Willmer's Princess Royal, Nulli secundus, Jessop's Sir W. Middleton, Orson's Adelaide, Green's Queen, Barraud's Cornelius, Ely's Grace Darling, Headley's Nannette, Gidden's Princess Royal and Tanzer, Cook's Queen Victoria, and Brinkler's Purple Perfection.—*Large Silver Medal*, to the Rev. A. H. Matthews, who showed Dickson's Trip to Cambridge, Cook's Queen Victoria, Lady Alice Peel, Seedling, Enchantress, Ne plus Ultra, and Regina (seedlings also); Brinkler's Purple Perfection, Nulli Secundus, La Elegante, Sir R. Peel, and Lady de Grey.—*Middle Silver Medal* was awarded to — Proctor, jun., Bermondsey; to this collection no names were attached.—*Small Silver Medal*, to Mr. George Leach, for Burrough's Mrs. Bevan, Wilson's Pluperfect, Wain's Queen Victoria, Masson's Charlotte, Wilson's Harry, Willmer's Princess Royal, Barraud's Cornelius, Burrough's Lady Flower, Cook's Queen Victoria, Princess Augusta of Cambridge, Lady Payne, Miss Desborough.—For the best 12 blooms of Carnations, *the Large Silver Medal* was awarded to R. Headley, Esq.—no names attached. 2d, to Mr. Trevors, jun., *the Middle Silver Medal*—no names attached.—For Heartsease in stands of 24 varieties, *Middle Silver Medal*, Mr. J. Hunt; *Small Silver do.*, Mr. W. Hall.—Among *Gentlemen's Gardeners*, for 12 blooms of Carnations, *the Middle Silver Medal* was awarded to Mr. Embleton, gr. to T. Barnard, Esq. This stand contained the following varieties:—Dutton's Lancashire Lass, Hale's Prince Albert, Wilson's Harriet, Queen of Sheba, Greig's Mary, Barnard's Duke of Roxburgh, Martin's President, Red Rambert, Lord Pollington, Ely's Lady Ely, Willmer's Conquering Hero, Prince of Wales, Duke of Northumberland, Hufton's Lord Wellington, Addenbrook's Lydia, Puxley's Prince Albert, Sharp's Duke of York, Wilson's Harriet, Hepworth's True Briton, Brown's Dr. Watts, Brook's Flora's Garland, and Squire Meynell.—2d. *Middle Silver Medal*.—Mr. Norman, of Woolwich, for Wilson's Harriet, Hale's Prince Albert, Holmes's Count Paulina, Wigg's Earl of Leicester, Ely's Hugo Meynell, Mitchell's Patriot, Brook's Flora's Garland, Sharp's Defiance, Mausley's Bonny Bess, Roi du Capucin, Norman's B, and Low's Grand Sultan.—3d. *Small Silver Medal*.—Mr. Bates, of Oxford, for Wilson's Harriet, Hale's Prince Albert, Nix, Lord Chetwynd, Addenbrook's Lydia, Calcott's Brutus, Jones's Brilliant, Ely's Lady Ely, Hepworth's True Briton, Young's Earl Grey, Martin's Splendid, Toon's Prince Albert, Gregory's Alfred.—For the best 12 blooms of white ground Picotees. 1st Prize. *Large Silver Medal* to Mr. Willmer, of Sunbury, whose stand contained Willmer's Princess Royal, Gidden's Vespasian, Wildman's Isabella, Nulli Secundus, Willmer's Queen Adelaide, Sharp's Wellington, Wilson's Fanny Irby, Gidden's Miss Hennell, Jessop's Sir W. Middleton, Gidden's Teaser, Barraud's Bordene, and Hupton's Charlotte.—The *Middle Silver Medal* to Mr. Keynes, of Salisbury, for Gidden's Miss Hennell, Wain's Victoria, Sharp's Hector, Orson's Adelaide, Cook's Victoria, Wildman's Isabella, Hupton's Charlotte, Barraud's Cornelius, Wilson's Pluperfect, Green's Queen, Nulli Secundus, and Sharp's Wellington.—For Heartsease, in stands of 36 varieties, Mr. Brown, of Slough—the *Middle Silver Medal*. This stand contained Hannibal, Viceroy, Hale's Dark, Maid of the Mill, Orlando, Bella, Fair Maid, Warrior, Eclipse, Enchantress, Mulberry Superb, Duke of Beaufort, Cotherstone, Attila, Black Prince, William Tell, Chevalier, Alicia, The Prior, Plenipo, Venus, Duchess of Richmond, and 14 seedlings. Mr. Brown also exhibited a stand of 18 varieties of Dahlias, in very fine condition:—The Beauty of the Plain, Brown's Blue Bonnet, Standard of Perfection, Essex Triumph, Brown's Lady St. Maur, Sir R. Sale, Miranda, Springfield Rival, Dodd's Prince of Wales, Perpetual Grand, Bedford Surprise, Mrs. Shelley, Rembrandt, Brown's Delight, Indispensable, Phœnix, Union, Tournament, and Queen of the Isles.

Seedling.—For the best white ground Picotee, the *Small Silver Medal* was voted to the Rev. A. H. Matthews, for a seedling named Enchantress; and a similar reward to Mr. Norman, of Woolwich, for the best seedling Carnation. Seedling Heartsease recommended for a Prize, from Mr. G. King.

Of Fruit, among *Gentlemen's Gardeners* for the best collection of four sorts, the *Large Silver Medal* was awarded to Mr. Hamp, who also obtained the first prize for Grapes.—The award for the four best sorts in the Nurserymen's class, was given to Mr. Bursill, and Mr. Chapman obtained a *Middle Silver Medal* for good specimens of Black Hamburgh Grapes. Of Vegetables the best were shown by Mr. Gaines, and Mr. Atterton.

Reviews.

The Scientific Phenomena of Domestic Life. By C. F. Gower, Esq. 12mo. Ridgway.

The plan of this trifle is excellent. The Author explains, in familiar language, the true causes of the common phenomena that meet us at every step, and are therefore overlooked. If written by men acquainted with the subject, such books are invaluable, and that Mr. Gower is well acquainted with them, the following extract will abundantly show:—

"The current of air and smoke which ascends the chimney, is again an object to attract our attention—caused by the same expansive power of heat. The air, as it passes through and over the fire, becomes greatly increased in bulk, and consequently lighter; that is, a gallon of air expanded to double its bulk, or two gallons, will weigh only as much as it did before it was so increased, which causes it to ascend through the denser part, leaving its space to be filled by cold air from the door or window. By this means the fire is supplied with the proportion of fresh air necessary for combustion, whilst a considerable quantity of rarified air ascends the chimney, carrying up with it the smoke or dense vapour which arises from burning bodies.

"It may be inquired how it is that, when a fire is lighted in a room, the air does not descend the chimney to supply it, because that appears the easiest access to the outside air; and this, if the chimney were very large and quite open above, so as to admit space enough for an ascending and descending current, might be the case. To obviate this, if the chimney is large, we contract the opening at top, by putting on a chimney-pot, by which means the current of ascending air is rendered so strong through the small aperture as to prevent the external air from entering. We are very frequently disturbed by smoke coming into our rooms, particularly at first lighting a fire, and more especially when other fires in the house have been burning some time previously. When this is the case it will occasion a downward current of air in the chimney, caused by the other fires requiring a supply of air; and the open chimney being the easiest way by which the air can find admittance, this occasions the chimney to smoke when the fire is first lighted; but if the door of the room is closed and a slight portion of the window opened, the room is cut off from communication with the other fires, and the smoke will then ascend the chimney. When the fire is sufficiently established to cause a good draft, the window may be again closed, and the door opened without further annoyance, because the air to feed the other fires in the house will no longer find this chimney the easiest way of introduction, and some other means of entrance will probably soon discover itself. Sudden gusts of wind are apt to cause chimneys to smoke, by removing the equality of the atmospheric pressure on the outside, whilst the interior pressure is not exactly subject to the same influence. During the gust, the perpendicular pressure of the atmosphere above is partly removed by the velocity with which it passes over, in the same manner that the pressure or weight of a cannon-ball is removed from the earth while it is flying along, its velocity having overcome its gravity or weight; but when it loses its velocity, its weight again becomes perceptible, and it falls to the ground; the consequence is, that during the time of the gust, whilst the pressure is removed, there is a rapid draft up the chimney, caused by the want of resistance above; but the moment the wind lulls again, this pressure returns, the upward draft is suddenly checked, which causes a momentary obstacle to the ascending current, and a puff of smoke in the room is the most probable result. Some particular direction of wind will generally influence a chimney in this way more than another, either from some peculiarity in the situation of the chimney above, or from the apartment being more or less immediately influenced by the same cause; for, it is clear, if the variation of pressure above and in the room is simultaneous, no confusion will take place, but if the one happens a few seconds after the other, a contrary effect will be produced."

We heartily commend this little work to all our young friends.

NOTICES of NEW PLANTS WHICH are EITHER USEFUL OR ORNAMENTAL.

Lælia majalis. The May-flower Lælia. (*Stove Epiphyte.*) Orchidaceæ. Gynandria Monandria.—The history of this charming plant is so well given by Mr. Bateman, that we beg to extract it from his magnificent work on the Orchidaceæ of Mexico and Guatemala. "This lovely plant abounds in the most temperate parts of Mexico, where its exquisite beauty has rendered it a prime favourite with the natives, from whom it has received the familiar appellation of 'Flor de Mayo.' It does not, however, appear to have been long known to botanists, Dr. Schiede having been the first to send specimens to Europe, which, through the liberality of Professor Schlechtendahl have been extensively distributed. Living plants were first obtained by Mr. Barker, from Oaxaca, through the instrumentality of Mr. Ross: and more recently, a large supply has been received by the Horticultural Society of London, collected by Mr. Hartweg in San Bartolo, in situations so elevated, that the temperature sometimes falls below the freezing point. This habitat, so unusual for an Orchidaceous plant, will go far to explain the ill success that has hitherto attended its cultivation, for while it is comparatively easy to imitate the close and humid atmosphere in which most of the tribe are found, it is infinitely more difficult to provide a substitute for the pure air and frequent changes of temperature in which these mountain epiphytes would seem to delight. Instead, so signal, in the case of Lælia majalis, has been the failure of even the most experienced cultivators, that although there was scarce a collection that did not contain one or more specimens of the plant, still did it obstinately refuse to flower, except in the solitary instance about to be described, when it yielded to the skilful treatment of Mr. Dillwyn Llewelyn, of Penllergare, who has favoured us with the following note:—'This plant was purchased,' says Mr. Llewelyn, 'about three years since from M. Beschamps, and soon afterwards potted in very rough fibrous peat, being kept nearly dry in a cool plant house, until its new buds began to swell, when it was removed to a hot and damp stove, kept exclusively for Orchidaceæ. Water was regularly given until its buds had acquired their full size, when it was discontinued by degrees, and the plant carried back to a lower temperature. This treatment has been repeated, and under it the entire genus seems to thrive, although, perhaps, from the vigour of some specimens of L. anceps and L. autumnalis, which I have attached to pieces of rough barked wood (with a little peat tied round the root), I should prefer that course of treatment to the more usual one of potting them.' The mode pursued by Mr. Llewelyn is certainly the only one under which success can be expected; but there is yet a point to be gained, for while the specimens at Penllergare, however beautiful, consisted of only a solitary flower, in a wild state, three or four are borne upon a spike." The method of managing the plant in the Gardens of the Horticultural Society is as follows:—It is tied to a block of wood and suspended to a rafter in a moist stove. When removed from one block to another, which is sometimes necessary, it will be found beneficial to place a slice of turfy peat or a small quantity of sphagnum between the wood and the roots of the plant; this retains moisture in summer, so that less syringing is required. The quantity of water necessary for it on the bare block of wood would prove injurious to plants in pots below it. In the growing season the temperature does not exceed 80° by day, nor does it fall below 70° at night. In winter 56° with fire-heat is quite sufficient.—*Botanical Register.*

Miscellaneous.

Myrrh and Frankincense.—Major Harris describes the Myrrh-tree (Balsamodendron Myrrha) as growing abundantly on the Abyssinian coast of the Red Sea to the Straits of Bab el Mandeb, over all the barren hill-sides of the low zone inhabited by the Danakil or Adaiel tribes. It is called Kurbeta, and there exist two varieties; one producing the better description of the gum being a dwarf shrub, with deeply serrated crisp leaves of a dull green; while the other, which yields a substance more like balm than myrrh, attains a height of ten feet, and has bright,

shining, slightly-dentated leaves. The myrrh, called Hofali, flows freely from any wound, in the form of a milky juice, possessing a perceptible acidity, which either evaporates or becomes chemically changed during the formation of the gum. The seasons for collecting it are in January, when the buds appear after the first rain; and in March, when the seeds are ripe. Every peasant by transfers such portions of it as he may find to the hollow boss of his shield, and exchanges it for a handful of Tobacco with the next slave-dealer whom he meets on the caravan-route. The merchants also of the sea-coast, before returning from Abyssinia, send into the forests that gird the western bank of the river Hawash, and bring away considerable quantities of the Hofali, which is sold at a high price. The natives administer it to their horses in cases of fatigue and exhaustion. The shrub which produces the balm of Mecca (Balsamodendron Opobalsamum), is found on the opposite Arabian coast at Cape Aden, where it is called Beshán, either the original of or a derivative from the word Balsam. It is the Balessan of Bruce, who did not meet with the true Myrrh-tree. The balm flows copiously from any incision, and the ethereal oil speedily evaporating, a tasteless gum remains. The Frankincense, Major Harris states, is found chiefly along the Somauli coast, in the neighbourhood of Cape Guardafui. At Bunder Maryah, 20 miles to the S.W. of Ras Feeluk, the mountains are three miles from the shore, and attain a height of 5000 feet. Ascending 1000 feet, a plain presents itself, bounded on every side by precipitous mountains, studded with the Frankincense and Gum-Acacia-trees, although looking bare, from the total absence of underwood. The Frankincense-trees invariably grow from the bare and smooth sides of the white marble rocks, or from isolated blocks of the same scattered over the plain, without any soil whatever. From the base of the trunk, and about treble its diameter, a round thick substance is thrown out, of a nature between bark and wood, adhering most firmly to the stone, and resembling at a distance a mixture of mortar and lime. The stem rises from the centre of this mass, and having first taken a bend outwards of several inches, rises straight to a height of 40 feet. It throws out from the top short branches covered with a very bright green foliage, the leaves being narrow and rounded at the end, five or six inches in length by one broad, and crimped like the frill of a shirt, or rather like the sea-weed called by children on the English coast "the old gentleman's ruffles." The usual girth of the stem is from a foot to eighteen inches. The bark is perfectly smooth and consists of four distinct layers, the outermost of which is very thin; the two next of a singularly fine texture, resembling oiled letter-paper, perfectly transparent, of a beautiful amber colour, and used by the Somaulis to write upon; and the innermost about an inch thick, of a dull reddish hue, tough, and not unlike leather, but yielding a strong aromatic perfume. The wood is white and soft. On making a deep incision into the inner rind, the gum exudes profusely, of the colour and consistence of milk, but hardening into a mass by exposure to the air. The young trees produce the best and most valuable gum, the older merely yielding a clear, glutinous fluid resembling copal varnish, and exhaling a strong resinous odour. During the S.W. monsoon the pastoral tribes in the neighbourhood of Ras Feeluk collect large quantities of frankincense, which they barter with the Indian Banyans, of whom a few reside at the villages along the Abyssinian coast. Boats from Maculla, and from other parts of the Arabian coast also, come across during the fine season, and carry away the gums that have been accumulated, in exchange for a coarse kind of cotton cloth which is worn by the shepherds.—*Annals of Natural History.*

Horticulture of Auckland in New Zealand.—No country in the world seems to be better adapted to Horticulture than New Zealand: the alternations of shower and sunshine that characterise the climate for a great part of the year, cause a most surprising vegetation. All the common fruits and vegetables of Europe flourish in great perfection, and some of the southern climates grow vigorously in the open air. *Fruits.*—There are planted at present in this district, Peaches, Nectarines, Apricots, Almonds, Figs, Lemons, Oranges, Olives, Vines, Plums, Cherries, Mulberries, Pears, Apples, Quinces, Walnuts, Filberts, and the Loquat (Mespilus Japonica). These are all in a healthy state, and many give promise of fruit this season. It is doubtful if the Orange will ripen its fruit, or the Olive, both of which however are in a thriving condition. The Vine plants brought from Sydney in October, 1840, have already produced Grapes, and others procured from different sources, and planted subsequently in gardens, have thriven surprisingly. The cultivation of the Vine on a large scale is a subject that might be enlarged upon, but as it is expensive, and the return tardy, it is not likely to be attended to in the infancy of a colony, but it should not be lost sight of, and it is to be hoped that some enterprising and competent person may yet undertake it, for there can be no doubt that the volcanic lands in this vicinity are well adapted for vineyards, and that good wine might be made from their produce. The Gooseberry, red and black Currant, have been planted, but it is probable that the climate of this district is not adapted to them, as a long continued high temperature would seem to be unsuited to their habits; being natives of northern climates, they do not thrive, but probably means may be found to cultivate these national fruits. The same may be said of the Raspberry, unless planted in a very moist and shady situation. The Strawberry has afforded fine crops in some gardens, but the soil in general appears unsuitable: they generally run too much to leaf. The Cape Gooseberry (physalis edulis) is indigenous, growing wild in every part of the country, but if cultivated in gardens and freshly-turned ground in a greater size, and prove a valuable fruit for domestic purposes. It bears nearly throughout the year. Melons of several varieties have been grown in the open air, though late in coming to maturity, they were of delicious flavour. *Culinary Vegetables.*—The common culinary vegetables of Europe grow in this district in a manner that cannot be surpassed, but much judgment is required in selecting the period for sowing and planting. It may be stated as a general rule, that no seed need be planted in the months of January and February, as the dryness of the season and the attacks of the insects will render the labour futile. The results of the experience of three years are now furnished. Beans may be sown in May and June; when a foot high, it is best to cut them down close to the ground; they will then flower in September, and produce plentifully; if again cut down, they will bear again; they seem to be biennial in this climate. Kidney Beans may be sown from September to November: they bear plentifully, and a species (haricot blanc of the French) produces abundantly, and might be used in their dried state with advantage, as in the south of Europe, in soups and stews: they are very nourishing and palatable. The scarlet runner does not generally succeed well, but a species, the Lima pole Bean, introduced from South America, grows well in a rich soil and in a sheltered situation, and is a very delicious vegetable, being used as the broad bean. Carrots may be sown from April to September, but not later; they grow to a very large size. The Potato Onion, which thrives admirably, ought to be planted in June. A species of Eschalot, which has almost become indigenous, being cultivated largely by the natives, grows throughout the year. *Flowers.*—It would be tedious to enumerate the variety of flowers that flourish in this district. It may suffice to say, that in addition to those cultivated in the open air in Great Britain, many grow here throughout the year, which there require the protection of a greenhouse.—*Extracts from The Southern Cross, and New Zealand Guardian, Nov.* 25, 1843.

Carnation and Picotee Show.—As the day is fast approaching (the 6th of August) when the Carnation and Picotee Show, open to all England, will take place at the Coppice, near this town, in the grounds of Mr. J. F. Wood, nurseryman and florist, for two silver cups, value five guineas each, presented by him for competition, we are enabled by the kindness of the Secretary to the Committee, Mr. G. J. Robinson, to present to our readers a list of the competitors, amongst whom are some of the best growers in the kingdom:—

Carnation Cup.	*Picotee Cup.*

Observations on the Green Teas of Commerce, by Robert Warington, Esq.—On submitting a sample of Green Tea, supposed to be spurious, and which had been seized by the Excise, to microscopic investigation, the author found that the variation of tints, which had led him to this mode of examination, was dependent on adventitious substances mechanically attached or dusted on the surface of the curled leaves. The principal part of this powder was of a white colour, interspersed with particles of an Orange and of a bright blue. From the abraded dust of this sample, obtained by agitation, some of the latter were separated, and proved on examination to be Prussian-blue; the Orange portion was apparently some vegetable colour; and the white and principal part was found to contain silica, alumina, a little lime and magnesia, and was probably kaolin or powdered agalmatolite, more particularly from the rubbed and prominent parts of the Tea assuming a polished appearance. A great variety of other samples of Teas were submitted to examination, but in all cases they were found to be faced with various substances, to give them the bloom and colour which is so distinct a characteristic of the Green Teas of commerce. The unglazed varieties appear to have had no blueing material applied. Very high qualities of glazed Teas have this facing apparently tinted of an uniform pale blue before application; while others, still of high quality, and embracing the great part of the samples examined, have both the white and blue particles very distinct, the latter varying in its quantity; in the low qualities, as Twankay, being pretty thickly powdered. When this facing was removed, the Tea was found to be of a black colour, but without the corrugated aspect presented by black Teas ordinarily, and which evidently arises from the higher temperature to which they are subjected during the process of curing or drying. The substances separated from these Green Teas were sulphate of lime, a material analogous to kaolin, and Prussian-blue, together with some yellow vegetable colouring body. It is evident that the whole of these Teas come to this country in a dressed or adulterated state, and the onus of this should fall on the right shoulders. The author concluded by quoting various opinions and observations of persons long resident in China, by which his investigations are satisfactorily confirmed.—*Chemical Gazette.*

CALENDAR OF OPERATIONS.

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

About the beginning of August some of the best gardeners treat their established stove plants somewhat like those of the greenhouse for five or six weeks. They either remove the plants to more open houses or throw their stoves open on purpose—removing dwarf, tender, and young, delicate plants into close frames. Whatever conveniences of this nature may be at hand should be made the most of at this time. Nothing can be more injurious to stove plants than keeping them growing late in the season, and thus preventing the ripening of their wood, which renders them more liable to injuries in winter and prevents their flowering freely next season.

Conservatory.—Concerning the varieties of Thunbergia alata, being among the best things for the conservatory at this time, and coming more into fashion every season, I shall again offer suggestions for their management, as some find them difficult to manage. A complete key to the natural or true management of these plants is given in last Number (p. 482), in the notice of Mr. Buckhouse's volume. Mr. B. says they grow in shady places, "much in the manner that Ground Ivy grows in England." From this we may infer that the back borders, or under the large specimens planted out in the conservatory, is the true situation for these plants, where they might scramble among Ferns, roots, or Moss, stones, &c., "after the manner of Ground Ivy." But to improve, or rather to follow out the great improvement which Mr. Fryer has effected, they ought to be planted out in pits early in May, using very rich rough compost, and placing fresh Moss all over the bed; keep the Moss damp and shade the plants in the middle of the day, and allow them run all over the Moss. Beautiful as Mr. Fryer's two new seedlings are, I have no doubt but still greater beauties may easily be obtained from plants thus treated.

Pits and Frames.—The lights should now be drawn off at night, where the plants are of the hardier kinds. Stout cuttings of Plumbago capensis struck now will force next spring for the conservatory, and may afterwards be planted out in beds in the flower-garden, for which they are admirably suited.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department,

We have not had such alternations of wet, cold, and dry seasons for flower-gardening for the last five years, which, if they have taught us nothing else, have convinced me of the impossibility of producing anything like vigorous growth in bedded-out plants by manual labour, let it be ever so well directed. There is certainly a great difference in soils, and plants will grow in one of a free porous nature when they can scarcely exist in one of an opposite mechanical texture; but even under the most favourable circumstances of soil and situation, it is impossible to produce a healthy growth during the prevalence of north or north-east winds, which seem to prevail here during the spring and early summer months, with as much exactness as the trade winds do in more tropical climates. Two of the flower-gardens here were attended during the past dry weather with all the care which the most solicitous could have bestowed upon them. They were regularly watered with warm soft pond water, wetting the soil each time to the depth of at least nine inches; the beds were mulched with short Grass, and the plants shaded in the day time, but with all this they did not grow; under ones became sickly, and those not well established at the time of turning out died, outright. Therefore, What is to be done another season? I direct this question to the flower-gardeners of the United Kingdom, knowing that in the multitude of counsel there is wisdom, and with the hope that many will be induced to communicate their answer to the query. At the same time I should also be glad of a list of such plants as are considered by the growers novelties in the way of bedding-out plants, and more particularly if any are grown which were not mentioned in the Amateur's Garden in the *Chronicle* of last year. I shall next week answer the question, What is to be done? and then proceed weekly with the lists of the best grouping plants.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas and Polyanthuses—Must at this season be kept from excessive rain, and above all things avoid a continuous drip. Nothing ruins an Auricula so soon as wet lodging in the crown or heart. The Aphis must be sedulously attended to and never allowed to get a-head. Tulip-seed continues to ripen: secure the heads as soon as the seed-vessel opens at the top, or the stalk becomes dead; put them in paper bags and hang them up in a dry place. *Carnations.*—The bloom comes on very rapidly, more so than we ever previously recollect. Pollen appears more abundant this year than usual; we have impregnated many blooms this season, always observing to have the bloom operated on, of a good sort and of good colour, and the variety from which the farina is taken as good as we can get it. Continue to layer; a great deal of the success of wintering Carnations well depends on having strong and fairly-rooted layers, that they may be well established in their pots before autumn. Some varieties are blooming better than usual this season. Colcutt's Juba, for instance, a beautiful shaped flower which usually comes short of bizarre, is this season quite up to the mark, whilst the accounts I receive of Colcutt's Brutus confirm me in the opinion I entertained of it some years ago, namely, that it is an extremely course flower as well as uncertain. *Ranunculuses.*—Sad complaints are made from all quarters of the great loss of roots, many collections being nearly destroyed. Seed may now be gathered, as the heads assume a yellow hue.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries—It is a desirable point in the cultivation of the Pine-Apple, that no check should be given to the plants, from the commencement of their growth till the fruit is ripe. Notwithstanding this, there are few gardeners who have not at some period or other been compelled to check some of their plants, by withholding water, to cause them to fruit sooner than they otherwise would do; thus obtaining fruit at the time that it is most required, at a sacrifice of size. This is sometimes the case in large establishments, where a regular supply is wanted all the year round. The leaves should not be allowed to become flaccid, nor the bottom heat to decline. Occasional sprinklings with the syringe should be given, and as soon as you feel certain that the fruit is formed, and beginning to rise from the heart of the plant, give liquid manure in small quantities, and in a clear state, until the plant is quite recovered; when it may be watered and treated in the usual way. Attend to the growth of the suckers, so as to get them well rooted before winter. Shade them in hot sunshine.

Vineries.—Look over the bunches to see if there are any injured or small berries in them, which remove as you go on. The return of dry hot weather is favourable to the increase of red spider; be assiduous in the use of the usual means for checking it. It is easily kept down or eradicated by the syringe where the fruit is all cut. Look to the state of your borders with regard to moisture, where the Vines are swelling their crop. If they are dry, supply plentifully with liquid manure, first loosening the surface with a fork, 1 inch deep, to prevent the water from running off.

Peach houses.—The houses which contain fruit should be kept well ventilated at all times. When the weather is fine, it is not necessary to shut up the houses wholly at night, unless it is wished to hasten the ripening of a crop. Keep all Peach and Nectarine-trees clear of insects, and supply with water regularly as required.

Strawberries.—Continue to lay the runners of the kinds you wish to force in pots, till you have a sufficient quantity done. Let those already laid have plenty of water.

Melons.—(see last week's Calendar.)—*G. F.*

V.—GARDEN, FRUIT, AND KITCHEN-GARDEN.

Apricots.—As soon as the fruit changes colour, keep a sharp look-out for moths and wasps. To keep the first in check, where they are numerous, syringe repeatedly with clear lime-water, wet doing it very late, as otherwise a thin pellicle of chalk would be formed, that would spoil the look of the fruit. Lettuce-leaves, &c., only bruised, rubbed about the wall, after being greased on one side, and smeared every morning. The syringing will also decompose the woodlice, as they do not like wet, and cut-stalks of beans may be inserted in the branches of the trees as traps; but the great remedy is to keep the wall in good order, so as to give them no place for concealment. The following circumstance might furnish a hint:—A month ago they annoyed me by taking undisturbed possession of a Mushroom-bed in a bearing state. I had the covering removed, swept the bed, syringed the walls, killed as many as I could, and run a brush with gas-tar all round the bed. The smell was very offensive for a day or two, but assuredly a woodlouse has been seen since. *Peaches.*—These very hot days are just the delight of the red spider, and whether he establishes his colonies on the underside of the leaves, or on the wall, he will settle secure for a time amid all the battering from your garden-engine. Put plenty of sulphur in the engine, previously made into a paste, so that it mixes equally with the water; or what is better, take Mr. Errington's advice, and daub the open spaces of your wall with it, and then the more intense the heat the stronger the fumes of the sulphur will be. It is as yet the only remedy we possess for expelling or killing the red spider, and I have never known vegetation suffer from its fumes, unless when heated to ignition. *Mushrooms.*—The chief thing to be attended to with beds in a bearing state, is to keep them in a close cool atmosphere, by frequent gentle sprinklings of water on the slight coverings of the beds. Take every opportunity that occurs of collecting and drying horse-droppings, &c., for future beds. *Routine.*—Sow Cabbage for the spring crop, Lettuce and Endive for succession, the last French Beans for the open air, a good breadth of Turnips, Radishes, Onions, &c., for Salads, and Flander's Spinach now, and again in eight days, for early winter use.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Attend to the directions given in recent Calendars. Examine the woods often in order to ascertain what trees may be taken out next season.

Coppice.—As the young shoots from the stools are growing fast, great attention should be paid to thinning and regulating them before high winds, accompanied by heavy rain, occur, which often does much injury to them.

Young Plantations.—Attend to shortening and training the young shoots according to previous directions. By this practice the trees make more progress than those left undone.

Nursery Work.—Attend during the growing season, to thin, shorten, and train the young shoots, if strong handsome plants for speedy removal are wanted.—*W. B.*

VII.—COTTAGERS' GARDENS.

Look over Vines on walls to stop laterals, thin out weak shoots, and keep the rest neatly fastened in. The fruit will now be advancing, and the bunches should be thinned out with a pair of scissors, which is an operation that is very essential to their perfection both in size and flavour. Keep Dahlias tied in; remove weak side-shoots and give them occasionally a watering with manure water; if they are planted in a situation and soil which render mulching necessary, cover the dung over with a thin layer of soil, which will take away its unsightly appearance. Keep Creepers (if any) on the cottage walls neatly trained up, but not so as to give them too stiff or formal an appearance; free them from all dead leaves. It is of great advantage to Cucumbers that are planted in the open air, to cover the ridges with clean Straw or Pea-haulm, before the plants are too far advanced. This keeps the sun from parching the ground in hot dry weather, and prevents the blossoms and young fruit from being covered with soil during heavy rains; it also, in a great measure, preserves the fruit from becoming spotted, when the autumn is wet and cold. Towards the end of the week, prepare a small bed and make a sowing of Early York and Vanack Cabbages, to come into use in spring. Thin out young Turnips as they advance; hoe between the rows of growing crops, and keep down weeds.—*J. M'H.*

State of the Weather near London for the week ending July 25, 1844, as observed at the Horticultural Garden, Chiswick.

July	Moon's Age.	Barometer. Max.	Min.	Thermometer. Max.	Min.	Mean.	Wind.	Rain

Notices to Correspondents.

Soehaba Clover.—*A Constant Reader.*—This is a coarse annual stemmed plant, growing 7 or 8 feet high. Alcohol, when decomposed, may be useful to plants; undecomposed, it must be injurious.

Country Shows.—*John Sillobs*, or *Snobs*, or *S. Shobs*, or *Schobs*, (for we cannot read your signature,) you do not say *what* Show your report belongs to. What Society is "this Society?"

Currants.—*F. X. O.*—The origin of the Black Naples Currant is unknown to us. It has existed in the Garden of the Horticultural Society since 1824, when it was obtained from the Nursery of Messrs. Dickson, of Edinburgh.‡

Diseases.—*J. B.*—Certainly, where the flower-buds of shrubs produce nothing but leaves it is a disease, caused by an excessive supply of food. We should like to know how the ingenious gentlemen who set up against Morphology can explain such things without reference to its principles.

Missing Sorts.—*An old Subscriber.*—Common sense says that the words "That no flower, &c., being burst, artificially supported, or otherwise imperfect, be entitled to take a prize," applies to Carnations, and plants of that sort. If it is maintained that it applies to Moss used in forming a ground for Roses, the decision must be arrived at by some other sense than common sense.

Heating.—*A Subscriber.*—We do not sell heating apparatus. Consult the advertisers. Yours is a very little affair, and hardly fit for an apparatus. Consult the paper by "Dion," at p. 326, vol. 1844, and try to make an apparatus for yourself; if you are a clever man you can easily do it.

Grapes.—*A Reader.*—The following are good kinds, which bloom throughout the summer:—Veronese, Bubilora, vestita coccinea, v rosea, sulphurea, Hartwelli, tricolor, ampullacea eximia, vahliana, Bowkeri, amabilis, viridiflora, irisyana, rotulgens, retorta, purpurea, Mawonii, grandiflora, Altoniana, depressa, Cavendishii, and the several varieties of Ventricosa.—For Camellias, see p. 430 of this year.‡

Humphreys's Botanic Compound.—We have received from Mr. Humphreys another letter, which commences in the following words:—"As it is now obvious that the object of the late attacks on this subject has been to injure the sale, *by the fabrication of fictitious chemical details* as to its nature," &c. This language, which is as false as it is offensive, at once excludes the writer from a future place in this Journal, except in the advertising columns. Our object has been truth, and that we have gained. Our business is to enlighten the public, and that we have done. We have shown that the so-called Compound is nitrate of ammonia, with some trifling impurities, and a mere trace of phosphoric acid; and we have thus enabled gardeners to judge of its real value. Mr. H. was greatly mistaken if he thought that we were to be driven from such a course by either fear or favour.

Hybrids.—*Clericus.*—The greater part of the Fuchsias in cultivation are mules, and barren. If you want pollen you must go to the original species, or you must examine your mules till you find good pollen. The pure parents are the best to use, at least on one side or the other. Without pollen you cannot cross. Let your Dahlias alone; the side-shoots will grow in heat, but will do no good now.

Insects.—*F. H. S.*—Your Caterpillars will change to the Vapourer Moth, Orgyia antiqua, described and figured in the *Gard. Chron* vol. ii. p. 540; they feed on a variety of plants, and occasionally do great mischief in the squares of London. Nothing but hand-picking and destroying the apterous females and the clusters of eggs can afford you any relief. *It.*——*A Subscriber.*—If your query was not answered your letter never came to hand. The maggots infesting your Cauliflowers, &c. will produce a Fly, probably the Anthomyia ceparum, whose history was given in vol. i. p. 395 of this Journal, and you must consult the "Royal Agricultural Journal," vol. iv. p. 128, where the best mode of extirpation is recorded. *R.*——*J. Butterfield.*—Your luminous animals are female Glow-worms. *It.*——*J. M.*—The Slug-worms infesting your Pear-leaves are the larva of a Saw-fly, named by Linnæus Ten hredo cerasi, whose history you will find in the 2nd vol. of the *Gard. Chron.*, p. 692. *It.*——*A. B.* Thanks for your notes and supply of infested Barley. *R.*——*A Constant Reader.*—Your Pear-tree leaves have been eaten by the larvæ of a Moth called Argyromiges Clerckella, which is figured in the 1st vol: of the *Gard. Chron.*, p. 261, where its history is given, and the best means of getting rid of the disease. Whether your Ribstone Pippin be affected by the same Caterpillar we cannot determine without seeing the leaves; the Pelargonium spots arise from a very different cause. *R.*——*A Subscriber, Waterford.*—It is impossible to advise you in the absence of specimens of the insects, and a portion at least of an infested leaf. *R.*——*Aliquis.*—We believe your Shells are the Helix memoralis, but they are so mutilated that it is difficult to determine the species. *R.*——*R. W.*—Your Oak gall will produce the Cynips gemmæ. *R.*——*A Constant Reader in the North.*—Please to send us some of the black scales affecting your Vines, and we will tell you what is best to be done, for as the females are stationary, and the young ones scarcely visible, we think you must be mistaken in supposing they come out of the earth. *R.*——*N. O. P.*—We should be happy to comply with your request, but the Caterpillar was crushed perfectly flat. Lucifer boxes are no protection by post, but if you will send us a Caterpillar or two in a shallow pill-box with a piece of cork stuck in the centre, we shall feel obliged, as this enemy to the Carnations is an interesting and novel fact which we are desirous of investigating. *It.*

Morphology.—*J. S.*—We would strongly advise you to turn your attention to things you understand. We really cannot inflict your ignorance upon our readers.

Manures.—*C. J. P.*—We have had no experience with horn-dust, and therefore cannot give an opinion respecting it.‡

Names of Fruit.—*A Constant Reader.*—Your Pear is the Citron des Carmes.‖

Names of Plants.—*L.*—Tropæolum pentaphyllum.——*A. B. C.*—Certainly not Clerodendron splendens, nor at all like it.

Oaks.—*A North Briton.*—The cause of the disease of your Oaks could only be determined by personal inspection. It is impracticable to say what is the matter without that.

Pelargoniums.—*A.*—Turn them out of doors for a fortnight to ripen the wood, then cut them back, both top and bottom, shake them out of their pots, and repot in fresh soil.

Pot Pourri.—*J. B.*—The following receipt is excellent:—Put into a large China jar the following ingredients, in layers, with salt strewed between the layers: two pecks of Roses, part in buds and part blown, Violets, Orange-flowers, Jasmine, and anything sweet—a handful each; Orris root, sliced, Benjamin, and Storax, 2 oz. of each; ½ oz. of Musk, ½ lb. of Angelica-root, sliced, a quart of the red parts of Clove-Gillyflowers, two handfuls of Lavender-flowers, half a handful of Rosemary-flowers, Bay and Laurel leaves, half a handful each; also of Knotted Marjoram, and Balm of Gilead. Cover them quite close; when the lid is removed the perfume is very fine. When the above has been in the jar some weeks it is advisable to empty it entirely, stir it well with the hand, and return it into the jar again.

Preserving Skins.—*J. M. C.*—You must consult a work on Taxidermy; we cannot give up space to such a subject as bird-stuffing. The booksellers will readily set you up.

Raspberries.—*Messrs. Youell and Co.*—The samples of Fastoliff Raspberries which you have sent are fine, large, good-looking fruit.‡

Royal Botanic Garden, Regent's Park.—*Scrutator.*—This time you are probably right. It may be true that one of the Judges of Roses at the last meeting was also an exhibitor, and assisted in giving the first prize to himself; and if true it did his good taste no great credit, and it was decidedly wrong on the part of the Regent's Park Society to have made him a Judge. But, supposing this to have happened, there can be no doubt that the Managers of the Regent's Park Garden will take care to avoid in future such an oversight as making a Rose Exhibitor a Rose Judge. If it should again happen, it will then be time to attack the Society on the subject; but not till then.

Soils.—*U. J.*—By all means mix Guano with farmyard dung, but mind that it is not allowed to become wet and then drain away. It may become wet, if you like, but the drainage must be all thrown back again. We should dig it in early next spring. We never before heard of a "lug" of ground. How much is that? Move your Apple trees on the 1st of November, or as near that day as you can.

Strawberries.—*S. B. P.*—To Keen's Seedling you may add Myatt's British Queen, Elton, Grove-End Scarlet, and Downton. We would prefer planting in rows, with three plants in each patch.‡

Miscellaneous.—*Enquirer.*—We really do not know what we can add to our own opinions upon planting and pruning, beyond what has been already stated in our columns for the last three years. It is an entangled subject, and you had better consult our previous volumes. If your plants are bushy-headed cut them down, except Beech, and watch with care the new shoots that will be thrown up. Thinning is the great thing; pruning we esteem but lightly, except in particular cases. Prune Laurels in April. Knight's Dwarf Mignonette is the best late Pea. Employ Potter's guano, or superphosphate of lime, the last best. Why not let your Vines lone? There is no earthly reason against it, only sifting with water, and when in full fermentation, and not of vitriol carefully fill afterwards cracks, or move a plaster among it, or if you are practical leave it till it loses its causticity. It is the most valuable of all manures. Steep guano in it, and try it on Camellias.——*A Subscriber.*—After your Calceolarias have done flowering they may be placed out of doors in a shady situation, until the young wood becomes sufficiently ripened for putting in cuttings of them. Allow your Achimenes to dry off, withholding water gradually until the stems become withered, when it may be stopped altogether. From your Pelargonium seed that has not been fertilised with other kinds, you have a chance of raising something different from the parent plant, as Pelargoniums are varieties, but seeds of your Fuchsias, if they are species, are likely to reproduce the same thing. We cannot tell where Meyer's rat poison can be had.‡——*S. E.*—We are not aware that there is any preparation that put on zinc labels to fit them for retaining the ink.——*A Reader.*—For information regarding gold fish, we would refer you to p. 213 of the present year.‡——*A Lady Gardener.*—We cannot recommend Nurserymen.‡——*A. J. B.*—You can have 27 of the Numbers you write for; the others are out of print.——*Rusticus.*—Skeletons of leaves are made by maceration in plain water till all the parts are soft, then washing and picking out the soft parts with needles, and then steeping for a little while in very weak muriatic acid. It is a difficult and tedious process. Gather the leaves when full grown.——*W. C.*—May add to his Conservatory climbers Hardenbergia macrophylla and Mandevilla suaveolens.‡——*Somerset.*—You had better allow your Raspberries to stand, and have patience until another year, when probably you will have suckers. We presume your Salvia is S. mexicana. To flower it, it should be grown in a pot, and should not have too much pot room, as it is apt to get over-luxuriant. It also requires to be freely exposed to bright light during the summer months.‡——*E. E.*—Two good Cabbages to be sown about this time for spring use are the Early York and Vanack. There is no evidence to show that the moon has the effect of causing or preventing them from running to seed. Ground for Onions should be bastard-trenched and ridged late in autumn, and manured at the same time. Nothing, therefore, is required when the seed is sown in spring but levelling down the ridges.‡——*J. A. A.*—The glow-worm is not destructive in flower-gardens. For its history, see page 443 of the present year.‡——*A Reader.*—Will find excellent directions respecting the management of Cape bulbs, given at p. 774, 1843.‡——*Hibernicus.*—For a method of trapping Wasps see p. 260 of this year. Let the weak side-shoots of your Dahlias be thinned out; they are not worth the trouble of putting in for cuttings, as Dahlias are so easily increased in Spring.‡——*Chemical Jack.*—We are sorry, but cannot remedy the evil of which you complain. Speak to the agent who supplies you.——*J. H. H.*—Depend upon it the Vine you speak of was not a Vitis, nor its fruit Grapes of any kind. There is no such thing, as far as we know, as a herbaceous Vitis. There are plenty of Vine-like plants, herbaceous, and bearing berries; but what you may have seen we cannot tell; perhaps some Bryonia.——*Medo.*—We are unable to explain the first cause. There is no doubt that the curling in your pods of stock arises from one side being injured and made incapable of growing as fast as the other. But what may have injured it and made it so we see no means of explaining.——*N. O. P.'s* question is not forgotten.——*Ainus.*—You will find all about Anastatica at p. 363, of 1842. The reference is omitted by some negligence of the person employed to make the Index. The seeds cannot be bought in this country. It has possibly been cultivated, but we never saw it.

SEEDLING FLOWERS.

Antirrhinum.—*Z. Z.*—If 29 is a seedling it must be a repetition of caryophyllideles. 30 is handsome and well formed. 33 is pretty, but not new, and the lower lip does not spread, as it does in 30, which is a very perfectly-formed flower.*

Fuchsias.—*W. J. E.*—We are obliged by the sight of your flowers; they are very good as a collection. 3, 9, and 10 are very fine.*——*E. T. S.*—The sepals of your seedling are too long; and there is nothing new in the colour to recommend it for general cultivation.*——*W. R. and S.*—Your seedlings are large, stout, and showy flowers, but in colour they are similar to the varieties in cultivation; 3.44 is the best.*——*Z. Z.*—A large, stout, and rather coarse flower, not differing in colour from a great many already out.*——*W. S.*—As a variety for bedding out, or planting in the border, your seedling No. 10 is an excellent variety; it appears to be a robust grower, and is the most prolific bloomer we have seen, bearing several flowers at every joint; the flowers are large, rich in colour, and measure, from the base of the footstalk to the end of the pistil, nearly six inches.*——*C. D. M.*—*No.* 1. The sepals to this variety are long and coarse, and there is scarcely any distinction in colour between the corolla and the rest of the flower. 2 is a better flower, elegant in form, but wanting the purple in the corolla: this is the best seedling. No. 3 is small, and though bright and pretty in colour, the proportions of the flower are not good.*——*Y. C.*—Your seedling is a showy variety; rosy carmine tube, with sepals tipped with green; the corolla purple crimson, and very large for the size of the flower.*

Petunias.—*D. J.*—Your seedling is a delicate and pretty variety, and the changes it undergoes after the flower opens, of a purple-crimson to various tints of blue, increases its value.*——*Z. Z.*—Your dark-veined Petunia is a pretty variety, but not very new or striking.*——*W. G.*—It is impossible to form an opinion of your seedling, from the flowers being pressed flat between paper; they were so bruised that the colour was entirely gone; they travel best in damp moss.*——*J. S. S.*—Seedling Petunia, rich purple crimson, spotted, and occasionally striped with white; the spots are distinct, but the flowers are rather small. We should like to see it again, in about a fortnight. It will make a good border variety.*

Pansies.—*W. J—n.*—Your Pansy is of no value, the flower not having a clear ground colour; this part of the flower is blurred and imperfect.*

Pelargoniums.—*R. W. and Co.*—*Formosissima* is your best seedling. The flower is well formed, but the top petals want smoothness; and though common in colour, it is delicate and pretty. *Teniers* was too far gone to form an opinion of; and *Rubens* and *Maid of the Valley* are ill-formed and destitute of novelty.*——*F. C. B.*—Your seedling scarlet is of a very rich and intense colour, and resembles in intensity a variety known as the Brighton Hero. The trusses are very large and compact; the one sent contains between 70 and 80 buds and flowers.*——*J. Y.*—The petals of your flower had fallen; they appear thin and deficient in substance, and the form of the flower we should judge to be too long; the top petals are rich in colour.*——*Eleanor.*—Your white seedling, No. 18, is a good flower, well formed; the spot decided and the white pure: it would have been more welcome with the spot and other colour. The top petals to 19 are too pointed, and the colour and surface too uneven; the lower petals are broad and clean, and the flower is good in substance.*——*W. E. G.*—Your flower is good in colour, but deficient both in substance and form as a show variety.*——*J. M.*—Your seedling is a flower of good form and substance, but it is unfortunately of that lilac colour which is now discarded from every good collection.*

Verbenas.—*Z. Z.*—There is nothing new or particularly attractive in either of your seedlings; they are similar in colour to varieties in cultivation.*

*** As usual, many communications have been received too late.

SEED WHEAT.—Any one desirous of ascertaining the kind best suited for next year is invited to inspect the varieties of Wheat, BRIDGEWATER HOPETOUN and MORTON'S RED-STRAW WHITE, 120 acres of which are now growing on WHITFIELD FARM, THORNBURY, GLOUCESTERSHIRE.

The present is the only season of the year when the value of any variety of Wheat as Seed can be ascertained, by inspection; for, if the examination of a mere sample of the grain, which can be seen at any time, be nearly uninstructive as to its quality in the eye of the baker (see *Ag. Gazette*, No. 5), it is entirely so as to the productiveness or habit of growth of the variety to which it belongs. These points, which are of the highest importance in the eye of the Farmer, can be ascertained only by an examination of the growing plant when in full ear.

JOHN MORTON, Whitfield, Thornbury.

The Agricultural Gazette.

SATURDAY, JULY 27, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, July 31 — Agricultural Society of England.
Thursday, Aug. 1 — Agricultural Imp. Soc. of Ireland.
Wednesday, Aug. 7 — Agricultural Society of England.
Thursday, Aug. 8 — Agricultural Imp. Soc. of Ireland.

FARMERS' CLUBS.

July 30 { Framlingham. Isle of Thanet. Rayleigh. | Aug. 2 Collumpton.

We have to direct the attention of our readers to the Report, in other columns, of the MEETING OF THE AGRICULTURAL SOCIETY OF ENGLAND AT SOUTHAMPTON during the past week.

The exhibition of implements, to which, in keeping with our leading principles (see No. 1), we have devoted the greater part of our attention, has greatly surpassed its predecessors, not only in the money, but in the agricultural value of the machines shown. This Exhibition possesses not only a positive interest, depending on the usefulness of competition amongst machine-makers, but it possesses also a relative interest, to be ascertained by a comparison of it with those of previous years, inasmuch as it exhibits the progress of improvement in that important subject—agricultural mechanics. We have endeavoured to exhibit, by a comparative statement, the relation in which the show of implements at Southampton stands to that of the previous year at Derby. This will be seen, along with other remarks on the subject, in another place.

Though the subject of Machines of Carriage will come to be considered more in detail in the course of a series of articles on Agricultural Mechanics, which we hope soon to lay before our readers, yet the present being a seasonable time for a discussion of THE MERITS OF THE CART OR WAGGON FOR HARVEST PURPOSES, we shall just state the points on which such a discussion must turn. Our own opinion is, that for these, as for most if not all farm purposes, the one-horse cart is the most economical machine in use; but the result of a well-conducted comparative trial might prove unfavourable to this view, and yet arable farmers who hold it might still be perfectly justified in refusing to use waggons instead of carts—and this, on the only ground which can commend itself to the practical man—on the ground of true economy. For, to take a case, we happen to know a farm on which, in winter and spring, 2400 cubic yards of manure were last year carted from the steading to the fields; on which, in autumn and winter, about 1400 tons of Swedes, Mangold Wurzel, Carrots, Potatoes, and Turnips, were carted from the fields to the steading; on which, in summer and autumn, about 700 cart-loads of Corn, Hay, and Stubble were carted home. Now, was it the interest of the farmer in this case to change his carts for waggons, though it might be proved that he would have saved by it in harvesting his 700 loads of Corn, when he would so manifestly have suffered by the change, with reference to five times as many loads of the less bulky material—manure and green crops? We do not suppose the experience of every or of many arable farmers is similar to that of the one we allude to, but we just mention the case, to convince those who hold the superiority of the waggon over the cart in harvest-time to be self-evident, that others may agree with them in opinion on this point, and yet reasonably differ from them in practice.

This farmer needs *all* his present number of carts when hauling manure in winter and spring. Is it his interest to purchase, in addition to them, as many waggons as he will require during Corn-harvest, merely to obtain the small differential advantage which we will suppose him to receive from them at that season? This advantage would need to be a great one to justify an affirmative answer. But we believe, where well-constructed carts are in use, the employment of waggons at harvest-time in their stead, in place of being advantageous, would entail a loss upon the farmer.

The implements and furniture of a farm form a large item in the account of capital invested in it, and the purchase of a greater variety than is necessary is obviously most unwise: the aim should be, not to have a machine for every separate purpose, but to get a machine to perform as many purposes as possible.

To no class of implements do remarks on variety being inconsistent with economy apply more than they do to machines of carriage. There are waggons for the carriage of heavy goods, and waggons for the harvesting of Corn or Hay; and there are three-horse, two-horse, and one-horse carts; while the purposes for which all these are used may be effected, we believe, as well by the use of one of them. It is needless to describe all the various little differences in the construction of these machines. They vary in dimension; some have attachments in front and behind, by which the length, and on either side by which the width, of the load may be increased. Some have broad wheels, which are necessary in harvesting Hay or Corn off the wet undrained districts in which they are used; others have narrow wheels, more fitted for the carriage of light loads on good roads.

In the practice of many well-farmed districts, it is shown that one form will answer certainly all the farm purposes, and perhaps almost all other purposes for which this variety is used. Economy requires a form of carriage which, while it will just hold a heaped load of dung, or a flat load of earth, or stones sufficient for the draught of one horse, may, by a simple means of increasing its size, be enabled to hold an equal weight of Straw or Hay.

On this subject we shall hereafter enter more into detail; at present it is sufficient to say, that if, as we know to be the case, a framework supported by only two wheels may be made to carry a full load for one horse—say 24 cwt.—of Corn in sheaf, the only result which could follow a union (in point of size) of two such frameworks supported by four wheels would be that injurious one of increased awkwardness and unmanageableness.

But let us for a short time consider the general question of cart *versus* waggon. There are many advantages possessed by one horse carts over carriages requiring two or three horses to draw them. The second and the third horses, in the latter case, cannot exert themselves to such advantage when in trace harness as if each were between shafts. The strength of the foremost of a long row of horses, and of each of the others, in proportion to their distance from the weight, is expended on the useless labour of keeping those behind him in a straight line. This is particularly observable on going up a hill, when a horse naturally pulls to a side to try to lessen the draught. Unless they are under a skilful driver, some of the horses will be seen pulling one way, and some in another. On going down hill, again, the faults of this plan are equally evident, for the whole weight of the machine comes on the shaft-horse; while, were it divided amongst three or four in separate carts, each would have his share.

In an interesting Paper on this subject in the second volume of the Agricultural Society's Journal, the author states that he has, *after trial*, abandoned the heavy waggons of the district, and substituted in their place, for all farm purposes, the light one-horse cart; he states that the only objection to the one-horse cart system is, that the weight on the back of the animal distresses it. Now, here we think he is wrong; this weight, to which he objects, we believe to be both directly and indirectly advantageous. Directly—for if there be a portion of the load on the back of the horse, there will, of course, be less on the cart for him to draw. When an excavator loads his barrow with earth or stones, he loads it near the handles, that by having more to carry he may have less to wheel. And it is, we believe, *indirectly* beneficial; for when there is a portion of the load on the horse's back, he is better able to draw that which rests on the cart; his feet are firmer on the ground, of which he has thus a better hold, and along which he is of course better able to pull a heavy load; this may easily be seen when he is pulling up hill: the carter then always loads his cart forwards. If a pressure on the back of the horse enables him to draw a heavy load up hill, it will, to a certain extent, also enable him to support a heavy load without slipping on going down hill. There is no doubt, however, but that from a badly arranged load the animal will suffer going down hill, as the pressure is of course increased the more that the centre of gravity of the load is thrown forwards. To remedy this, the author of the paper alluded to recommends three ways. Two of these certainly tend to diminish this weight, though not to take it away. In one of them it is proposed to lower the box of the cart and pass the axle *through* it, so as to have some of the load below as well as above it. In the other, the author simply proposes to lengthen the cart and diminish the height of the load; and he gives a drawing of a very neat Corn-cart on this principle, of his invention. The third method which he suggests is, however, evidently founded on a mistaken idea, (see page 79, vol ii. Society's Journal). He proposes to load the cart at either end "so as to leave the middle space empty, so that, at the greatest descent it has to meet with, no portion of the bulk shall pass the plumb line" from the axle. "consequently no overbalance can take place, no weight can be thrown forwards." But the author forgets that it does not matter whether each of the two loads is on its own side of the plumb line; we must not only look at the fact, that the two equal weights are on either side of the axle or fulcrum, but we must look also to their distances from that fulcrum, and we shall find that if the cart be inclined, as when going down hill, both the front and hind portions of the load will be thrown forwards, the one portion from, and the other nearer to the plumb line from the axle, and thus the weight on the horse's back will be increased as before. If this weight be inconveniently great, the proper and simple remedy is to raise the shafts by taking up the back band of the shaft horse, and loosening the belly-band; or the load may be raised in front, and so thrown backwards, if it be a *till* cart, by means of the rail in front, which most carts of this kind have for that purpose.

We have digressed somewhat from the question which first engaged us, viz. the merits of carts or waggons for *harvest purposes*, and in returning to it we would just say how only this point can be properly determined. If ten or twelve practical men, farming similar extents of similar land, and following the same method of harvesting their grain, excepting that so many used waggons and so many carts, were to keep a journal of their harvest operations, specifying the number of men, women, children, and horses, respectively employed strictly in harvest work, so many *hours* in *each* field—if they were to keep the Corn of each field separate and measure the *bulk* of it a month after harvest when it might be supposed fairly to have settled—and if they were to measure the distance of each field from the stack in which the crop off it was built, a comparison of those journals by any one acquainted with the general character of the crops on each farm, and with the strength and activity of the men and horses at work on it, would determine the question of the relative merits for harvest-work of the carts and waggons employed. The question is a very interesting one, and we should be glad to join with any, in an attempt of this kind, to answer it.

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

It is necessary to state at the outset, that in drawing up the following remarks, the various subsoils or geological strata occurring in our district are described in the reverse order of their deposition, commencing with the uppermost, i. e., the kerse or alluvial land along the sides of the Severn.

Alluvium.—Along the eastern side of the Severn there is an extensive tract of alluvial deposit. Its eastern boundary, which is everywhere its junction with the marl of the new red sand-stone, lies, from Shirehampton on the Avon along the edge of the hills by Over and Almondsbury to Olveston, where it turns north-west, by Ingst and Aust. This constitutes the chief portion of the alluvial district. Another division of it, connected with this by a narrow band of land between Aust and Ingst, on the alluvial level, runs in a narrow tract along the shore to Oldbury, being bounded thus far by the rising ground between Littleton and that village; from Oldbury, the boundary of this tract runs south-east towards Thornbury, up to Rockhampton, Hill, and Berkeley, where it is terminated abruptly by the Little-Avon, up the banks of which a narrow band on the alluvial level runs as far up as Stone. The shore of the Severn from this to Oldmoor Cliff, north of Purton Passage, is abrupt. Near this, another tract of small extent commences, the principal portion of which gets the name of the New Grounds, having been taken from the Severn by embankment many years ago. This alluvial deposit is generally of a light blackish-brown colour, but towards Berkeley the colour is ruddier than anywhere else. It is a calcareous clay, produced by the degradation of the clays and limestones of the blue lias, and of the marls of the new red sand-stone, through which the river runs. Under the head *Alluvium*, also, must be placed those fertile districts down the sides of the many streams which everywhere intersect the county. The nature of the soil on these, of course, varies with that of the district through which the streams flow; thus, the soil on the banks of the streams down the valleys in the oolitic district is a rich calcareous loam, while that similarly situated in the coal district is either a stiff clay or a keen sand. The land on the alluvium is almost wholly pasture. Perhaps, out of a farm of 200 acres, a field of 6 or 7 acres may be arable. The fields are not small, and they are seldom crowded with trees. The Elm is the hedge-row tree. Orchards flourish on this soil. The small extent of arable land is generally cultivated wholly for the farmer's own consumption, for which, indeed, on many farms, it does not suffice. Wheat and Potatoes are the chief crops. Beans are also occasionally grown. The average of the Wheat-crop is from 28 to 30 bushels per acre—higher than anywhere else in the district; the Potato-crop is also generally good. These crops are, however, as in all cases on clayey soil, much dependent on the weather: a wet autumn and mild winter, or a dry season in spring and summer, are equally injurious: and

in this, in great measure, consists the difference in value existing amongst clayey and deep or shallow sandy soils: in the first case, the soil is easily injured by extremes of either kind of weather, and land of this kind is here frequently termed "casualty" on this account. In the case of a shallow soil, one resting on rock, injury is received only in very dry weather—the wetter the season is, the better for it; and in the case of deep sandy soils, although the crops are dependent in some measure on the weather, yet the injury received from extremes of either wet or dry is comparatively small. It is the great advantage of drainage, when accompanied by subsoil ploughing, that it removes superabundant water during a wet season, and affords a source of moisture in a dry one, thus tending to render all soils independent of the weather. The alluvial district, being perfectly flat, and also of considerable extent, a very slight fall can be obtained for water, and the drainage of the land, when attempted, is most imperfect. Almost universally, however, no drainage has been attempted—the occasional clearing out of the ditches being the only attempt to dry the land. The scourings of the ditches, mixed with the dung taken off the pasture-land, is all that the land to be mown receives; and this cannot be given to it each year. An average crop of 25 cwts. of Hay per acre is cut each year; and the value of the early spring and autumn feed is greatly beyond that of any other district of pasture-land in the county. Out of 30 square miles, which is the extent of the alluvial district, at least two thirds are mown each year.

Gravel.—Beds of gravel occur covering the clay of the lias near Slimbridge and Frampton, and also at Eastington and Stroud. They are generally of no great thickness; in the centre of that, however, at Frampton, the wells dug for water do not reach the clay. These diluvial deposits consist of fragments of calcareous rock, generally of a rounded flat lozenge form, varying from one or two inches in length to a mere sand. They must be due to the degradation of rocks of the oolitic series, as they are formed generally at the mouths of the large valleys which here intersect those strata; and the gravelly form is more perfect, the fragments are more perfectly rounded, the farther they occur from the oolitic district. Besides these extensive deposits of gravel there are numerous cases in which mere traces of a deposit exist; and these, though existing in so small a quantity, exert a great influence in improving the character of the soil overlying them.

Agricultural Character of the Gravel.—The surface of the district covered by the gravel is level, and, as has been already said, is comparatively bare. Fewer trees exist in the hedge-rows, when we compare it with the densely-wooded country surrounding it, and the fields are larger. The land is chiefly arable. Most of that at Frampton, for instance, is arable; perhaps, however, the half of that occurring at Eastington is pasture. The soil is a calcareous loam, not generally partaking much of the gravelly character of the subsoil. It varies in depth from upwards of a foot to less than three or four inches, constituting in the one case some of the best land in the county, but being in the other easily scorched by a drought of any continuance. It is a light soil, but when wet is apt to clog, and roll up before the plough; the plough in general use is of an old-fashioned form, having a large flat wooden mould-board, inclining backwards at an angle of 30° to the line of draught. This, one would think, would form a most imperfect implement, tending rather merely to push the furrow slice aside, than to turn it over; but when the land is wet, the farmers prefer it to the more elegant iron implements used in some parts of the county. It is generally drawn by three horses in a row. The subsoil is of a more retentive character than, from its gravelly nature, might be supposed. The water stands in the ditches in the fields near Frampton, during wet weather of any continuance. The greatest improvement might be effected here by the use of the subsoil-plough. The porousness which would thus be given to the subsoil, would render drains effective, though placed at very considerable intervals. The greatest difference is observable in the management of land on the gravel. Two farms over which I went, presented a great contrast. On one the four-field system was adopted, for which the soil is remarkably suited. On the other no system at all was followed. Sometimes Wheat was followed by Beans, which were succeeded by Wheat; after which the land was fallowed, and then Wheat again taken; or Wheat was taken during two successive years; or it was followed by Barley, and then after one year Clover. Wheat was again taken; or sometimes, Wheat being twice taken in a four years' course; the intervening crops were Potatoes or Swedes, and Vetches or fallow. The consequence was, that in the one case the land was clean, and the crops good, while in the other the land was foul and the crops inferior. These instances, though occurring at a considerable distance from one another, were on precisely the same kind of soil, and they show how much the value of land depends on the cultivation it receives. The four-field course is adopted near Frampton, Wheat, Turnips or Swedes, Barley, and seeds occurring in succession. The average crop of Wheat is above three quarters to the acre: the Red Straw Lammas is the kind generally sown. Indeed, this variety is held in general estimation all over the county. White Wheats are seldom sown. The Wheat is always sown in autumn, generally towards the end of September; when, however, forced by weather to postpone the sowing till spring, Spring Wheats are seldom used—the seed is not changed. The crop following Wheat is generally Turnips or Swedes. This is sown broadcast; the plants are singled out in the usual way, when the rough leaf appears, and a second hand-hoeing is till the cultivation they receive. Large crops are therefore seldom raised, and when they do occur, are due to a fortunate meeting of circumstances, more than to any excellence in the mode of their cultivation. I should think eight or ten tons per acre was above the average of this crop on this soil. The Turnip-crop is eaten on the land by sheep, or taken to the yard, according to the necessity and will of the farmer. If he be well provided with Hay, it is given partly to fattening oxen in his yard, or feeding stalls, and partly to sheep on the land; if otherwise, however, he is forced to use it for his dairy stock. The Turnip-crop is succeeded by Barley. Being a Barley soil, good crops are raised on it; four to five quarters per acre are perhaps above the average. Clover seeds, and the common Rye-Grass are sown with the Barley, and, after remaining one year down, are broken up for Wheat. The old pastures on the gravel are close and sweet, but very short. The crop of Hay is entirely dependent on the weather; it is very easily scorched by dry weather. An examination of the waste land on the gravel, shows that the unassisted fertility of this soil is very great. Frampton Common is the finest in South Gloucestershire, and perhaps one of the finest in the kingdom. The Grass is naturally good; no weeds of any kind are to be seen. The Common is surrounded by houses and trees, for which it forms a most beautiful natural lawn. The following facts relative to the value of the soil on this deposit, show how great an improvement may be permanently effected in soil, by the admixture of earth of a kind different to that chiefly occurring in it. The land on the gravel near Frampton is valued at 25*s.* an acre. The land on the clay, on which the gravel lies, is of a most perfectly opposite character, and is valued at 20*s.* per acre. There is, between the two, a band of soil where the gravel thins out over the clay, which is valued at 35*s.* an acre. This band is about 70 or 80 yards wide. These valuations were made by a committee of farmers, appointed by the parish for the purpose of apportioning a new rate. This great difference in the value of the land around the edge of the gravel, is also observable, though not in so marked a manner, at Eastington. It was explained by one of the farmers who observed it, by supposing that while the soil on the gravel is easily burnt, and the soil on the clay easily injured by wet, that lying between the two will not be liable to injury in either way: it will possess the lightness of the gravel, and the roots of the plants cultivated on it will at the same time reach down to the clay. The soil in this narrow band is evidently due to a mixture of the clay and the gravel.

WINTER FOOD FOR DAIRY COWS.

In several Numbers of the *Gazette* opinions have been given about food suitable for dairy cows in the winter season; having experimented a little on this subject myself, I may perhaps be able to add somewhat to the stock of information already given to the public. I will first set out with the articles my experience has proved to be deleterious, as far as the flavour of butter and cream are concerned. About 15 years ago, Mangold Wurzell was puffed off by certain parties as leaving nothing to be wished for, as winter green food for dairy cows. The increase of milk from its use was said to be extraordinary, and the butter was rich in colour and highly flavoured; as one of the many dupes to this figment, I allowed about a bushel *per diem* to be given to each cow, with as much hay as she would eat; a fortnight's trial was quite sufficient to put an end to the experiment; both the butter and cream were declared to be disagreeable, and unfit, from their acrid taste, for all table, and many culinary purposes. Common Turnips and Swedes need no comment; every one that has tasted the milk or butter of cows fed with them is satisfied of their unsuitableness for the dairy, and the same may be said of Cabbages, Rape, &c. Brewers' grains, if given in any quantity, give their own peculiar flavour to the butter. The last article that I shall notice as one to be avoided, is old after-pasture, when the Grass is withered, in the last two months and in the first three months of the year; this Grass, in wet weather, imparts a disagreeable rankness to butter, that not unfrequently attaches the blame to the dairy-maid; because the cows having had nothing but Grass, the cause is unaccountable. Among the articles that give increase of milk and well-flavoured butter, good oil-cake holds a prominent place—one in the morning and one in the evening will have an astonishing effect; to this may be added bran or pollard, where it can be had reasonably; two or three gallons twice a day will greatly increase the milk; and with the bran, if the cows have a taste for it, may be mixed a gallon or two, or more, of malt-dust; all these give a rich flavour to butter, and increase the quantity of milk. Of roots, I have found three to be great and agreeable assistants to dairy produce: of Potatoes, every table-variety—Carrots, red and white, and Parsnips. The first named I use sparingly—about two gallons a day, sliced raw, and about three gallons of each of the other roots sliced also, and *mix them* all together when I have the opportunity; as long as the Potatoes are fit for table-use, so long they may be given to the cows, but as soon as they become spotted and of an earthy taste, they are no longer fit for dairy cows; the other roots may be given as long as they continue sound; nothing decayed or mouldy must be given; one ill-flavoured root will spoil a whole churning. The butter, from this plan of feeding, is delicious—superior to other winter butter I have hitherto tasted.—*J. Hinde, Epsom.*

AGRICULTURAL IMPROVEMENTS.

(Continued from page 366.)

With regard to the pecuniary relation of landlord and tenant, I shall endeavour to show that long leases and a Corn-rent (that is, the value of so many bushels of Wheat at the current price of the day) are essentially beneficial to both landlord and tenant, as well as to the country at large. Under this system landlord and tenant have but one common interest—they rise or fall together. The present custom of fixed money-rents acts alternately most injuriously on both. An unexpected war may find a tenant benefiting by an enormous price; whilst his landlord has only his four per cent., reduced, in fact, to two per cent., by all commodities having risen to war prices.

On the other hand, a tenant hires on a war lease—a sudden peace makes him bankrupt by the violent reaction; and still his landlord must let his farm at peace prices, whilst he was deprived of war benefits. The landlord is evidently the greatest sufferer, and should hasten to amend so unfair and so ruinous a system. The want of a well-founded code of rules for agricultural improvement is much felt. At present each individual claims for his own plan the palm of excellence. This should no longer be. Our Royal Agricultural Society, to which every landowner and farmer should belong, has already effected vast good; but still greater remains to be done. They should have extensive model farms, with schools and libraries attached. There should be shown, after patient investigation, the most perfect and certain modes of drainage, irrigation, and warping; the most complete, durable, and economical arrangement of buildings; the most advantageous mode of tillage and course of crops; the greatest economy of manure and labour; the minimum of seed and maximum of distance in sowing; the stage of ripeness at which grain should be harvested; the effect of steeping seeds in manures; the most profitable mode of housing and feeding stock, and the advantages of removing all trees and fences. When all these national and important subjects are accurately ascertained by a competent but limited board of paid and responsible directors, deciding regardless of personal considerations, then let a code of unerring rules be promulgated and enforced with the full weight and sanction of the Society, as a guide and beacon to the doubtful wanderer in search of agricultural knowledge, who, eager to avoid the shoals of error, is now distracted by multitudinous and conflicting opinions.

Chemistry and mechanism will, no doubt, daily lend new aids to Agriculture; but the points I have mentioned must always form the unalterable basis of our agricultural structure.

Much is being said about how we are to pay for our foreign Corn importations, whether in goods or in money. This is not our affair at all—we are purchasers. If you will have foreign Corn, Flax, and other things, that you might profitably produce at home, you must pay for them; and the seller (the foreigner) will not allow you to dictate to him how he shall take his payment, whether in goods or in money; that is his affair—not yours. The whole question of foreign Corn importation is, to my mind, trivial and insignificant, as compared with the importance of national agricultural improvement; and I hope to see the latter occupy the minds and speeches of our statesmen and orators to the exclusion of the former.

Let us grow Corn instead of timber, fences, and rubbish: we can do better without one than the other. I am told, "We must have timber! What should we do in case of war?" I answer, "How do we get our tea, coffee, wine, and every other foreign article in time of war?" So long as we have money to buy, and hearts of oak to defend and convoy our purchases, Old England can never feel a want, nor want a market to buy in. Besides, what a gross folly it is to grow our own timber in Corn-fields, at a cost of four shillings a foot (I am sure it costs more), when we can import it at one-third the price.

Some gentlemen think the removal of fences and throwing open the country would be detrimental to game. This is contrary to the proof: wherever land is thoroughly drained and the Turnip culture introduced, so surely will game (if protected) thrive and increase. Wet and pasty undrained land is inimical to game—particularly in a wet season.

A great error amongst farmers is the desire to grasp a large quantity of land, instead of concentrating their capital by improvement in a smaller compass. One of the important results of my suggestions as to valuing and making improvements, would be, that instead of 6*l.* to 8*l.* per acre being (as it is now on an average) a sufficient tenant's capital, double that amount would be required, as on my farm. This alone would find employment for considerably more than one hundred millions of additional capital, so that, in fact, when we had disposed of all our foreign bonds and securities, I doubt if we should have near money enough to carry out entirely my practical scale of improvements, except slowly and gradually.

Let Agriculture form an honourable portion of our general education—why should it not? Let Tull and Tusser range side by side with Homer and Virgil. Then would our nobility and gentry be independent of incompetent or dishonest stewards and land-agents, and be able to appreciate those of a more worthy character. Agricultural education and apprenticeships for our young farmers are indispensable. Why should there not be as much uniformity in growing a sack of Corn as in manufacturing a piece of cotton, or a hat or coat? How many a worthy person, retiring from the toils and turmoils of a busy city to enjoy the tranquil peace of agri-

culture, remove the want of agricultural knowledge!—often are his hopes and intentions frustrated and his property diminished by interested or erroneous advice, of which, till too late, he cannot judge. When I see landlords making returns of rent (in my opinion an injudicious operation), I think how much better would it be to present their tenants with agricultural libraries. Farmers, from the very nature of their occupation, and their isolated position, are seldom able to travel from county to county in search of facts; but how readily is a multitude of agricultural experiments and experience brought to their fireside by a selection of good and practical books! Some may say, "Oh, farmers are too prejudiced to read." Experience has taught me the contrary. Bring them the book, they will keenly, anxiously, and with sound sense, scrutinise all that concerns their pecuniary welfare. Reason tells us that the farmer, born, bred, and mixing with others of precisely the same way of acting and thinking as himself, cannot be expected to have so expanded a mind as a manufacturer or trader, who is daily in contact with strangers from every corner of the globe.

It is to be feared, too, that jealous landlords form too low an estimate of a farmer's character, and consider his success and elevation as degrading them—as if his gains were their loss. Let us hope this feeling will gradually give way to a better, and that a farmer who follows the hounds, and dresses and acts respectably, will be considered quite as likely to farm well and make as good a member of society as one who imitates in every respect one of his labourers.

Where individuals are desirous of improving their own estates without disbursing capital, I know of no plan so good as allowing the tenant annually a certain sum out of his rent for improvements, taking care that they are really beneficial, which is very easily ascertained and arranged: generally speaking, tenants would most readily contribute their share, particularly in the matter of drainage.

The national health is deeply concerned in agricultural improvement, for it is notorious that perfect drainage of land and buildings insures the absence of agues, fevers, and other complaints, that are sad drawbacks to the personal welfare and pecuniary comforts of our agricultural population, to say nothing of the importance, in a national point of view, of having a hardy, healthful race in lieu of a debilitated and vitiated population. The mind and the body are too sympathetic to be uninfluenced by each other. Humanity, policy, and self-interest, then, call loudly on us to unite for the worthy purpose of national agricultural improvement.—*I. J. Mechi*, 4, *Leadenhall street*.

P.S. I shall publish annually a faithful and correct debtor and creditor account of my farm, valuing the crops and stock at one uniform average price (the average price in the county of Essex for the last fourteen years). This will prevent confusion, and admit of a correct comparison of one year with another. The quantity produced, and the cost of producing, will be the principal and most interesting considerations.

ON THE APPLICATION OF MANURES.

(*Continued from page* 497.)

Now, the improvement of the plants from repeated hoeings is indisputable; that it is not promoted through the roots is, I think, probable (provable), for the hoeings are not deep enough, the earth is not moved by them to a sufficient depth to renew the decay and form a fresh portion of carbonic acid, about the roots of the plants. How, then, do they operate this improvement? I say, by letting loose the effluviæ of the decaying animal and vegetable matters contained in the soil, to the depth, or to a very little more than the depth to which their loosenings extend, (it is evident to the senses that such effluviæ do escape) and by these effluviæ being absorbed by the leaves, and not by the roots.

The same deduction may be drawn from all our field operations. In the month of February or March, if, either from the poverty of the soil or weak growth of the plants, it appears requisite, many will top-dress their Wheat crops. It is usual to top-dress Red Clover (a tap-rooted plant, and therefore one plunging deeply into the soil) between the cuttings, with a view of increasing the immediate after-growth; Grasses are top-dressed. In Ireland, where they know how to grow as heavy a crop of Potatoes, as well as to eat them, as anywhere else, a very evident improvement takes place immediately after shovelling (moulding) the beds; on the west coast of Donegal they very generally are at the trouble of carrying manure in baskets, and laying a little bit at the butt of each plant, previous to shovelling (moulding the second time) the beds, the plants being at this time from two to six inches high. They state that this is attended with very beneficial effects; that it keeps the stalks green and growing longer than they would be without this application; these people will also dibble in their Potato sets, and delay manuring them till they are breaking ground, and they say they are less weedy and more productive than if manured earlier.* In all these operations it is impossible to attribute the results to any action on the roots; they must be attributed to the absorption of effluviæ disengaged from decaying animal and vegetable matters by the leaves of the plants.

In 1831, at Killybegs, I transplanted Potato sets from a hot-bed into drills in a field; the operation (as will always be the case when labourers are entrusted with novel, and to them foolish work) was so indifferently performed that the manure was scarcely covered, yet the crop was an excessively heavy one, and the Potatoes very large. Three years ago I planted a small patch of Potatoes in rows, the sets being planted in rows six or eight inches deep. I spread short stable dung on the surface, with the intention of digging it into the ground; this was neglected, and I believe they were not even hoed, or at most not more than once; the crop was so very heavy, under a treatment so widely at variance with received opinions, that it led me to suspect that the plants had received nourishment through their leaves from the effluvia of the dung spread on the surface.

A few days ago I got into conversation with a tenant of Mr. Greville's, near this town; he was ploughing an Oat stubble for a second crop of Oats; I inquired, would he not have had a better crop had he sown it in February or March? He said no; that Oats sown on poor land, in the "darks" of April (when there was no moonlight), were a better crop than if sown before the natural heat came into the ground; (on the west coast of Donegal, as well as in many parts of Ireland, April is considered a good seed-time for Oats)—that if sown earlier it would perish the plants—meaning that the plants in their earlier growth would be sickly, (and if we admit the efficacy of steeping seeds, the sickliness of the young plant must upon the same principle be injurious to their future growth); and that the later sowing would overtake it, and prove a heavier crop at harvest; this is the general opinion of the smaller holders of land in Ireland, and is the result of an experience which we have no right to despise. I have for 25 years heard this opinion expressed, and have hitherto contemned it as that of prejudiced ignorance and a lazy excuse. We are too prone in our self-sufficiency to taunt with their failings the poorer classes of Irish, and probably with as little reason as in the present instance. To what, then, are we to attribute this fact? and fact it is—but that in poor ground, in the early season, the seed germinates so slowly that the gases let loose by the ploughing escape, and the surface becomes crusted, so as to prevent the escape of any that remain before the germ has reached the surface; when it does get above ground the young leaves are therefore starved. When the leaves of young plants look sickly and yellow, which is, I think, falsely attributed to the wire-worm, it is common to roll the ground; this breaks the crust (not crushes the worm) and the nourishment the leaves consequently receive from the escape of gases restore them to health.

The Editor of "Liebig's Chemistry of Agriculture," on the authority of "Davis's History of China," says—"In the case of everything except Rice, the Chinese seem to manure the plant itself, rather than the soil;" and Liebig himself says, "How infinitely inferior is the agriculture of Europe to that of China!" And again he says, "The agriculture of their country is the most perfect in the world." In speaking of guano he also says, "Thus in Arica, where so much Pepper (Capsicum baccatum), is cultivated, each plant is manured three times: first, upon the appearance of the roots; second, upon that of the leaves; and lastly, upon the formation of the fruit (Humboldt); from this it will be observed, that the Peruvians follow the plan of the Chinese in manuring the plant rather than the soil." Yet Liebig always supposes that plants are fed by the roots, and is even at the pains of bringing ammonia from the air, with every shower, to supply them with azote, which he states to be washed down to them with the rain-water, and adduces what I must think a very questionable proof; he says, "In the year 1834 I was engaged with Dr. Willrand, Professor of Botany in the University of Giessen, in an investigation respecting the quantity of sugar contained in different varieties of Maple-trees which grew upon soils which were not manured. We obtained crystallised sugars from all, by simply evaporating their juices, without the addition of any foreign substance; and we unexpectedly made the observation that a great quantity of ammonia was emitted from this juice when mixed with lime, and also from the sugar itself, during its refinement." Now, if the sugar had been obtained from the ascending sap, this would be a very sufficient proof that the ammonia had been imbibed by the roots from the ground; but as there can be no doubt that it is from the descending, and, if you will, elaborated sap, that the sugar was obtained, it might be asserted with more probability that the ammonia had been sucked in by the leaves; and it does appear more agreeable to the evanescent nature of ammonia, that instead of descending into the depths of the earth to seek the roots, it should, when the shower which had lodged it on the surface had ceased, with the first blink of sunshine ascend into the air, and, on approaching the leaves, be sucked in by their pores; and were it not even so volatile, Liebig himself would admit that the evaporating moisture would communicate a similar state to it. Now, we find precisely the most rapid growth of plants is in the spring months, when the showers are not so heavy or continuous as to sink into the earth, but are succeeded instantly by a hot sun; and this is called proverbially growing weather.

On the same principle I can well account for the effect which is said to attend the steeping of seeds in chemical solutions, and the success which their experience has taught the Chinese to reckon on from steeping their seeds in liquid manure until germination begins; the seeds absorb a quantity of concentrated gases, which are gradually let loose to feed the shooting germs; these also break through the surface and attain some growth before all the gases have escaped, which have been set in motion on the moving of the earth in the sowing of the seed; the plant thus acquires an early robustness, which, under ordinary circumstances, maintains its superiority through its whole growth over plants which have not been so treated.—*T. M. G., Revenue Police, Granard, Ireland.*

* In Ireland, the small farmers rarely drill their Potatoes, they generally plant them in beds from three to five feet wide, according to the depth of the soil, allowing the necessary earth for covering the Beds; the sets are either laid on the surface or dibbled in, the manure spread on the surface and covered from the furrows; where the plants appear, or before they are six inches high, the beds are again covered, and it is reckoned good husbandry to give them a third covering from the furrows.

SKETCHES OF EAST LOTHIAN HUSBANDRY.

In describing the different modes of ploughing, I shall first suppose the land to be nearly level, as is usually the case after summer fallow, or after the separation of drilled crops from the ground. As the furrows which divided the original ridges are then nearly or altogether obliterated, the foreman, provided with three or more poles of a known length, marks off the field in the usual manner, into parallel and equal divisions, corresponding in size to the intended ridges. The form of the ridges, and the situation of the intermediate furrows, are carefully preserved from year to year, especially when the former are much rounded or elevated in the crown, as is the invariable custom in strong retentive soils. The position of the furrows are never altered except in situations where the land happens to be very dry and light. In ridging up such of the fields as had been recently furrow-drained, much care is taken to have the furrows directly over the drains, in order to facilitate the escape of surface-water into them. It will be recollected, that drains are now invariably made in the furrows, either in each, or in every alternate one, as may be found necessary or convenient at the time. When the furrows are obliterated or not distinctly visible, from the effects of subsequent tillage, the situation of each drain is accurately ascertained by digging with a spade until the tiles or stones employed in filling it are reached. The feirings, which afterwards become the crowns of the ridges, are then drawn midway between the drains. In ridging up land for Wheat or other Corn crops, after having been nearly levelled down while undergoing the process of summer fallow, or the operations preparatory for green crops, the method of ploughing termed gathering, is that generally adopted in heavy soils, as giving to the ridges a greater degree of curvature than what can be done in any other way. Besides the common mode of marking off land with the aid of poles, before ploughing it into ridges, the following simple method is practised in some parts of the county, and in Berwickshire, for the same purpose:—A stout pole, called a *marker*, equal in length to the breadth of the intended ridge, is fixed to the plough at right angles to the line of draught; one end of it is attached by a simple contrivance to the beam a little before the coulter, while the other projects either towards the right or left-hand side of the ploughman, as may be required, and is kept steadily in its place by means of a rope passing from the outer end to the collar of the horse, on the same side as that to which the pole projects. A small coulter or *skirrop-tine* is attached perpendicularly to the outer extremity of the pole, which traces a mark or rut on the ground as the plough moves onward, parallel to the line of draught, and sufficiently visible to serve as a guide for the ploughman in drawing his next line. When arrived at the headland, he alters the pole to the side opposite to that on which it was last, proceeds with his plough along the track newly made by the marker, and in doing so, traces another track with the pole exactly parallel to the last. In this manner the whole field is gone over. By adopting this device, it is only necessary to mark off the first feiring with the aid of poles in the usual manner, at the proper distance from that side of the field parallel to which it is intended to run the ridges, as the marker traces the line in which the next and every succeeding feiring is to be drawn. This plan has been found to answer very well on light friable soils, and in situations where, on account of the inequalities of the surface, a considerable number of poles would be required in laying off ridges in the ordinary way.

Much pains are everywhere taken by the ploughmen, in forming these ridges, to give them a uniform degree of curvature, and to have the furrows as straight, shallow, and narrow as possible, as the land is then usually sown out with Clover and Grass-seeds. The first two furrow-slices around each side of the feiring, or crown, are ploughed shallow; the next few something deeper, and the remainder gradually lessening in depth towards the furrow; the ridge thus obtains a regular degree of rotundity or elevation. In ploughing the last, or hiating furrow-slice of a ridge in strong wet soils, one of the horses is usually unyoked from the plough, in order to prevent any injury to the land from treading upon it. Sometimes, when the soil is of a very stiff nature, the horses are yoked one before the other while finishing the ridge, both walking in the furrow. No footmarks are permitted to appear on the land after being ploughed.

When land is thus formed into ridges, it is afterwards ploughed, without marking them off anew until the furrows are effaced by subsequent tillage. In ploughing *lea* or Grass lands, the system of ploughing, termed *casting*, is that universally practised. When this mode is pursued, the feirings are always made in the furrows, and in a manner somewhat different from that adopted in the case of gathering. In casting ridges the assistance of poles is entirely dispensed with, a commencement being made by taking a slice from the left hand side of the furrow in which the feiring is to be made; small-furrow slices are next ploughed from each of the adjoining ridges—one resting upon that first ploughed, and the other falling into and occupying the situation of the original furrow; two slices of ordinary dimensions are then ploughed up to these from each ridge after

which the plough is made to pass over the space occupied by the old furrow, in order to clear a channel for the free passage of water; but where the land is dry and light, not being so liable to suffer from the retention of moisture as strong clays, this last operation is frequently dispensed with. The two ridges are then ploughed together, by turning the horses at the headlands to the right-about; that is, the ridges are hupped in, the successive furrow-slices of both ridges inclining towards the furrow between them. Another feiring is made, *after concluding* three ridges, in the fourth furrow from that in which the last one had been drawn, and the adjoining ridges ploughed together as before. Two unploughed ridges are thus left between the four already accomplished, in ploughing which, the ploughman begins at that side of either ridge adjacent to the ploughed ones, lays in a small slice directly over the former furrow, and does the same in returning along the other ridge; two furrow-slices of the regular size are then ploughed up to these, and the plough made to pass through as before, not allowing the irons to enter the soil. These two ridges are then completed by turning the horses at the headlands from right to left, that is, they are winded out, the operation concluding at the intermediate furrow, which, hence, becomes what is termed an open furrow. By this manner of ploughing, which is now the most generally practised on all kinds of land throughout East Lothian, the form of the ridges and the situation of the original furrows are preserved. All the furrow-slices of each two adjoining ridges incline in the same direction, while those of the next pair lie in the contrary way.

The principal advantages resulting from this mode of ploughing arise from the small number of open furrows thereby occasioned, only every fourth being an open one; and to any person accustomed to inspect Corn-fields, particularly in droughty summers, who compares the stunted appearance of the crop, in and about those deep open furrows, with the luxuriance and freshness of that in the close furrows, as the others are called, the utility of diminishing the number of the former will be abundantly evident. To lessen their number as far as can be conveniently done, eight ridges, instead of four, are frequently taken in at once—the feirings and open furrows occurring only at intervals of eight ridges, four of the latter being hupped in and four winded out. But in this case, where the field is not of considerable length, a loss of time in so frequently turning at the headlands is unavoidably occasioned. When the field, or ridge-lengths, to be ploughed happen, therefore, to be short, only four ridges are taken in at once; but when of considerable length, eight ridges are ploughed with one feiring. This mode of ploughing—casting the ridges—has been found peculiarly adapted to strong clayey soils retentive of moisture, in which the ridges had been raised by previous ploughings.

The only material imperfection arising from casting is, that the open furrows, from being made in the situation of the previous ones, are necessarily deeper and barer of earth than when, as in the case of crown-and-furrow ploughing, they occur in the middle of the ridge. To obviate this defect, either of the two following plans is sometimes adopted in ploughing lea:—Instead of four or eight ridges, five or nine are taken in together; the feiring is then made either on the crown of a ridge or in a furrow; if on the crown, that ridge and the two at either side (supposing nine ridges taken in), are ploughed together as before, and the others winded out, concluding in a furrow; but when, as is most generally done, the feiring is made in the open furrow, four ridges are hupped in and five winded out, terminating at the crown of the central ridge, which is thereby cloven into halves. When next ploughed, this and the four adjoining ridges are gathered, the other four winded out, and all restored to their original position.

Whilst the ploughing of the lea is being carried on, all the skill, taste, and anxiety of the ploughman are brought into action. Each man has a certain number of ridges to himself, and when several experienced ploughmen, all nearly of a match in point of skill, are working together, the greatest competition prevails amongst them. The ploughs and their irons are always kept in the best working order, and every exertion is made by each man in endeavouring to execute his work in a style superior to that of his neighbours. To excel in straightness and regularity, in cutting a good *shoulder*,* and in packing the furrow-slice closely together, is the great ambition of every good ploughman.—*T. Sullivan.*

Home Correspondence.

Guano.—Contracts for Ichaboe African Guano have been signed to be delivered from March to middle of May, 1845, at 6*l.* 6*s.* per ton, ex ship, port of Liverpool. The last news from the Island of Ichaboe was that 100 ships were then waiting their turn to load; and in order to give dispatch to the vessels waiting their turn to take in their cargoes, the crews of other ships were assisting in loading the vessels in berth. It is also said by some, that in 12 months the stock of guano in Ichaboe Island will be exhausted; but it is said there are other islands equally valuable. If that was the case, why should so many ships accumulate and wait so patiently their turn to be laden? The supply of African guano is very liberal; and although a week back the trade was very dull, the late rains have given great encouragement for the sale. It is also calculated by many importers that guano will be bought on better terms the next three months, than will happen again for years; for the number of ships on their passage to load at Ichaboe Island, and those returning laden, will overstock the market, as the season will be over before they can arrive.—*W. H. Harwood, Liverpool.*

Compost-heaps.—I have been in the habit of paring the sides of roads, ditches, &c. for the last 30 years, and have found much benefit from laying it up for compost and trenching it into the soil. If farmers and cottagers would follow my example, it would be a great benefit to them. If a clause was inserted in the Turnpike Act, to force all occupiers of land &c. to cut down all tall-growing weeds, such as Docks, Thistles, Nettles, &c. as far as their lands and premises extended, twice in the summer—say middle of June and middle of August—it would be of much benefit to the country at large.—*F. X. O.*

Bran.—"H. Lawson," (p. 421,) will find in the first volume of Boussingaults "Economie Rural," p. 464, that bran consists of gluten and albumen 20. and gum, &c., 28.10, fatty matter 5.5, woody matter and ashes 45.7., total 100.—*C. J. Lancaster.*

Vitality of Seed.—With reference to Mr. Bernays's communication in a late *Gazette*, it may be in your recollection that a few years ago, every other person one met was swallowing quantities of Mustard-seed to promote digestion—the whole of which passed off without any other perceptible change than that of being a little swollen, and thus, perhaps, made more ready to germinate. Why, then, may we not presume that the seeds of weeds pass equally unaltered through the bodies of many animals? A writer in a recent Number of the *Gazette*, stated that one cwt. of salt would destroy all the seeds in a ton of dung. Now if this be the fact, may we not first destroy the seeds by mixing salt with the manure-heap, and then, after a time, treating it with sulphuric acid? We should thus get rid of our weeds; and then by the reaction of the salt, sulphuric acid, and ammonia, we should get the fixed salts of sulphate of soda and muriate of ammonia. See Solly's "Rural Chemistry," page 41.—*Agricola.* [Our correspondent's suggestion is probably correct so far as all animals that do not chew the cud are concerned. We have heard that one of the quickest ways of obtaining young hawthorn plants, is to feed geese on the haws, and sow their manure. In all except ruminating animals, if seed given in their food be not crushed in the act of mastication, it will rarely be injured by the process of digestion.]

Liquid Manure.—When the weather is wet, I propose carting the liquid at once upon fallow ground; having at this time a very good crop of Potatoes growing on the very poorest piece of ground about me, entirely owing to having in the winter carted out upon it the overflowings of my farm-yard.—*A Beginner.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

JUDGING from the numbers and quality of the articles—Implements and Live-stock—exhibited at Southampton during the past week, as well as from the number of visitors attracted thither from all parts of the kingdom, we may believe that the late meeting of this Society may vie with any of its predecessors in point either of interest or usefulness.

In reporting the proceedings of the past week, we shall proceed in the order of time, that being a simple arrangement, and one more likely than any other to present an intelligible statement to those of our readers who have been absent.

The Judges of Implements having been occupied during Monday in ascertaining their merits, by test as well as examination, it was not till Tuesday morning that the public were admitted to the Show-yard. In the following imperfect description of what was there exhibited, a comparison has first been drawn between the Exhibition of this year and that of last, in order to which advantage has been taken of the report by the Society's Judges of the Derby meeting in a late vol. of the Journal.

The following paragraphs retain their truth. We apply them to the Exhibition of the present year:—

"The Judges have again the gratification of recording that, in number, variety, and perfection, this Exhibition greatly excelled all that preceded it. Perhaps a more substantive proof of the progress made in this great department of the Society's solicitude cannot be adduced, than that the exhibitors annually outgrow enlarged show-yards, and intreat more stringent and exact trials of their implements. It is thought that the following analysis of the contents of the show-yard may not only serve to convey a just idea, but be a proper historical record, of the magnitude and variety of the collection; and that it may tend to confirm the Council in their desire to render the catalogue of implements a perfect register of the Exhibition. As such, the catalogue would become not merely a momentary guide, but a useful annual work for native and foreign purchasers to consult, after as well as during the Show. The analysis now given, as prefatory to the award of premiums, and usual short account of some of the implements, presents a concise classification of the machinery employed in various departments of British husbandry; and it may possibly aid the Council in selecting the objects or classes which more particularly demand future encouragement by the Society. As a digest of the nature, number, and value of the implements in habitual use by farmers, it cannot fail to impress the mind with the importance of agricultural mechanism as a branch of national industry, and as consuming an immense amount of native materials."

We have made use of this analytic statement of the implements then at Derby, and, as follows, we have added a column, giving as nearly as a necessarily hurried examination would permit, a corresponding analysis of this year's Exhibition. It may be mentioned in proof of the accuracy of the first sentence quoted above, as applied to the Southampton Show, that the money value of the implements exhibited, was upward of 9200*l.*, while that of those shown at Derby amounted to 7400*l.* only.

ANALYSIS OF THE EXHIBITION.	No. of Articles Exhibited at Derby.	Southampton.
TILLAGE IMPLEMENTS.—PLOUGHS.		
Swing, moulding and ridging included	48*	51
One-wheel	15	27
Two-wheel, double-furrow included	55	56
Subsoil, common	3	..
Ditto, various	6	10
Sub-pulverisers	4	..
DRto and Surface-ploughs	3	..
Ditto and hoes	2	..
Stubble and paring	4	6
Water-furrow clearing, or Boat-plough	1	..
Draining	3	..
Drill-ploughs, one-row	2	..
Ditto, three-row	1	4
HARROWS.	—148	—162
Common, and improved	19	..
Drag, and scarifying	2	..
Extirpating	1	..
Lever	2	..
Revolving and sowing	1	..
Ditto, vertically	1	..
Ditto, horizontally	1	..
Chain-web	3	..
Folding	1	..
	—31	—28
SCARIFIERS.—Cultivators, grubbers, scufflers, included	25	26
CLOD-CRUSHERS.—Various	7	13
ROLLERS.—Various, cast and wrought iron	12	16
COUCH-RAKES.—Various	4	5
DRILLING, SOWING, MANURING, AND HOEING MACHINES.		
DRILLS AND PRESSERS.		
Drills for corn and seed, with manure	14	..
Ditto, ditto without manure	1	..
Ditto for Turnip-seed with manure	10	..
Ditto ditto, without manure	1	..
Ditto ditto, with manure-cart	1	..
Ditto for seeds, with manure	3	..
Ditto ditto, without manure	10	73
Ditto and Pressers, with manure	6	..
Ditto ditto, without manure	4	..
Ditto for solid manures only	1	..
Ditto for liquid manures only	1	..
Pressers, without drills	2	..
Seed-sowing Barrow, without manure	1	..
Drill-ploughs—(see PLOUGHS.)	—51	—73
DIBBLERS.		
Five-row horse dibbling machine and sower	1	..
Two row ditto ditto	1	..
Two-row hand or horse dibbling wheel	1	..
One-row hand ditto	1	..
HORSE-HOES.—Broad, narrow, and variously contrived, to suit drilled crops	—4 20	—8 23
HARVESTING MACHINES.		
HAY-MAKING.—Tedding machines	4	..
HORSE-RAKES:—Hay, corn, and stubble	7	13
Corn Gatherer	..	1
	—11	—14
BARN MACHINERY.		
HORSE-ENGINES:—Various powers, travelling and fixed	7	several.
STEAM-ENGINES.		
Travelling, for threshing, &c.	3	..
Applied to Corn-mills, &c.	3	..
	— 6	— 4
THRESHING-MACHINES.		
Driven by hand	4	7
Driven by horse or steam power	11	22
Threshing floor	..	3
	—15	—32
WINNOWING, CORN-CLEANING, AND BARLEY-HUMMELLING.		
Various	20	24
CRUSHING AND SPLITTING MILLS.		
Various	36	48
CORN AND MEAL MILLS.		
Metallic hand Corn-mills	8	..
French burr ditto	5	..
Grey stone ditto	1	..
Mill, with two-horse power engine	1	..
Mills for animal, engine, or other power	4	..
Metallic meal-mills	2	..
Hand dressing-machine	1	..
	—20	—19
CHAFF-CUTTERS.		
Various, adapted to manual, animal and steam-power	31	36
CAKE-CRUSHERS.		
Various	14	15
CORN WEIGHERS AND METERS.		
Weigher	1	..
Meter, self-registering	1	2
	— 2	— 2
FIELD, FOLD, AND YARD MACHINERY.		
TURNIP-CUTTERS.		
Hand and portable	11	..
Attached to cart	1	..
	—12	— 9
ROOT-GRATING, AND SQUEEZING MACHINES.		
Graters	8	..
Cider-mill, Turnip, and Potato squeezer	1	..
POTATO-WASHERS.	— 9	— 2
Various	2	2
STEAMING APPARATUS.		
Various	5	2
FEEDING APPARATUS.		
Consisting of iron pig-troughs, pens, cow and sheep cribs on wheels, mangers, racks, &c.	..	..
Fodder preserver	..	..
WEIGHING MACHINES.		
For carts, cattle, sheep, &c.	4	14
FIRE-ENGINES, &c.		
Fire-engine, with irrigator, attached to steam-engine	1	..
Ditto, hand and portable	4	..
Garden-engines, various	6	..
	—11	—14

* This phrase, though well understood by ploughmen, is not easily explained with precision. It means a particular form or appearance presented by the furrow-slice after being turned over. The advantages of ploughing Grass lands with a good shoulder are, that the surface is enabled to resist the winter rains, and afterwards to produce a proper covering for the seeds.

ANALYSIS OF THE EXHIBITION.

	No. of Articles Exhibited at Derby.	Southampton.
Stack-Yard.		
Proposed substitutes for thatch	8	4
Rick ventilator	1	2
Hay sample borer; assortments of rick-cloths, iron rick-stools, and frames, &c.	..	4
Rickstands	6	10
Sundries.		
Iron Barrow for heating and transporting tar	1	
Machine for breaking stones	1	
Fan-blower, for out or in-door forge	1	
Iron Field gates	3	
Assortments of iron Hurdles, fencing, Seats, Barrows, Trucks, &c. Saw-machines, Screw-Jacks, Cranes, Pumps, Garden-tools, &c.	..	Many lots.
Weed and Bush Extractor, assortment	..	
	— 6	
AGRICULTURAL CARRIAGES, HARNESS, AND GEAR.		
Waggons, Carts, &c.		
Waggons, without springs	7	..
,, on springs	3	..
Harvest Waggon, on springs	1	..
Market and Corn delivery carriage, on springs	1	..
Waggon, formed of two combined carts	1	..
Carts, without springs	10	..
,, for general and harvest work, on springs	3	..
,, for harvest, without springs	5	..

AWARD OF PREMIUMS.

The following is the Award of Prizes for Implements, so far as it has yet been published.

	Premiums.
I.—Ploughs.	
To Messrs. J. R. and A. Ransome, Ipswich, for their heavy land Plough	10*l.* and Silver Medal.
To Messrs. J. R. and A. Ransome, Ipswich, for their light land Plough	10*l.* and Silver Medal.
To Messrs. J. R. and A. Ransome, Ipswich, for Lowcock's patent Plough	5*l.*
To Mr. John Bruce, Stratford-on-Avon, for his skim Plough	5*l.*
II.—Drills.	
To Mr. R. Garrett, Saxmundham, for his Drill for general purposes	20*l.* and Silver Medal.
To Mr. J. Smyth, Yoxford, for his Turnip and Manure Drill	10*l.* and Silver Medal.
III.—Scarifiers, &c.	
To the Earl of Ducie, Dursley, for his Cultivator	10*l.* and Silver Medal.
To Mr. D. Harkes, Knutsford, for his expanding Horse-hoe	5*l.*
To Mr. Garrett, Saxmundham, for his patent Horse-hoe	Siver Medal.
To Messrs. Saunders, Williams, and Taylor, Bedford, for their patent Harrows	5*l.*
IV.—Chaff-cutters, &c.	
To the Earl of Ducie, Dursley, for his Chaff-cutter	10*l.* and Silver Medal.
To Mr. Gardner, Banbury, for his Turnip-cutter	5*l.*
To Mr. Hornsby, Grantham, for his Cake-crusher	5*l.*
V.—Sundries.	
To Mr. D. Coombs, Barford, for his Oxfordshire Waggon	15*l.* and Silver Medal.
To Mr. Stratton, Bristol, for his Harvest cart	Silver Medal.
To Ditto, for his Agricultural spring-cart	Silver Medal.
To the Earl of Ducie, Dursley, for his Richmond Cart	Silver Medal.
To Mr. Stratton, Bristol, for his Water-cart	5*l.*
To Mr. Croskill, for his Clod-crusher	20*l.*
To Mr. Hornsby, Grantham, for his Drill-presser	10*l.* and Silver Medal.
To Mr. John Reid, Regent Circus, Piccadilly, for his subsoil Pulveriser	10*l.*
To Mr. Cooch, Northampton, for his Barley hummeller	Silver Medal.
To Mr. Stratton, Bristol, for Gingell's Cheese-press	Silver Medal.
To Mr. Harkes, Knutsford, for his Churn	5*l.*
To Messrs. J. Hall and Co., Cambridge, for Constable's Trefoil and Clover-drawing machine	5*l.*
To Mr. J. Knight, Maidstone, for his patent Hopkiln	5*l.*
To Mr. Stratton, Bristol, for Fry's Bone-breaker	2*l.*
To Mr. Deane, Birmingham, for his Hand-mill	Silver Medal.

Award of Premiums—continued.

To Mr. Hill, Dudley, for his Cow-crib	5*l.*
To Mr. Garrett, Saxmundham, for Springall's Rack-stand	Silver Medal.
To Mr. Hill, Dudley, for his Sheep-fence	Silver Medal.
To the Earl of Ducie, Dursley, for Clyburn's Screw spanner	Silver Medal.
To Mr. Pearce, Andover, for his Rack-band Tug	Silver Medal.
To Messrs. Tasker and Fowle, for their machinery for drawing water	Silver Medal.
To Mr. J. Reid, Regent Circus, Piccadilly, for his Fire-engine	5*l.*
To Messrs. Ransome, Ipswich, for their Horse-works with Bean-splitter, Chaff-cutter, and Linseed crusher	30*l.*
To Mr. Cambridge, Devizes, for his Steam-engine	5*l.*
To Messrs. Ransome, Ipswich, for their hand-drain, tile, and pipe machine	20*l.* and Silver Medal.

Rather than give a mere list of implements exhibited by the various machine-makers, which would not interest the generality of our readers, we have in the following statement singled out a few deserving of particular notice, enlarging at some length on their merits.

Ploughs.—We cannot give anything like a description of the very many implements of this class exhibited this year. The following remarks by the Judges, extracted from the Report of the Derby Show, apply equally to that at Southampton:—"They would particularise, as worthy of high commendation, those produced from the manufactory of Messrs. Ransome, composed entirely of iron and steel. The beams of these ploughs are constructed on the *truss* principle, which, though novel in its application to the plough, has long been appreciated by mechanics as possessing the greatest stiffness combined with lightness. It is this consideration which has induced those makers to abandon the use of wood, heretofore chiefly used by them for this part of the plough in preference to a beam of solid metal. The structure of their improved iron beam is such as to destroy lateral vibration, particularly at its root or junction with the body of the plough; it admits also of a neat and powerful fixing, as well as ready adjustment of the coulter. Tremor in mechanism is well known to consume power uselessly; and in the case of the plough, vibration in the beam, though it be insensible to the eye, renders the guidance of the implement more difficult, and its work less exact. The circumstance of increased stiffness attending mere weight of matter, may have been one cause why the heavier ploughs have not unfrequently been found to require less force of draught than lighter ones for an equal weight of soil moved; but stiffness is not incompatible with lightness, and a diminution in the weight of an implement, when perfect action is otherwise secured, must be attended with economy of power, or, what is the same thing, with a diminution of resistance, whence truer work results. It is also important that the stilts or handles should be stiff enough to transfer the effort of the holder to the body of a plough, with the least expenditure of his strength; for, the easier its guidance, the greater will be the certainty of the labourer's attention to his business. This property has also received the care of Messrs. Ransome, and, together with the simple means applied for adjusting and replacing the mould-boards, shares, and wearing parts of the various ploughs exhibited by them, testified to the thought and ability bestowed on the most minute details of an implement which still maintains its claim to be the most indispensable, as it was probably the earliest invented, auxiliary to human labour in tilling the soil."—Mr. Howard of Bedford, Messrs. Barrett and Exall of Reading, Messrs. Saunders and Williams of Bedford, and others, exhibited numerous implements in this class, with one, two, and without wheels. We select two, both of them turn-wrest Ploughs, as exhibiting much ingenuity. One of the best of this kind was exhibited by Mr. Comins of South Molton, Devon. We do not speak here of its efficacy as an agricultural implement, for we did not see it tested on the trial ground, but of the means of shifting the mould-board, share, and coulter at the land's end. This is all done by one simple operation: the implement has a double mould-board, so slightly curved as that each in succession answers the purpose of side-plate, while the other acts as turn-furrow. The under and upper side of the share are brought into action alternately, its edge being presented alternately right and left, according to the way the implement is working. The motions necessary to effect the change in the position of both mould-board and share, are obtained by shifting a lever, which rests on the handles, from one side of the Plough to another. This act gives the required half-revolution to the share, by means of a crank on a longitudinal shaft, lying in the body of the Plough, above the sole-plate to which the share is attached; and by means of a pinion upon this shaft working into rack-work, on a bar stretched between the mould-boards, this half-revolution at the same time effects the required alteration in the position of the turn-furrow.—The other Plough, that exhibited by Messrs. Ransome, named in the catalogue "Lowcock's Patent Plough," is also on the turn-wrest principle. Its body consists of two mould-boards, of a correctly-curved form, placed back to back, each with appropriate beam, share, and coulter. The two beams are connected by an iron rod, which runs the whole length of the implement, and along it the draught-bars and chains slide from one beam to the other when the horses turn at land's-ends. It will be seen that the plough does not turn; it is a completely double implement, either end working equally well. The two ploughs, of which, in fact, it consists, have handles which are common to each; and being hinged at the top of the implement, in the middle of its length, they are easily lifted over from one end to the other when necessary. In order, also, to shorten the implement, instead of having two complete mould-boards, back to back, the one is made to encroach, as it were, upon the other, so that the two would intersect, were it not that around the vertical line in which this intersection would take place a portion of a mould-board is made to rotate, one side of which fits, when in working position, to one mould-board, and the other to the other. The front curves of the mould-boards are counterparts of each other; while the hinder curves of the mould-boards are formed by a fly, which, turning on a centre, alternately presents the continuation of the curve of either the right or left mould-board, as required to be used. When the ploughman has completed the furrow turned to the right, he reverses the handles; at the same time the draught-chain, to which the horses are attached, is, by the act of their turning, carried on a rod to the opposite end of the plough. The fly on the mould-board, by its own pressure against the soil, assumes its correct position, and the implement is at once in order for turning the furrow to the left without further adjustment.—A premium of 5*l.* was awarded to a skim Plough, invented and manufactured by Mr. Bruce, of Teddington, Stratford-on-Avon. In addition to its similarity to the efficient implement exhibited by Mr. Hill, of Brierly Works, Dudley, which was rewarded at the Derby meeting, it possesses a very simple means of being raised or depressed in the ground, dependent for its action on a pressure applied to the handles.—A simple draining Plough, capable of cutting out a small drain, and laying the earth alongside of it, was exhibited by Mr. Harkes, of Mere, Knutsford, Cheshire.—Mr. Bruce exhibited a subsoil Plough, which was rewarded at Derby, and highly praised in the Report by the Judges of that meeting. The following description is extracted from the Derby report:—"The Show-yard contained implements having stirrers upon the plan of the Charlbury subsoil, *i. e.* affixed to the hinder part or heel of the plough. Mr. Bruce's contrivance is on a different, and it is thought a superior principle. He applies to the right hand side of his plough-beam, and about parallel with the point of the share, a frame containing two tines, adjustable as to width and depth, which, by means of a lever brought convenient to the ploughman, can be raised out of work at the land's-end, and set in again on the next bout with great readiness. The tines stand off from the beam so as to work to the depth of about 5 inches below the furrow-slice last turned, and thus loosen the soil previously trodden by the horses, leaving the slice also in no inconsiderable state of division. On trial, the action of the tines did not at all appear to derange that of the plough, or throw additional labour on the holder. The Judges have learned that this combination has been used and much approved by practical farmers in the inventor's neighbourhood. From observing the effect of this arrangement, it has been suggested to Mr. Bruce, that in certain soils, with the addition of Mason's knives, a very complete disintegration of the surface, as well as the loosening the subsoil, would be effected by the plough at one operation." In this instrument, as shown at Southampton, this suggestion has been attended to, probably, for we did not see it at work, with the best effect.

Scarifiers, Harrows, &c.—The Society's Prize of 10*l.* and a Silver Medal was awarded to the Earl of Ducie, for his seven-tined Uley Cultivator. This proved a most efficient implement in the trial-ground. In comparison with Biddle's Scarifier, of which several were exhibited by various makers, on the part of which Messrs. Ransome, of Ipswich, still contend that they manufacture the best scarifier, we think it possesses the advantages of a better and less-liable-to-choke arrangement of the teeth, and a better and more efficient form of the tooth as a stirrer and cleanser of the ground. Whether the means for raising and lowering the implement in the ground is practically inferior or superior to that adopted in Biddle's implement, we shall not venture to determine.—A parallel expanding Horse-hoe, exhibited by Messrs. Barrett and Exall, of Reading, presented a very simple adaptation of the principle of the parallel ruler. The advantage obtained in this case is the ability to employ curved teeth, which are far more efficient than those of the ordinary vertical form. This curved form cannot be used in implements having the ordinary radial method of widening, because in this case, if in any one position of the radial bar in which they are morticed, they face their work, then in any other position, when the machine is working at any other width, they will work sideways on, and so incur a liability to bend and break. Parallel expanding Horse-hoes were exhibited by the Earl of Ducie and other makers.—We did not see the Harrow which was exhibited last year at Derby, by Mr. Hopkin, of Ashbourne, Derbyshire. The following description is extracted from last year's Report:—"The Harrow is circular, like a cart-wheel, and lies flat on the ground, the tines passing through the felloes. A horizontal revolving motion is communicated to it, as it is drawn forwards, by means of an endless chain proceeding from a carriage in advance, and passing round a pully fixed upon, and concentric with, the rim of the Harrow, but of smaller diameter. The power is derived from the carriage-wheels, as in other cases. The execution of the apparatus was very imperfectly adapted to give effect to this novel idea, but the principle, perhaps, merits the attention of mechanics, as the double action, compounded of the progressive and circular movements, appeared to produce a very considerable comminution of the soil. Several circles of teeth may be inserted in the same wheel, and if it be found that the power used in giving the spinning or revolving motion be paid for in the quantity or quality of the effect, this construction might prove advantageous as a surface-pulveriser. The experi-

ment should be made with short small teeth." Improved as here suggested it would, we believe, prove an efficient implement.—A serrated chain or web Harrow, being an improvement upon that invented by Mr. Smith of Deanston, was exhibited by Messrs. Cottam and Hallen, of Winsley Street, London.

DRILL MACHINES.—We extract the following account of the origin and progress of drill machines from the Report of the Derby Show published in a late volume of the Society's Journal:—"The following concise history of the first introduction and progress of the manuring drill-system in Lincolnshire* has been obtained from sources on which it is believed full reliance may be placed; and its relation may have the effect of exciting the farmers of more backward districts to emulate those of a county excelled by none in Britain, in respect of the quantity of its produce, though far inferior to many in the natural fertility of its soil and character of its climate. The introduction of manure drills into Lincolnshire is comparatively of recent date. Previously to 1814, small single-row drills, attached to the plough for depositing Beans in every alternate furrow, and Turnip-seed drills, were the only seed-sowing machines used in the county. In 1814, the firm of Seaman and Hornsby, of Grantham, made a drill for depositing bones with Turnip-seed. In 1816, Mr. Gregory, of Nottingham, brought a sample of crushed bones to Grantham market, in a mahogany box, to exhibit to the farmers the perfection he had attained in reducing them to a small size. In the same year several spirited farmers purchased drills for bones. In 1817 these drills became general. In 1819 portable bone-mills were first introduced: these flourished but a short period, giving place to the large fixed steam-mills. In 1828 we first began to drill ashes mixed with bones. In 1839 originated the first attempt to improve the delivery of manure by means of stirrers in the drill-box; and by these improved machines the drilling of compost was effected. At present (1843) we presume to be able to deposit, by the drill, fold and stable-yard muck with our seed. For the rapid adaptation of the drill to this latter purpose we feel to be much indebted to the stimulus given to our mechanics by the Society. Neither Jethro Tull, the honoured father of the drill-system, nor the Rev. Mr. Cooke, the inventor of the Suffolk drill, dreamed of depositing manure of any kind with the seed; an addition which we consider to belong to the eastern counties' farmers, ambitious only at first to economise their then favourite manure, the bone. The Society's Prize of 30*l.* was awarded to Messrs. R. Garrett and Son, of Saxmundham, for their drill for general purposes. A mode of steerage was applied to this implement, which was thought to be calculated to render its use less difficult to novices, and to insure straightness in the lines. Facility in the guidance and management of these implements is a property of unquestionable importance, as providing for the more complete and safe action of the horse-hoe. It may not, however, be out of place to observe that experienced drill-men reject refined appliances of this kind as incumbrances. The late Earl of Leicester is said to have remarked that 'he would not employ a labourer who could not lead a drill-horse straight from Holkham to St. Paul's.'"—Messrs. Garrett, of Saxmundham, received the Society's Prize of 20*l.* this year also, for their Drill for general purposes. Since last year, they had added an arrangement by which the opening between the manure-box and manure-drill, upon which the quantity thrown out depends, may be easily regulated as the machine proceeds. This object has been attained in a manner much simpler, and practically, we apprehend, equally efficient, in a drill exhibited by Mr. Woodbourne. Mr. Hornsby, of Grantham, Lincolnshire, who received the Society's Prize of 10*l.* and a Silver Medal for the best Drill Presser, exhibited a variety of efficient implements under this class, among which was a two rowed Turnip Drill, which was probably the most efficient Manure Drill exhibited. The union of the traversing with the rotatory motion in the stirrers, for working pulverised manures, &c., down from the supply-box to the cups, which originated with this gentleman, was shown in several implements exhibited in the yard; but owing to its generally doing more than is wanted, and forcing the material out of the box faster than the cups can remove it, Mr. Hornsby has ceased to use it. If some simple means could be adopted for putting this apparatus easily and quickly out of gear at pleasure, as the machine proceeds, we think it would still be a useful attachment to the Manure Drill.—Mr. Newberry, of Chipping Norton, Oxon, exhibited his 4-wheel Dibbling Machine again. The efficiency of this implement has been amply demonstrated during the two seasons of Wheat-sowing in which it has been tried. A very favourable report by several practical farmers was given of this machine in a late volume of the Society's Journal. A field of Wheat near the trial ground had been sown by this machine, and was looking well.—Mr. Barnes's Drop Drill, manufactured at Nether Wallop, Hants, was constructed on a new principle. The intermittent nature of the delivery from this machine, both of the manure and seed, which constitutes its character as a drop drill, is obtained by means of an endless chain of tin cups, fastened at intervals of 9 inches on a revolving strap; these revolve in front of each coulter, each of the cups receiving a portion of the manure and seed supplied from their respective boxes, and descending, deposit their contents in succession on the ground as the machine proceeds; the motion of these straps being the same as that of the rim of the drill wheels, the seed is deposited at intervals of 9 inches in the rows, that being the distance of the cups from one another on the strap.—A Seed-Depositing or Planting Machine, exhibited by Mr. Henry Vingo, of Penzance, Cornwall, and another which had been previously exhibited at Bristol, acted on a principle peculiar to itself. The bottom of the seed-box was double, consisting of a fixed plate pierced at regular intervals, and a moveable one, also regularly fixed. The seed, it is evident, could only drop out of the box when these holes coincided; and by an arrangement, the motion of the under plate was regulated, so that this correspondence of the holes took place at regular intervals of time, producing an effect, in fact, somewhat similar to that of the drop drill. In one of these cases the motion of the under plate was a circular one, and in the other it had a reciprocating sliding motion.

THRESHING AND WINNOWING MACHINE.—Many threshing machines were exhibited by different makers, and a great variety of horse engines also, for connecting horse-power with them. In one of these a screw propeller was used for converting the horizontal rotatory motion of the horses into the vertical rotatory motion of the shaft connecting with the machine, *i. e.* the spur wheel on the vertical axle around which the horses walked was toothed obliquely into a worm on the aforesaid shaft. This simple arrangement was stated, though obviously erroneously, to lessen the power required to work the machine; the loss of power by it from friction must be very great.—A threshing machine on a new principle, invented by Messrs. Clyburn and Parsons, was exhibited by the Earl of Ducie. It consists of a revolving cone or beater, inclosed in an outer fixed concave case. The outer case is open work. The Corn is fed in at the smaller end of the concave case, and (by the difference in the velocity between the large and small end of the revolving cone or beater) the straw is carried rapidly to the larger end and discharged. The grain, as it is separated from the ear, is thrown through the trellis or open work, so that a complete separation takes place. The wind caused by the revolution of the beater is brought to operate upon the threshed grain, and blows out the greater portion of chaff; thus, at one operation, the threshing and first winnowing is performed.—Mr. Hornsby, of Grantham, exhibited a Winnowing Machine, to which was attached an admirable feed apparatus, capable of taking in and delivering regularly Grain and Chaff in the roughest condition. It consists simply of a peculiarly toothed roller, working in the bottom of a hopper. It is capable of chaffing Corn as it comes from the threshing machine, and dressing the same.—A Winnowing Maching, on an entirely original principle, demonstrating much ingenuity, was exhibited by the Earl of Ducie, Dursley, Gloucestershire, invented by Mr. Clyburn. The current of air was driven by means of an arrangement somewhat like the arm of a windmill, only that the radial arms of which it consisted were much more numerous, and twisted further round, so that, revolving as they did in a vertical plane, the air was caught by them at an angle, and propelled forward. A current of air, of a section equal to the surface of this arrangement of fans, was thus produced, and in the midst of this, a riddle, having a lateral oscillatory motion was placed; the Corn fell on this from a hopper above; the straw was separated and some of the Chaff blown off. All that passed the riddle was then collected in a very shallow hopper below the riddle, from the bottom of which it was again delivered up in a thin stream to the influence of the current of air. The double action of this current of air proved efficient as a Winnowing Machine.—A simple and apparently efficient Barley Hummeler, for which a Silver Medal was awarded, was exhibited by Mr. J. Cooch, of Harlston, near Northampton. To this implement was attached an endless chain of feeding buckets, for the purpose of lifting the grain from the floor, and throwing it into the machine—a useful attachment; for the efficiency of implements of this class depends much upon the regularity with which they are fed.

CAKE-CRUSHERS, TURNIP AND CHAFF-CUTTERS, &c.—The Society's Prize of 5*l.* was awarded to Mr. Hornsby, for the best Cake-crusher. Instead of having rollers with toothed surfaces, presenting the appearance, in fact, of a series of toothed wheels, strung, at short intervals, on a common axis, Mr. Hornby covers his rollers with a series of *pointed* teeth, or short pinnacles of case-hardened metal, the teeth on one roller corresponding in position to the intervals between those on the other.—A good Corn-crusher was exhibited by the Earl of Ducie, which differed from other machines in being grooved neither in a line with the axis nor spirally. It has a large and small roller, with a series of grooves turned in each in the form of a V, and fitting each other, the sharp edge of the V penetrating the grain; while the velocity of the grooves varying, produce a grinding motion.—Mr. Gardner, of Banbury, Oxon, exhibited his simple and efficient Turnip-cutter again, and was rewarded with a Prize of 5*l.* Many unsuccessful attempts have been made to produce an implement which shall excel this in all the points which constitute the excellence of an agricultural implement, viz. cheapness, simplicity, and efficiency. One of the best attempts is that by Mr. Phillips, of Bristol, in which the knives which cut the different sides of the pieces as they come from the machine are detached from one another. In one of the implements of this class exhibited by Mr. Phillips, a cross-cutting apparatus was attached, which shortened the finger-shaped pieces, in which the Turnip is delivered, into pieces an inch and a half long.—The Society's Prize of 10*l.* and Silver Medal was awarded to the Earl of Ducie, for his Lordship's Chaff-cutter. This implement differs from all others of this class in wanting that intermittance which characterises the cutting operation of all other chaff-cutters. The cutters consist of thin blades or knives with serrated edges, coiled spirally round a cylinder, thus insuring a continuous drawing cut, and requiring less power to cut a given quantity of material. From the peculiar arrangement of the cutters, the inconvenience and delay attendant upon removing them for the purposes of sharpening is avoided; this is done by turning the cylinder the back way round, and advancing an emery grinder towards the cutters. A simple method is also adopted for changing the length of cut, which is done by shifting the strap from one pair of pulleys to another; there are three pair; thus, when the strap is upon the large pulley on the axis of the cutting cylinder, and the small one on the shaft that drives the feed-rollers, it will cut three quarters of an inch long, and shorter by a quarter of an inch in every other pair of pulleys.—A Chaff-cutter exhibited by Messrs. Barrett and Exall of Reading, possessed a very simple mode of regulating the length of the cut at the will of the workman. The length of cut depends upon the relation between the rapidity with which the knives are made to revolve, and that of the rate at which the material to be cut is passed through the box. Now these two motions in all chaff-cutters are connected with one another by wheel and pinion, &c., and the object to be attained is some simple and easy means of varying this connection so that the one motion, that of the knives, being constant, the other, that of the material to be cut, may vary. This is effected in the instance before us by means of a disc on the axis of one of the feeding-rollers, on the face of which, in radial lines or nearly so, several series of tappets or teeth are arranged in circles about the centre of revolution. A shaft whose motion depends on that of the knives, revolves in front of this disc, and by means of a moveable pinion working into the aforesaid tappets, communicates its own motion to it. If this pinion work into one of the outer circles, the angular motion of the disc, and therefore that of the feeding-rollers, will be slow, and the chaff cut will be fine; if, on the contrary, it works into one of the inner circles, the chaff cut will be coarse. This important point, the length of the chaff, can also be regulated in another way. Suppose a toothed wheel be substituted in the stead of this disc, and in place of the pinion, a moveable worm be slipped on the aforesaid shaft; several worms for working thus into the wheel may be employed, according to the coarseness of chaff required, one taking one tooth, another two teeth of the wheel at a time, and so on. The motion of the shaft being constant, that of the disc will thus vary, and, as before, our object will have been attained. This mode of working chaff machines was exhibited by several makers in the yard. We single out one, Mr. Ward's, of Stratford-on-Avon, because of several other peculiarities in the machine he exhibited. One of them consisted in a beautiful arrangement by which the feeding-rollers were stopped while the cut of the machine was being made. It is evident that the efficiency of the worm, in communicating a motion to the disc, into which it works, and thereby to the feeding-rollers, depends on the obliquity of its thread to the axis of the shaft on which it is wound. In the case before us, the worm is of such a form, that its action in causing the disc to revolve ceases during a portion of its revolution. Two cuts being made during one of its revolutions, the thread of the worm in the course of one circle round the shaft on which it is wound is at two places oblique to the axis of the shaft, there producing motion in the feeding-rollers, and twice at right angles to it, there ceasing to produce motion; it is at the two portions of the revolution, when the feeding-rollers are thus at rest, that the cuts are made. Mr. Ward's Chaff-machine is named "Guillotine," from the nature of the cut which it makes; the arrangement for this purpose is as follows:—By means of a crank on the fly-wheel axle, a reciprocating vertical motion is given to a framework, which acts in slides in front of and across the feed-box. In this framework, a two-edged knife, inclined at an angle of about 30 deg., is placed in a vertical plane. This knife cuts off in its descent and ascent—its two edges coming into play alternately—the material protruded from the box between its motions. We have mentioned three modes of regulating the cut of chaff-machines.—A very simple arrangement, somewhat on the principle of the second kind, was shown in a machine exhibited by Mr. Gardener, of Banbury, Oxon. This implement had three knives, two of which were in action at once; and by means of a simple arrangement on this principle, the feeding-rollers stopped while each cut was being made.—A good Chaff-cutter, marked B, was exhibited by Messrs. Ransome, of Ipswich. It is made entirely of metal, and combines the best points of Messrs. Ransome's former machines, with some important improvements on them. These improvements consist in the facilities for changing the length of the cut by means of toothed wheels, and of further varying the lengths by shifting one knife without detaching it, thus doubling the length of each change. The rollers vary in distance, according to the feed; and, from their spiral form, they draw it at a uniform rate of motion. The presser-plate has a peculiar motion on the axis of the upper roller, so that whether the feed be thick or thin, a sufficient pressure is always applied; and thus the cut is made clean without drawing the short straws. Two horses will work it well, and may be estimated to cut 10 cwt. of straw per hour into half-inch lengths.

OTHER IMPLEMENTS.—Mr. Grant, of Stamford exhibited his excellent Horse Rake, which has gained prizes at many Agricultural Shows, and is now pretty

* "The Judges have set on foot inquiries relative to the origin of manure-drills in the south-eastern counties, but have not yet succeeded in establishing the historical dates to their satisfaction."

well known. As an implement of this kind we must mention the Corn Gatherer exhibited by the Messrs. Ransome; it consists of three large rakes, each attached to a common axle, and as each becomes filled, a simple act on the part of the driver releases it from its rigid position, and another takes its place. Implements hitherto made for the above purpose have been difficult to unload, even with the application of great strength to lift them over the gathered heaps. The gatherer leaves its load at the will of the driver without being lifted up, and without disturbing the heap it gathers together; while one of a treble row of tines alternately begin to gather the swathe, when the previous working tines have finished their heap, the size of which is regulated as required for one or two fork's full. The implement now exhibited is for one swathe at a time, the horse walking by the side of the swathe. For light Corn in large fields, the gatherer is made for two swathes at a time, and for very light land Corn may rake all the land (except where the row is left), clean at the same time. The principle upon which it acts is applied to horse-drag rakes, and by which much larger rows are got together than can be done by lifting up the rake, and thus save much time in getting up rakings.—The Society's prize of 30*l.* was awarded to Messrs. Ransome, for a neat and concise arrangement of three important implements, viz. Chaff-cutter, Bean-mill, and Mill for bruising other Grain; these are all driven by one and the same horse-power, and are situated within the circle described by the horse in its revolution.—Mr. Croskill exhibited his well-known Clod-crusher, which is superior to all other implements of the kind; it possesses the advantage, which the inventor has patented, of having every toothed wheel—of a series of which it in fact consists—slipped loosely on a circular axle. Each revolves in any case which requires it, independently of the others, and this not only diminishes the draught of the implement but makes it more efficient and easily turned at the land ends.—Many Waggons, Carts, Harvest-carts, &c., were exhibited by Mr. Stratton of Bristol, and Mr. Croskill of Beverley.—The Society's Prize of 15*l.* and Silver Medal for the best Waggon was awarded to Mr. Coombes of Shipton, near Burford, Oxon. It consisted of two parts, either of which might be taken apart and used as a cart; as both ends of the Waggon were alike, and shafts could be slipped in at either end.—An excellent Churn, to which a prize of 10*l.* was awarded, was exhibited by Mr. Harkes of Mere, near Knutsford, Cheshire. This, which is an upright cylinder, contains within it two frameworks of beaters revolving on the same upright shaft, one within the other, but by means of a very simple arrangement of bevil wheels, above the implement, they are made to move in contrary directions, thus producing a most perfect commixture and agitation of any fluid in the barrel.—A great variety of Weighing Machines were exhibited by Messrs. James of Fish-street Hill, and Messrs. Cottam and Hallen of Winsley-street, London.—A variety of Draining-tile Machines, of various sizes and prices were exhibited by Mr. Etheridge, of 11, Furnival's Inn, London.—A Draining-tile machine on Etheridge's principle, possessing two cylinders for holding clay, so that one could be filling while the other was at work, was exhibited by Messrs. Barrett and Exall, of Reading.—A simple Level, to be used in draining operations, was exhibited by Mr. Bailey Denton, of Southampton; who also exhibited his Model Map in relief, of an estate, shown at Derby last year. The principle of this Level lies in the fact that the vertical line from the angle of an upright isosceles triangle, the extremities of whose sides rest on a horizontal plane, will bisect the angle contained by those sides, and any lowering of one leg will be attended by a corresponding displacement of the vertical line. The implement is thus in form a pair of compasses, the legs of which are fixed at a distance from each other of 5 feet, by means of a cross-bar. From the apex is suspended a plumb, and in one leg there is fixed a sliding-sight and vernier, while on the other there are cross-hairs. To use this instrument a person has only to send forward, to the spot where it is intended to bring out the drain, a stick with a paper fixed in it the exact height of the line of sight in the instrument from the ground level; he then, with the instrument adjusted by the plumb to a true level, raises or depresses the sliding-sight in one leg until the cross-hairs in the other cut the paper in the stick. From the vernier he will read the rise or fall (per 5 feet) which will enable him to set the shifting limb to a corresponding division in the index on the bar, to which the workmen will afterwards work the plumb line.—An excellent self-recording Dynamometer, was exhibited by the Earl of Ducie, invented and manufactured by Mr. Clyburn, Dursley, Gloucestershire. This instrument records on a roll of paper the distance which the plough or other implement may have passed over, and the weight necessary to draw it through all its variations. It consists of a right and left-hand spiral spring, placed one within the other, to economise room. When the power is applied, the springs are compressed, which gives motion to a rack and pinion that has a pulley fixed on the same spindle; this pulley has a chain passing round it which gives motion to a pencil and pointer, the pencil acting upon a roll of paper, each division in the length of which is twenty-five yards of ground passed over, and each division in the width is 112 pounds of force applied to the instrument; this paper has motion given to it from a pair of wheels which roll upon the ground, while the pencil is moved backward and forward according to the power applied, thus drawing a line on the paper, shewing the draught and the distance passed over. It is impossible to suppose but that in the foregoing report of the Implement Show of Southampton, drawn up from a necessarily hurried examination, many valuable implements have been overlooked. Should this have been the case with anything possessing good claim to be classed as a *new* implement, we shall be happy to correct our error, on being supplied with the means of doing so.

Trial of Implements.—Towards noon on Tuesday those who had congregated in such numbers at the Implement yard, began to move off towards Swathling farm, on the Winchester-road, where ground had been secured for the trial of implements. This was not so much for the information of the Judges, who had already determined on the merits of the implements from a private trial of them on the previous day, as for that of purchasers and others anxious to judge for themselves in the matter. On reaching the ground, we found it extremely hard from the effects of the weather—unfit indeed to show the action of most implements. Various drilling-machines, cultivators, harrows, rollers, horse-hoes, &c., were tried in an adjoining field after the ploughing was over; some of them performed their work excellently well. Crosskill's clod-crusher—the land was just in condition for it—proved a most efficient implement. We shall not, however, describe this part of the trial, the more, because owing to the great confusion which prevailed, very little information could be gathered from an inspection of the work. In the other field 16 ploughs had started work; they were arranged as follows:—

No.	Character of Implement.	Name of Exhibitors.
1	Two-wheel Iron Plough	Mr. Hill, Brierly, Dudley.
2	One-wheel Plough	Messrs. Tasker and Fowle, Andover.
3	Swing Plough	Mr. Clyburn, Uley, Gloucestershire.
4	American Plough* (Swing)	Messrs. Hughes, Norse, and Mason.
5	Eagle Swing Plough	
6	Two-wheel Plough, W.S.	Messrs. Saunders & Williams, Bedford.
7	One-wheel Plough	Mr. Clark, Romsey.
8	Wheel Plough, J. H.	Mr. Howard, Bedford.
9	Ditto, Ransome's, Y.D.	Messrs. Sims and Brown, Tollard Royal, Dorsetshire.
10	Ditto Ditto	Mr. Howard, Bedford.
11	Smart's Turn-rest Plough	Mr. Simmons, Sittingbourne.
12	One wheel Plough	Messrs. Barrett and Exall, Reading.
13	Lowcock's Patent Turn-rest	Messrs. Ransome, Ipswich.
14	Wheel Plough, Y.M.	Ditto
15	Ditto, Y.O.	Ditto
16	Ditto, Y.L.	Ditto

When the skilfulness of ploughmen varies much, the performance of ploughs is not a perfectly accurate test of their efficiency; and in this case the land was extremely hard; the exhibition could not, therefore, be taken as fairly testing the implements tried. We find, however, from notes taken before ascertaining, except in one instance, the names of the implements, that their work was classifiable as follows in point of excellence; the figures refer to the above list:—

I. Nos. 6 and 10.
II. Nos. 7, 12, 13, and 16.
III. Nos. 1, 2, 8, 9, 11, 14, and 15.
IV. No. 3.
V. Nos. 4 and 5.

The wheel ploughs exhibited greatly superior work to the swing plough. There was much less difference between I. and II., and II. and III. than there was between III. and IV., and IV. and V. The performance of No. 3 was very poor compared with the others, and that of 4 and 5 was wretchedly bad. We must not forget to mention that close by the trial ground a field had been laid out in plots, each of which exhibited the effects of some particular manure on Rye-grass. The weather had been greatly against the trial, so that very little difference was apparent amongst them. That on which nitrate of potash had been applied appeared to be of the darkest colour; that on which oil-cake had been spread appeared to be rather the best of the number; while the plot to which farm-yard manure had been applied, differed from all the others in the number of weeds, chiefly Thistles, with which it was covered; thus singularly verifying the accuracy of Mr. Bernay's remarks in a late *Gazette*, on the inability of fermentation in manure to destroy the vitality of seeds contained in it.

On Wednesday, at 5 p.m., the Council dinner took place at the Victoria Archery Room. Nearly 400 gentlemen sat down. Lord Spencer, the President of the Society, was in the chair, and many noblemen among its chief supporters were on the platform.

After the usual loyal toasts, which were most heartily received, Lord Spencer stated that the Duke of Cambridge had been over the implement and cattle yard that morning, though unable to be at the dinner, and with reference to the latter place, he had to apologise for having broken one of the rules of the Society, his Royal Highness having gone through the yard while the Judges were still at work inspecting the animals, this being in direct contravention of a positive rule. This explanation was received with loud cheers. The next toast, "The Professors of Science," was proposed by Lord Ashburton, who, in the course of his remarks on the connexion between science and farming, or rather on the union of intellect and manual labour in the production of some of the most useful machines, stated that two, the earliest in use, and those on which most labour and thought had been expended—the ship, and the plough—were precisely those about the proper form of which we still remain in most doubt. In returning thanks for the hearty manner in which this toast was received, Dr. Buckland entered into considerable detail as to the capability of the Hampshire District of improvement. He said that many thousand acres of it were lying in a worthless condition—equally so with that of the barren mountain heaths of central and northern England—but that the insuperable difficulty in the way of the improvement of these, viz., want of a good climate, did not exist in the way of Hampshire improvers. The course of improvement to be followed by them, consists in carrying clay to the sandy soils, and chalk after drainage upon clayey soils; both of these materials are within the reach of the Hampshire farmer. The expense is from 5*l.* to 10*l.* per acre, but the improvement is certain and permanent—it will last for ever—no mismanagement on the part of the tenant can destroy it. Instances of this are frequent. Portions of Bagshot Heath and Ascot Heath have thus been converted into fertile land, and a case was mentioned of land in Ireland formerly worth 5*s.* an acre, now yielding, in consequence of this treatment, large crops of good Hay. Dr. Buckland then referred to guano, a natural manure existing in beds of such enormous thickness in many tropical islands, that to speak of it, fairly came within his province as a geologist. He spoke of the apparent failure of that and most other concentrated manures this year, in consequence of the dry weather, and advised agriculturists to let all their this year experiments go for nothing, and not be deterred from trying guano largely next year, when it would certainly be much cheaper, as upwards of 60,000 tons of shipping were already at sea in that trade.—The award of premiums for cattle, &c., was then read by Lord Spencer. We give it below entire, although the award for horses was not read on that occasion, as, stallions being removed from the yard every night, would of course not be brought back again for exhibition on the Thursday, if it became known to whom the prizes had been awarded.

AWARD OF PREMIUMS.

Prizes for Improving the Breed of Cattle, 1844.

Short-Horns.

Class 1.—To the owner of the best Bull calved previously to the 1st of January, 1842, *Thirty Sovs.*, awarded to Mr. John Cooper, of Bonkwood, Thurgarton, Southwell, Notts, for his Short-horned Bull, 3 years, 1 month, and 13 days old, bred by himself.

To the owner of the 2d best ditto ditto, *Fifteen Sovs.*, awarded to Mr. Hayter, M.P., of Wells, Somerset, for his Short-horned Bull, 2 years and 10 months old, bred by Mr. Unsworth, of Blackrod, Lancaster.

2. To the owner of the best Bull, calved since the 1st of Jan., 1842, and more than one year old, *Twenty Sovs.*, awarded to Mr. W. Foulds, of Kirklington, near Southwell, Notts, for his Short-horned Bull, 2 years, 3 months, and 22 days old, bred by Mr. Milward, of Hexgrove Park, Southwell.

3. To the owner of the best Cow in milk, *Fifteen Sovs.*, awarded to Mr. John Booth, of Killerby, Catterick, Yorkshire, for his Short-horned Cow, 3 years, 2 months, and 5 days old, bred by himself.

4. To the owner of the best in calf Heifer, not exceeding 3 years old, *Fifteen Sovs.*, awarded to his Grace the Duke of Devonshire, of Chatsworth, Bakewell, Derbyshire, for his Short horned Heifer, 2 years and 5 months old, bred by Mr. Watson, of Walkeringham, Bawtry, Yorkshire.

5. To the owner of the best Yearling Heifer, *Ten Sovs.*, awarded to Mr R. Booth, of Warlaby, Northallerton, Yorkshire, for his Short-horned yearling Heifer, 1 year, 2 months, and 3 weeks old, bred by himself.

Herefords.

Class 1.—To the owner of the best Bull calved previously to the 1st of January, 1842, *Thirty Sovs.*, awarded to Mr. W. Perry, of Monkland, Leominster, for his Hereford Bull, 2 years, 7 months, and 28 days old, bred by himself.

To the owner of the 2d best ditto ditto, *Fifteen Sovs.*, awarded to Mr. G. Brown, of Avebury, Wilts, for his Hereford Bull, 2 years and 7 months old, bred by himself.

2. To the owner of the best Bull, calved since the 1st of Jan., 1842, and more than one year old, *Twenty Sovs.*, awarded to Mr. J. N. Carpenter, of Eardisland, near Leominster, Hereford, for his Hereford Bull, 1 year, 8 months, 3 weeks, and 4 days old, bred by himself.

3. To the owner of the best Cow in milk, *Fifteen Sovs.*, awarded to Mr. G. Drake, of the Manor Farm, East Tytherley, Stockbridge, Hants, for his pure Hereford Cow, 8 years and 10 months old, bred by Mr. Price, of Pool House, Upton on Severn.

4. To the owner of the best in-calf Heifer, not exceeding three years old, *Fifteen Sovs.*, awarded to Mr. J. N. Carpenter, of Eardisland, near Leominster, Herefordshire, for his Hereford In-calf Heifer, 2 years, 8 months, and 18 days old, bred by himself.

5. To the owner of the best Yearling Heifer, *Ten Sovs.*, awarded to Mr. J. Walker, of Burton, near Worcester, for his Hereford Yearling Heifer, 1 year and 8 months old, bred by Mr. C. Walker, of Sutton.

Devons.

Class 1. To the owner of the best Bull, calved previously to the 1st of January, 1842, *Thirty Sovs.*, awarded to Mr. Geo. Turner, of Barton, near Exeter, for his Devon Bull, 2 years and 8 months old, bred by himself.

To the owner of the second best ditto ditto, *Fifteen Sovs.*, awarded to Mr. Thomas Norcombe, of Hopcott Farm, Minchead, Somerset, for his pure Devon Bull, 4 years and 9 months old, bred by himself.

2. To the owner of the best Bull calved since the 1st of Jan., 1842, and more than one year old, *Twenty Sovs.*, awarded to Mr. T. Reynolds, of Raddon Court, Thoverton, Exeter, for his pure North Devon Bull, 2 years and 5 months old, bred by Mr. A. Parsons, of Litton, Devon.

3. To the owner of the best cow in milk, *Fifteen Sovs.*, awarded to Mr. G. Turner, of Barton, Exeter, for his Devon Cow, 6 years and two months old.

4. To the owner of the best in-calf Heifer, not exceeding three years old, *Fifteen Sovs.*, awarded to Mr. G. Turner, of Barton, near Exeter, for his Devon in calf Heifer, 2 years and 2 months old.

5. To the owner of the best Yearling Heifer, *Ten Sovs.*, awarded to Mr. James Hole, of Knowle, near Dunster, Somerset, for his Devon Yearling Heifer, 1 year, 7 months, and 2 days old, bred by himself.

Cattle of the Channel Islands Breed.

Class 1. To the owner of the best Bull calved previously to the 1st of Jan., 1843, *Fifteen Sovs.*, awarded to Mr. W. J. G. Phillips, of Eling Vicarage, Southampton, for his Channel Island Bull, 2 years and 4 months old, bred by himself.

2. To the owner of the best Bull calved since the 1st of Jan., 1843, and more than one year old, *Ten Sovs.*, awarded to Mr. W. B. Cater, of West End, Southampton, for his Channel Island Bull, 2 years and 5 weeks old, bred by Mr. W. Gibbs, of Rebenor, Essex.

3. To the owner of the best Cow in milk, *Ten Sovs.*, awarded to Mr. C. W. Robin, of Petit Minage, St. Heller, Jersey, for his pure Jersey Cow, 2 years and 6 months old, bred by Mr. J. Hocquard, of Granville, Jersey.

4. To the owner of the best in-calf Heifer, not exceeding two years old, *Ten Sovs.*, no competition.

1. To the owner of the best Yearling Heifer, *Seven Sovs.*, awarded to Mr. John Blake, of Bean Regard, St. Heliers, Jersey, for his pure Jersey yearling Heifer, 1 year, 1 month, and 16 days old, bred by Major Bridgeham, of St. Laurens, Jersey.

CATTLE OF ANY BREED, OR CROSS;

Not qualified to compete in the foregoing classes.

Class 1.—To the owner of the best Bull calved previously to the 1st of January, 1842, *Thirty Sovs.*, awarded to Mr. W. Brine, of Tolpuddle, near Dorchester, for his pure long-horned Bull, 4 years and 5 months old, bred by the late Mr. Thomas Wyatt, of Hanwell Park, near Banbury.

To the owner of the second best ditto, *Fifteen Sovs.*, awarded to Mr. Thomas Jenner, of Cowdray Park Farm, Petworth, Sussex, for his pure Sussex Bull, 3 years and 4 months old, bred by himself.

2. To the owner of the best Bull calved since the 1st of Jan., 1842, and more than one year old, *Twenty Sovs.*, awarded to Mr. Thomas Dowden, of Mitcheldever, Andover Road, Hants, for his Hereford and Durham Bull, 2 years and 2 months old, bred by himself.

3. To the owner of the best Cow in milk, *Fifteen Sovs*, awarded to the Hon. M. W. B. Nugent, of Higham Grange, Hinckley, Leicestershire, for his pure Leicester or long-horned Cow, 10 years and 2 months old, bred by Mr. Ball, of Snowford Lodge, Long Ichington, Southam, Warwickshire.

4. To the owner of the best in-calf Heifer, not exceeding three years old, *Fifteen Sovs*, awarded to the Hon. M. W. B. Nugent, of Higham Grange, Hinckley, Leicestershire, for his pure Leicester or long horned in-calf Heifer, 3 years and 11 days old, bred by himself.

5. To the owner of the best Yearling Heifer, *Ten Sovs.*, awarded to Mr. W. J. Calhoun, of Binderton, near Cheshire, for his short-horned and Hereford yearling Heifer, 1 year and 2 months old.

HORSES.

Class 1.—To the owner of the best Stallion for Agricultural Purposes, of four years old and upwards, *Thirty Sovs.*, awarded to Mr. Thomas Catlin, of Butley, Woodbridge, Suffolk, for his Cart Stallion, 4 years old, bred by himself.

To the owner of the second best ditto ditto, *Twenty Sovs*, awarded to the Right Hon. the Earl of St. Germans, St. Germans, Cornwall, for his aged Cart Stallion.

2. To the owner of the best two years old ditto, foaled since the 1st of Jan., 1842, *Fifteen Sovs*, awarded to the Right Hon. Lord St. John, of Melchbourne, Kimbolton, for his Cart Stallion, 2 years and 2 weeks old, bred by his lordship.

3. To the owner of the best Mare and Foal for agricultural purposes, *Twenty Sovs.*, awarded to Mr. W. Fowle, of Market Lavington, Devizes, Wilts, for his Cart Mare and Foal; sire of foal belonged to Mr. H. Iggs, Penzelwood, Somerset.

To the owner of the second best ditto, *Ten Sovs.*, awarded to Mr. G. W. Roberts, of King's Walden, Hitchen, Herts, for his Cart Mare and Foal; mare bred by himself: sire of foal belonged to Mr. Linden, of Arrington, Cambridge.

4. To the owner of the best two-years-old Filly for agricultural purposes, *Ten Sovs.*, awarded to Mr. W. Fowle, of Market Lavington, Devizes, for his 2-year-old filly, bred by Mr. H. Delaney, of Hemmingford Abbotts, near St. Ives, Hants.

5. To the owner of the best Thorough-bred Stallion, which shall have served mares at a price not exceeding three guineas, (and with a groom's fee of not more than five shillings,) in the season of 1844, *Thirty Sovs.*, awarded to Mr. Curtis, of Ellingstoke, for his thorough-bred stallion, 4 years old, foaled by Langar, dam by Cervantes, out of Marsana, by Selim.

SHEEP.

Prizes for Improving the Breed in Sheep: 1844.

LEICESTERS.

Class 1. To the owner of the best Shearling Ram, *Thirty Sovs*, awarded to Mr. J. G. Watkins, of Woodfield Ombersley, Stourport, Worcestershire, for his pure Leicester Ram, 17 months old, bred by himself.

To the owner of the second best ditto, *Fifteen Sovs.*, awarded to Mr. T. E. Pawlett, of Beeston, Biggleswade, Beds, for his Leicester Ram, 15 months old, bred by himself.

2. To the owner of the best Ram of any other age, *Thirty Sovs*, awarded to Mr. T. E. Pawlett, of Beeston, Biggleswade, Beds, for his Leicester Ram, 28 months old, bred by himself.

To the owner of the second best ditto, *Fifteen Sovs.*, awarded to Mr. T. E. Pawlett, of Beeston, Biggleswade, Beds, for his Leicester Ram, 40 months old, bred by himself.

3. To the owner of the best pen of five Shearling Ewes, *Ten Sovs.*, awarded to Mr. J. G. Watkins, of Woodfield, Ombersley, Stourport, for his pen of five pure Leicester Shearling Ewes, bred by himself

To the owner of the second best ditto ditto, *Five Sovs.*, awarded to Mr. John Beasley, of Chapel Brampton, Northampton, for his pen of five improved Leicester Shearling Ewes, 16 months old, bred by himself.

SOUTHDOWN SHEEP.

Class 1. To the owner of the best Shearling Ram, *Thirty Sovs*, awarded to Mr. Jonas Webb, of Babraham, Cambridge, for his Southdown Ram, 16 months old, bred by himself.

To the owner of the second best ditto, *Fifteen Sovs.*, awarded to his Grace the Duke of Richmond, of Goodwood, Chichester, Sussex, for his Southdown Ram, 16 months old, bred by his Grace.

2. To the owner of the best Ram of any other age, *Thirty Sovs.*, awarded to Mr. J. Beaven, Jun., of Gore Farm, Market Lavington, for his Southdown Ram, 52 months old, bred by himself.

To the owner of the second best ditto, *Fifteen Sovs.*, awarded to Mr. T. Ellman, of Beddingham, Lewes, Sussex, for his Southdown Ram, 27 months old, bred by himself.

3. To the owner of the best pen of Five Shearling Ewes, *Ten Sovs.*, awarded to His Grace the Duke of Richmond, of Goodwood, Chichester, for his pen of five Southdown Shearling Ewes, 16 months old, bred by his Grace.

To the owner of the second best ditto ditto, *Five Sovs.*, awarded to Mr. D. Barclay, M.P., of Eastwick Park, Leatherhead, Surrey, for his pen of five Southdown Shearling Ewes, 17 months old, bred by himself.

LONG-WOOLLED SHEEP:

Not qualified to compete as Leicesters.

Class 1.—To the owner of the best Shearling Ram, *Thirty Sovs.*, awarded to Mr. C. Large, of Broadwell, Burford, Oxon, for his new Oxfordshire Ram, 16 months old, bred by himself.

To the owner of the second best ditto, *Fifteen Sovs.*, awarded to Mr. C. Large, of Broadwell, Burford, Oxon, for his new Oxfordshire Ram, 16 months old, bred by himself.

2. To the owner of the best Ram of any other age, *Thirty Sovs.*, awarded to Mr. E. Handy, of Sevenhampton, Andoversford, Gloucestershire, for his improved Cotswold Ram, 40 months old, bred by himself.

To the owner of the second best ditto, *Fifteen Sovs.*, awarded to Mr. E. Handy, of Sevenhampton, Andoversford, Gloucestershire, for his improved Cotswold Ram, 40 months old, bred by himself.

3. To the owner of the best pen of five Shearling Ewes, *Ten Sovs.*, awarded to Mr. E. Smith, of Charlbury, Oxon, for his pen of new Oxfordshire Long-woolled Ewes, 18 months old, bred by himself.

To the owner of the second best ditto ditto, *Five Sovs.*, awarded to Mr. James Linton, of Hemmingford Abbotts, St. Ives, Hants, for his pen of five Lincoln and Leicester Ewes, 16 months old, bred by himself.

SHORT-WOOLLED SHEEP:

Not qualified to compete as South Downs.

Class 1.—To the owner of the best Shearling Ram, *Twenty Sovs.* Prize withheld for want of merit.

2. To the owner of the best Ram of any other age, *Twenty Sovs*, awarded to Mr. Thomas Hutton, of Upton Gray, Odiham, Hants, for his Hampshire Down Ram, 29 months old, bred by himself.

3. To the owner of the best pen of Five Shearling Ewes, *Ten Sovs.*, awarded to Mr. W. Humphrey, of Chaddleworth, Newbury, Berks, for his pen of five Berkshire Short-woolled Ewes, 18 months old, bred by himself.

PIGS.

Class 1.—To the owner of the best Boar of a large breed, *Ten Sovs.*, awarded to Lieut.-Colonel Thornhill, of New Park, Lyndhurst, Hants, for his Boar, 36 weeks old, bred by Mr. W. P. Thornhill, of Stanton, Bakewell, Derbyshire.

To the owner of the 2d best ditto ditto, *Five Sovs*, awarded to Mr. Pusey, M.P., of Pusey, Faringdon, Berks, for his Berkshire Boar, 2 years and 1 month old, bred by Mr. J. Harris, of Hinton.

2. To the owner of the best Boar of a small breed, *Ten Sovs.*, awarded to Mr. W. F. Hobbs, of Marks-hall, Kelvedon, Essex, for his improved Essex Boar, 10 months old, bred by himself.

To the owner of the 2d best ditto ditto, *Five Sovs.*, awarded to the Rev. W. Hocken, of St. Endallion, near Camelford, Cornwall, for his improved Essex Boar, 27 weeks and 3 days old, bred by himself.

3. To the owner of the best breeding Sow of a large breed, *Ten Sovs.*, awarded to Mr. P. Pusey, M.P., of Pusey, Faringdon, Berks, for his Berkshire Sow, 1 year and 6 months old, bred by Mr. J. Blandy, of Kingston, Berks.

4. To the owner of the best breeding Sow of a small breed, *Ten Sovs.*, awarded to Mr. A. P. Falconer, of Beacon Hordle, Christchurch, Hants, for his Yorkshire Sow, 11 months and 3 weeks old, bred by Mr. J. W. Nutt, York.

5. To the owner of the best pen of three breeding Sow-Pigs, of the same litter, above four and under nine months old, *Ten Sovs.*, awarded to Mr. Joseph House, of Beatwall, near Wareham, Dorset, for his pen of three Dorsetshire Sow-Pigs, 34 weeks old, bred by himself.

Shortly after reading the above award, the company separated.

A Public Meeting for the purpose of establishing an Agricultural College was held this day at the Freemasons' Hall, at 2 o'clock. The attendance was not numerous, as most of the agricultural visitors were engaged at the implement-yard. What, however, the meeting lacked in point of numbers was made up by the great respectability of the parties present, among whom were the Duke of Richmond, Lord Ducie, Mr. Pusey, M.P.; Mr. Escott, M.P., Oxford; Mr. Goddard, Drs. Buckland, Daubeny, and Playfair.—The chair was taken by Mr. Pusey, who stated the object of the meeting, and pointed out the advantage that would accrue to the agriculturist from the establishing such a College. The project had been taken up by many of the leading agriculturists, not only in the immediate district in which it was intended to establish the College, but in other counties. Lord Bathurst had, in addition to providing a suitable farm of 400 acres, on which the College and other buildings were to be erected, advanced 2000*l.* in furtherance of the object.—The Duke of Richmond, in proposing the first resolution, said that he had declined to take shares in the proposed Society, upon the principle that every shareholder should have time to attend to the details of the Society to which he had put his name, so that by so doing he might not mislead others to add their names, upon the faith of seeing his name, and thereby supposing that he would attend to its practical operations. He would avoid that evil, as he was aware that his many other avocations would prevent him from giving sufficient attention to the details. He, however, so highly approved of the Society, that although he could not become a subscriber for the reason he had stated, yet he most gladly gave a donation to promote its establishment. He would not have the Committee be too sanguine of making any profit from the farm. He was a farmer himself, and he was aware that farming was not so profitable as most other pursuits. He was of opinion that Schools of Agriculture were much wanted in the country, and he had great pleasure in proposing the first resolution (which was seconded by Dr. Playfair):—"That Schools of Agriculture are much wanted in this country, in which a knowledge of the sciences now admitted to be essential to the successful pursuit of Agriculture may be learned, in connection with the practical working of a farm on the most approved principles."—Mr. Escott proposed the second resolution, and said that he gladly availed himself of joining a meeting that had so important an object in view. He, in common with many other persons, had long deplored the want of a proper establishment for the education of the agricultural population in pursuits adapted to their after life. A most important fact was developed and published by the agriculturists themselves, as the wish to establish a College originated from a Farmers' Club. The object of the meeting had his most cordial support, and he moved the following resolution (which was seconded by Mr. N. Goddard):—"That the plan for the establishment of an Agricultural College near Cirencester, explained by the deputies attending this meeting, is calculated to effect that desirable object."—The next resolution was to have been proposed by Lord Spencer, but the Duke of Richmond explained to the meeting that that nobleman was unavoidably absent in consequence of being in attendance on his Royal Highness the Duke of Cambridge, who was inspecting the Show-yard. In the absence of Lord Spencer, Dr. Buckland proposed, and Mr. Eyle seconded the resolution, "That this meeting warmly recommends the agricultural community to give every support and encouragement to the establishment of the College, which they regard as the first step in the right direction for training up the rising generation of farmers upon a sound foundation; and they would especially urge on farmers generally the importance of securing to their children, intended for the same occupation, the great advantages to be derived from the kind of education provided by such an institution."—The Duke of Richmond proposed, and Dr. Daubeny seconded a vote of thanks to Mr. Pusey for the service he had rendered to the agriculturists generally, and for his conduct in the chair.—Mr. Pusey briefly replied, and congratulated the meeting upon the object they had in contemplation being fully carried out, when they saw the noblemen present, and the member for the University of Oxford, as well as two of the distinguished professors, come forward to take them by the hand.

On Thursday the Cattle Yards were opened at six o'clock in the morning, and very soon began to fill. Towards noon there must have been many thousands within them. It is unnecessary to say much respecting the character of this Exhibition. There was an excellent show of Hereford and Devon cattle, which mustered in much greater numbers than the Short-horns. The show of South Downs among the sheep was also much the finest part of the Exhibition under this head. There was a good show of pigs; some of the Essex breed, exhibited by Mr. F. Hobbs, of Kelvedon, were extraordinarily fat. It is impossible to speak too highly of the general arrangements of the Show Yard, for which the Society is indebted to Mr. B. Gibbs. Notwithstanding the immense number of people within the Yard, and the immense number of cattle and sheep, &c., requiring food and attendance, everything proceeded without the least jar or confusion. Admirably arranged catalogues were to be had, containing a reference to everything in the Yard, so that a visitor could easily and without waste of time find what he wished to examine.

The Dinner of the Members of the Society took place in the evening, in the Pavilion erected for the purpose. The chair was taken by Lord Spencer at 4 P.M.; from 1200 to 1400 gentlemen must have been present. We are unavoidably compelled to give our readers, in this No. of the *Gazette*, but a meagre report of the proceedings at this interesting meeting. We select for report, the speeches connected with one of the many toasts of the evening—the toast of the Society, "Practice with Science," which was proposed by Lord Portman, and responded to by Dr. Playfair, in the absence of Prof. Daubeny. His lordship, in the course of his speech, illustrated the importance to agriculture, of well-conducted experiments, and the difficulty, though accurately performed, of deducing correct inferences from them. Of what use would it be to farmers then present, were he to detail to them experiments he had performed, connected with most important branches of agriculture, if he withheld information upon which, no less than upon the special forces he might have put in action, their results had depended?—he alluded to information on his soil, climate, his accessibility to manure, his supply of labour, &c. In responding to this toast, Dr. Playfair observed, that it was a sign of the present time, that in agriculture, as had been the case in medicine, people were beginning to trace out causes, and not merely look at their effects. Let us hope that in agriculture, as has been the case in medicine, the most beneficial results may flow from this system. He stated that the efforts of scientific men in this cause, had been productive of good within the still short period of the Society's existence. One instance of this was the success of their endeavour to bring guano into notice as a fertilising manure. At the time of the Liverpool Meeting, a single ship-load had been imported, with much anxiety as to the result, on the part of those interested in the speculation. Now, 60,000 tons of shipping were abroad to supply the demand for this article alone. Dr. Playfair then gave a curious instance of the manner in which the *dicta* of scientific men, being wrongly apprehended by the unlearned, become injurious instead of beneficial. An article was sold some time ago under the name of Dr. Daubeny's sulphate of ammonia, which, on examination, was found to be wholly innocent of any trace of ammoniacal salts. The Professor had recommended the mixture of gypsum with gas-water, the natural effect of which is to produce a solution of sulphate of ammonia, and cause a deposit of carbonate of lime. The ignorant manufacturer had retained the chalk, selling it as sulphate of ammonia, and thrown away the water containing all the ammoniacal salt that was present. It was as if the dairyman, in the manufacture of cheese, had kept the whey and thrown away the curd. Dr. Playfair then remarked on the enormous adulteration of which many manures were susceptible, without betraying it externally; and he stated that the cause of many of the contradictory results obtained from the use of manure might be traced to this fact—that manures of different kinds and intensities were thus frequently sold under a common name, while in point of fact they were as different from one another as possible. We shall probably report at additional length the proceedings of this meeting in our next.

Towards evening on this day the weather, which had been warm and clear throughout the week, changed. Rain, however, did not fall till fine weather, so far as the exhibitions and proceedings of the Society were concerned, was no longer in the least required.

FARMERS' CLUBS.

Bromsgrove.—At the annual meeting of this Club, Mr. Smith, of Deanston, delivered an instructive practical lecture on Thorough-Draining. Mr. Smith observed that water on land had two origins—that which was caused by springs from the earth beneath, and that which fell from the clouds in the shape of rain: and he had found from experience that it was better that this water should be drained away a certain depth beneath

the surface, that it should be drained off by running over the uppermost or active soil. In clay districts, where the clay was found to be stiff and impervious to water, and was thrown into ridges of, say 6 feet, the active soil being thin, the water running over the surface damaged that part of the land near to the furrows, little was grown, and the plant was found to be stiff and spiry. When the drain was first cut in a stiff clay soil, there being no opening or crack in the land, the water at first was found to lie upon it, but soon afterwards the clay began to contract, it consequently occupied less space, and fissures were quickly perceptible in the body of the clay. At first these cracks were small, but it would be found from observation that they continued to extend all over the body of the soil betwixt the two drains; in a short time the whole of the land was found to be full of fissures, and in a completely spongy state. If the water remained in these fissures, the land would soon become as impervious as ever, but the cracks, which were found to be vertical as well as horizontal, suffered the water to pass along, and eventually it found its way into the opening of the drain by the fall which had been given, and the water ran from the field altogether, the active soil by this means being left completely dry. Practical experience had shown to him that the most advantageous depth for a drain was from 2 to 3 feet. He had also remarked that when the water fell into the soil, it expelled the air; that had been found to have a most beneficial effect on the soil, and the moment the water fell down, another portion of atmospheric air found its way into its place; thus the alternate action of water and the atmosphere materially benefited the land, because by this means a much greater depth of soil was obtained than if the land had remained in its stiff and impervious state. One great advantage of a 30-inch drain over one of 18 was, that if they went to plough immediately after rain had fallen, they avoided that puddling which was certain to be caused by the weight of a horse or cart where the shallow drain had been used. Another advantage in having the water sink into the surface was this: rain generally brought large quantities of ammonia; this was left in the soil by the under-draining, and must certainly be better than if the water ran merely along the surface. In cases, too, where large quantities of rain fell, it was important that every part of the land should bear equally the burthen of it; this could not be if it was suffered to run on to particular spots. Every one knew that the great object of farming was to produce the largest possible amount of grain, or crop of any kind, from any given area of surface; but that could not be accomplished unless every bit of the land produced an equal quantity with the rest. But there were other advantages of under-draining. By it the water did not pass too quickly into the drain; and if it was allowed to pass through the land slowly, in fact, almost by filtration, it had time to deposit everything it held in suspension in the soil, which was a great advantage. In all drains, properly executed, the water ran out of the land into the drain as pure as spring water. As a proof of this, in the low districts of Scotland, where there was a scarcity of water, the inhabitants found that they could obtain as much water as they required from these drains, and that it was quite palatable and fit for domestic purposes. He had become quite convinced of the great superiority under-draining had over any other system. He would only draw their attention to the present season to prove this. It had been, he believed, the driest since 1826, and he had been at some pains in making inquiries as to the state of the plant when the lands had been thoroughly drained, and he found one uniform result, that the plant had continued to grow, and was as vigorous and healthy as in years when there had been a large quantity of rain. That distinctly showed the advantage of the system. He would next advert to the distance which it was expedient to make between each drain, and after careful investigation and much experience, he found that in the stiffest clay soils the distance ought not to be more than 18 feet from drain to drain: that would be found to suit most soils. In some parts of Scotland he had known them to have as large a space as 40 feet between the drains, but in those cases the land had been generally found to be wet at the extreme points between the drains, and the consequence was, that it had been found necessary to make a drain between the two. In Scotland the most incalculable benefit had been derived from the drainage on the clay lands; in many cases they had begun to grow Mangold Wurzel, which it had been found impossible to cultivate previously; this of itself was of great importance to the farmers, and if this system of draining were adopted in England, large crops of Turnips might be grown where none could be before, and particularly of Mangold Wurzel, because, although the attempt had been made to grow them in Scotland, they had not suitable climate, and that they had in England. One thing he would urge them to bear in mind with reference to drainage, and that was the necessity there was for their having a good level and a good outfall; if the brooks into which the water was to be discharged from the drain were insufficient for that purpose, great evils might arise from it; he had seen an instance in which a fall at the rate of 6 inches in a mile threw out 300 tons of water an hour. He divided drains into three denominations—main drains, sub-drains, and minor drains; and it ought always to be observed, where these discharged into each other, that the sub-drain should be 6 inches deeper than the minor drain, and the main drain one foot lower than the sub-drain. Another "great point also to be attended to was the constructing the drains in a regular manner. The parallel drains were decidedly the best, and a plan ought always to be kept in order to know the exact position of each drain; this was only to be accomplished by laying them down in a systematic manner. Some persons had agreed that the cross drains were the best; but as they must all terminate in a parallel drain, he thought it must follow that they should all be constructed on that principle. Mr. Smith then spoke of the manner of executing drains. In filling the drain with stones (which are better than tiles when they could be obtained for the same money), care should be taken that the stones were small and well selected. The depth of stones required he once thought was 12 inches, but from experience he now found that 8 or 9 inches were sufficient; consequently one-third of the quantity of stones originally used would now be saved. Care should be taken that the stones were well covered over with turf cut as thin as is used for thatching houses; and that the stones were completely covered from side to side; the turf should be covered over with 3 or 4 inches of soil taken from the bottom of the drain, because the more sterile its quality the better. He had executed 130 miles of draining within the last 30 years; he had since opened those drains in hundreds of places, all of which had been constructed according to the method he had described, and in not one single instance had he found any sediment between the stones. In many parts of England the expense was so great that it was found necessary to use tiles, and he did not object to them, particularly on clay-land; and they ought also to bear in mind that the tiles should never be put down without soles, because that enabled the cylinder to bear a much greater degree of pressure, and had been found in every respect much more efficacious. Mr. Smith next adverted at some length to the price, and more particularly to the construction of tiles; he declared himself to be of opinion that tiles were much the best without any holes in them, but expressed a hope that ere long a tile answering every purpose would be invented and made at a comparatively trifling cost. He had once advocated the system of putting stones over the tiles, he now found that there was nothing better than to trample clay which had been taken from the bottom of the drain firmly over them; that would be found not only sufficient to keep them in their places, but they would bear almost any weight. Mr. Smith then referred to the disposition of the surplus soil—but with this matter every agriculturist will be quite familiar—and proceeded to remark on subsoil-ploughing. The object of this was, he said, to move the sterile soil under the active soil, to free it from the water, and in time to bring it into such a state that it might be an adjunct, and, in fact, form a part of the active soil already possessed. He tried various methods to accomplish this object, and at length he got a plough made of 3 cwt., and with it ploughed 200 acres of land of his own; all his neighbours had used it; it had been in use upwards of 20 years, and had never been sent to the blacksmith's consequent on any serious derangement of the machinery, and it had turned up stones of 2 cwt. Subsoil-ploughing, as they were all aware, was merely to stir up the under soil at first, and not to throw it up; no farmer could succeed except he had a deep soil; he began farming with a soil varying from 2½ to 4 inches in depth, but after under-draining and subsoil-ploughing, he had had for the last ten years, 16 inches of mould; this was on what had previously been one of the most sterile farms that was to be met with. The subsoiling might be commenced carefully a year after draining; the first crop after draining should be Oats, and then they might begin to subsoil-plough, but it would be necessary that the work should be done cautiously. He had been asked whether subsoil-ploughing might take place before the land was drained; his reply was, that it would be very dangerous, because if an opening were made before there had been a regular course of draining, it only made a pool to hold more water. But of all things he cautioned them that the utmost care should be used in subsoil-ploughing for the first three or four years after draining. Several questions were put to Mr. Smith by Mr. Baker and other gentlemen. He said, in reply to one question, "Straw or stubble will do to put on the top of tiles on clay soils;" in reply to another, "It is improper to place light soil on the top of them;" and to a third, "It is possible, and in fact quite practicable, to drain with peat;" to a fourth, "I recommend land to be laid flat after thorough-draining;" and to a fifth, "I would not lay the land level until after the subsoiling had taken place.—*Abridged from Worcester Chronicle.*

Miscellaneous.

* *Thorough Draining.*—Mr. Aiton says—"In all clay soil and dense land the water does not filter beyond the depth of the plough furrow, unless the subsoil has been opened by trenching or subsoil-ploughing." Also, "In such land, if a pool be dug within 18 inches of the drain, and 30 inches in depth, when filled with water not a drop of it will (if the subsoil has not been rent in forming the pool) filter from the pool to the drain, but stand there until it is exhaled in vapour, by the sun, and by dry winds." The whole of these opinions have proved to be erroneous. I have found that the water does filter through the unbroken subsoil of dense clay, and that it does flow out of such pools as Mr. Aiton speaks of, to the drains. My proofs:—During the past season I opened 93 pools, and made observations for the purpose of tracing the rise and fall of the waters therein during the various changes from wet to drought, and the contrary in unbroken and broken subsoil. I have found that, in heavy blue adhesive clay, in which not the slightest porosity seemingly existed, the water was carried or filtered through the subsoil to the drains 24 feet on each side; and in less tenacious subsoils as far as 30 feet; and when the subsoil was broken, the distance from which the water was drawn was increased; but the great observable difference of effect lay in the shorter time in which it filtered to the drains. I formed the pools at right angles to the drains, at intervals of 6 feet asunder. I submit short comparative extracts from my registry:—

Experiment, No. 1.—Soil, thin blue clay on a heavy blue adhesive subsoil. The depth of the surface of the water in the pools is marked in inches.

Line of pools marked*							Weather, &c.
* 15	* 10½	* 4½	* 2½	* 2	* 2½	* 3½	26th October—10 o'clock, A.M. On the 24th, heavy showers; the 25th dry, with bright sun. Night wet.
2	1½	full.	full.	2	1½	3	28th Oct.—10, A.M. Previous day and night and this morning characterised by heavy and almost continuous rain.
13½	8½	2½	2½	3½	3½	3½	30th Oct.—Half-past 8, A.M. Part of 28th very heavy rain. Remainder of period to this date cold, frosty, and dry.
13	8½	4½	3½	1	1½	½	Rise during the wet period.
11½	6½	6½	2½	1½	2½	½	Fall during the dry period.

Experiment No. II.—*Soil*—Strong heavy clay, incumbent on a close, compact, reddish subsoil, intermixed with blue clay, and less retentive than No. I. The pools when made were at a distance from any of the drains then formed. The drain with which these observations are connected was opened 21st Oct. 1844. Thus the depth of water, and of course the effect, is observed by the comparison below.

Line of Pools marked *						Date of Registry, Weather, &c.
* 8	* 5	* 9	* 7	* 6	* 6	19th Oct. 7 A.M.—Warm sun, but little drought.
5½	4	7	5	4	4	21st Oct. 7 A.M.—Heavy rain for 3 or 4 hours, remainder of time mild but little drought.
11	3½	6½	6½	4½	5½	23rd Oct. 9 A.M.—Commenced [illegible] previous evening at 8 P.M.; heavy this morning, and ceased at 8 A.M.
11½	5½	8	7½	4	5½	25th Oct. ¼ past 7 A.M.—Heavy showers during the previous 24 hours.
13½	5½	7	6½	4½	4½	26th Oct. 9 A.M.—Heavy rain on [illegible] with during half the day; 27th dry, with bright sun—night wet.
13⅝	7½	10½	8½	6½	5½	27th Oct. ¼ past 7 A.M.—Previous day and night dry and frosty.
6½	1	4½	2½	2	3½	28th Oct. ¼ past 10 A.M.—Previous day and night heavy and continuous rain.
11½	10	12½	10½	8	7½	31st Oct. 8 A.M.—The 29th very wet; remainder of period, drying and a little frosty.
Comparison of draining effects, in unbroken Subsoil.						
6	6	5½	8½	4	3½	Fall from 21st (the day on which the drain was opened) to the 31st October.
0½	0	1	1	0	2	Fall from 8th to 21st October, previous to the drain being opened.

The above shows distinctly that the water was drawn off to a distance of 24 feet from the drains, and the fallacy of Mr. Aiton's statement, that "the water does not filter through the unbroken subsoil;" also, that "it *does not* lodge in the pools until exhaled in vapour by the sun," &c. It cannot be alleged that the subsoil was rent in digging the pools. The subsoil was unbroken, and yet the water passed off quickly; and even if the subsoil had been partially rent, the distances from which the water was drawn, on the drain being opened, proves distinctly that it percolates through the unbroken subsoil. If the operation of opening a pool 12 or 15 inches square had rent the subsoil, it could only have been a few inches around it; but this idea is absurd, as the tendency of such operation is to consolidate and render the pools more retentive of water. The following comparison shows more clearly the effect made at a distance from which the water is drawn off. One part of the ground unbroken, and the other trenched 18 inches deep:—

Line of Drains.	* Line of Pools marked *						Date of Registry, &c.
	* 14	* 12	* 12	* 14½	* 13	* 13	Trenched — 26th Nov. 8 A.M. Weather mild, but very little drought.
	9	6	9	7	4	4	Untrenched
	15	11½	12	14	14	11	Trenched — 15th Dec. 8 A.M. Previous three or four days very drying.
	15	11	13½	12	9	9½	Untrenched
	10	9½	9	9½	10½	10½	Trenched — 21st Dec. 8 A.M. Rain during the previous night.
	15	9	9½	9	6½	6½	Untrenched

There are some apparent discrepancies in this comparative registry, but arising principally from some of the

* These figures express the distance in inches of the surface of the water in the pools from the surface of the ground; the depth, in fact, which the water had sunk in the pools.

pools lying in hollows or furrows, on which Mr. Aiton relies, as on a broken road, for drawing off the surface water. From these it is evident that the water percolated from the fourth pool, or 24 feet, after which, the difference in rise and fall of the waters leaves not the shadow of a doubt as to the result, although the contrary is so confidently asserted by Mr. Aiton. A comparison of the trenched and the untrenched proves the greater distance from which the water is drawn in the former; and I know that it would be carried from a much greater distance if the land was subsoiled as it was drawn off from the extreme of the part trenched deep.—*John McArthur, in the Ayrshire Agriculturist.*

African Guano.—A friend has favoured us with the following analysis, by Mr. R. Phillips, *of* a sample of African Guano submitted to that excellent chemist for examination:—

Ammoniacal Salts, containing 7½ of ammonia and organic animal matter	46.0
Phosphate of Lime, &c.	19.8
Fixed Alkaline Salts	4.2
Sand	4.0
Water	26.0
	100.0

Artificial Manures.—Experiments with Artificial Manures, tried by T. C. Eyton, Esq., at Donnerville, near Wellington; Seed, Swedish Turnips, obtained from Skirving's, Liverpool. Sown on the 17th of May, 1843; pulled and weighed on the 23d of November.

No.	Description of Manure.	Cost per Acre.	Weight of Crop per acre.	Measure per acre.	Cost of Manure per bushel of crop.
		£ s. d.	ton. cwt.	bush.	d.
1	168 lbs. of Mur. Ammon. + 220 lbs. of Gypsum	1 10 11	7 1¼	154	2¼
2	330 lbs. of Guano	1 13 0	15 1	308	1¼
3	168 lbs. of Mur. Ammon.	1 6 6	8 16	192½	1½
4	330 lbs. of Guano + 220 lbs. of Gypsum	1 17 5	15 14½	346½	1½
5	330 lbs. of Guano + 11 bush. Wood-ashes	3 4 0	17 7½	423½	1½
6	168 lbs. of Mur. Ammon. + 11 bush. Wood-ashes	1 17 6	14 19½	385	1½
7	1322 gals. Liq. Manure, viz., Urine & Soapsuds	——	11 0½	269	—
8	66 lbs. of Bones + 8½ qts., or 33 lbs., of Sulphuric Acid + 550 gallons of Water	0 8 8½	14 6	346½	¼
9	484 lbs. of Bone-dust	1 1 7½	14 19½	308	2

Remarks.—In the above calculation fractional parts are not included: the following is an analysis of the subsoil. I was told by a former tenant of the field that it would not grow Turnips; it was, however, drained shortly before the Turnips were sown.

One hundred parts of the soil contain—

Water	11 parts.
Silica or Sand	70 ,,
Alumina or Clay	15 ,,
Red Oxide of Iron	1.5 ,,
Carbonate of Lime	1.5 ,,
Loss	1 ,,
A trace of Sulphate of Lime in weight not appreciable.	
	100

The proportion of silica is that yielded by the soil after the largest stones or pebbles had been removed from it. The Turnips all came up together, nor was there any perceptible difference in their appearance on the 27th of May; on the 14th of June No. 2 appeared to take the lead, 1, 7, 8, looking the worst, and being more backward than the others; on June the 30th they were horse and hand-hoed, Nos. 9, 10, 8, 4, 5, were equal in appearance to No. 2; on July 21st, No. 5 looked best, No. 1 the worst of all.—*From a Lecture by T. C. Eyton, Esq., to the Wellington Farmers' Club.*

Water Meadows, Hampshire.—These meadows are copiously irrigated by the bright chalk waters of the Itchen, a river whose waters are, perhaps, the most copious, considering the shortness of its course, of all the southern English rivers. The farmer who views the mass of crystal water, pouring under Winchester bridge, will hardly feel inclined to suspect that all this flood is the produce of a few springs which arise within seven miles of the city. When the farmer also notices the fertility diffused by the use of these bright waters—waters which contain such very limited proportions of either earthy, saline, or organic impurities, he will feel assured that it is an error to conclude that it is only very impure waters that are valuable for the use of the irrigator. It is, in fact, a mistake which most persons make, to suppose that even these bright and transparent waters are perfectly pure, and that they do not contain any substances which are the food of plants—for both these popular opinions have been proved to be erroneous. Thus, the waters of the Itchen contain, in 10,000 parts, 2½ parts of solid matter, viz.—

Organic matter	0.20 parts.
Carbonate of lime (chalk)	1.89 ,,
Sulphate of lime (gypsum)	0.72 ,,
Muriate of soda (common salt)	1.01 ,,

Now, that these saline substances are absorbed by plants, from these kinds of irrigation waters, has been shown by Dr. Madden ("Trans. High. Soc." vol. viii. p. 687), who found, in a gallon of the water of some springs issuing from the foot of the Pentland Hills, of

Carbonate of lime (chalk)	4 grains.
Chloride of sodium (common salt)	10 ,,

But after this water had been passed over some meadows, it was found to contain these salts in diminished proportions. The same quantity of water then contained, of

Chalk only	2 grains.
Common salt	5 ,,

Such facts would appear to confirm the conclusions of some of the ablest cultivators, that the chief advantages of irrigation are attributable to the foreign substances with which the water is charged; although, as we have elsewhere observed, almost every farmer has a mode of accounting for the highly fertilising effects of irrigation—one thinks it cools the land, another that it keeps the Grass warm in winter. And this was Sir H. Davy's opinion. He thought that a winter-flooding protected the Grass from the injurious effects of frost. In these conclusions with regard to the theory of irrigation, we have found many excellent practical farmers concur. Thus, Mr. Simonds, of St. Cross, near Winchester, considers that the great benefit of winter flooding for meadows is derived, in the first place, from the deposits made by the muddy waters on the Grass; and, secondly, from the winter covering with water preventing the ill effects to the Grass of sudden transitions in the temperature of the atmosphere. This gentleman is perfectly aware of the value of the addition of the city drainage of Winchester to the fertilising qualities of the Itchen river water, and of its superiority for irrigation after it has flowed past the city, having watered meadows both above and below the town; and he finds that if the water has been once used for irrigation, that then its fertilising properties are so materially reduced that it is of little value for again passing over the meadows; and so convinced is he, by experience, of this fact, that, having in this way long enjoyed the exclusive and valuable use of a branch of the waters of the Itchen for some Grass land, a neighbour higher up the stream followed his example, constructing some water meadows, and using the water before it arrived at those of our informant, who, in consequence, found the water so deteriorated in quality (though not sensibly diminished in quantity) that he once thought of disputing the right with his more upland neighbour. The experience of other irrigators tends to the same conclusion. In the best managed water meadows of Hampshire the farmer does not procure annually more than three crops of Grass; yet in situations where a richer water is employed, as near Edinburgh, four or five are readily obtained.—*From Mr. Johnson's Register of Implements, Southampton Show.*

Notices to Correspondents.

Rural Chemistry. By Edward Solly, Esq., F.R.S., Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, has been reprinted from the *Gardeners' Chronicle*, with additions, and may be had of all booksellers, price 4s. 6d.

Books.—*D. L. B.*—Lectures on "Agricultural Chemistry and Geology," by Professor Johnston. With regard to your tanks, its contents, if the ammonia in them be fixed, should be used on land a fortnight before sowing Corn in spring; or you may put it on your young crops of Wheat or Grass in April.—*Cestriensis W.*—Thank you for your communication—we may, perhaps, hereafter make use of it, and shall be very glad to receive the results of your experiments on Potatoes.

Burning Clay.—*B.S.*—See a tract on this subject published in 1830—"Practical Hints on Burning Clay," by C. Poppy.

Disease in Pigs.—*Holby Bank.*—This disease is of the nature of palsy, and produced most probably by cold. Give 1 dr. of gentian, ½ dr. of ginger, ½ dr. of spirit of nitrous ether, in a little gruel, and repeat, if necessary, the following day. *W. O. S.*

Manure.—*H. A. S.*—Sulphuric or muriatic acid is the most certain fixer of ammonia. The price should determine your preference of either. With regard to its use, see two or three articles on "Fixation of Ammonia," in Nos. 26 and 27 of this Paper, and sprinkle the *diluted* acid over the manure in the yard.

Newspaper.—*A.B.C.*—The subscription is 6s. 6d. per quarter, *if paid in advance.* If you cannot get the Paper supplied you at this rate our own agent will send it you. Thanks for your paper; you are quite right.

Prof. Johnston.—*S.*—We shall answer next week.

Rabbits.—*J. P.*—The tenant of lands, or any person by his direction or command, may take or destroy rabbits on such lands without taking out a Game Certificate, and that either with a gun or in any other manner. See Exceptions to the Duties in Schedule L. of 52 Geo. III. c. 93. *W.*

Smother Burning of Peat.—*W. Bartlett.*—Will Mr. Parkes' Paper, in a former Number, on Peat-Charcoal answer your question?

Steeping Seeds.—*A Subscriber.*—Lime will dry your seed, but it will tend to decompose the substance in which it has been soaked. Charcoal dust might dry it, but probably if you steep on a large scale, practical difficulties might exist in the way of its use. What we soaked was *hoed in* wet, half-an-hour after being taken out of the water. You must not soak except in a very weak solution so long as 60 hours—at least our experience proves the danger of the practice. We should be glad to know the results of your experience in steeping seeds.

Turnips.—*W.* hopes that the Earl of Essex will kindly hereafter report the result of his lordship's interesting experiment, so as to ascertain the effect on the ripened crop of the manures applied.

***As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, July 22.—Per stone of 8 lbs.

Best Beasts, Herefords, &c.	3s	8	to	4s	0	Best Downs & Half-breds	3s 10 to 4s 2
Best Short Horns	3	2		3	6	Best Long-wools	3 6 3 10
Second quality Beasts	2	10		3	2	Kows and second quality	3 2 3 6
Calves	3	8		4	2	Lambs	4 4 5 0
Pigs	3	0		3	8		

Beasts, 2580; Sheep and Lambs, 22,980; Calves, 193; Pigs, 350.

We have a very fair supply of Beasts to-day, and in tolerably good condition. Trade is not very brisk, especially for large coarse Beasts and second qualities, but the best beasts, &c. maintain their price, in some few instances 4s 2d per 8 lbs. has been obtained, and some of the very best Short-horns have made 3s 4d. The supply of Sheep is again large, but we are not over stocked with the best qualities, and there is still a large demand for keeping Sheep; thus, although the numbers have somewhat affected the trade, and made it a little worse than on Friday, it is not sufficiently so to make any alteration in our quotations. Good Lamb maintains the price, and is rather more in demand, but middling qualities are very difficult to dispose of. Veal and Pork are rather lower.

Friday, July 26.

We have a large supply of Beasts, and very little trade; the weather having been so excessively hot during the week has hindered the Butchers from killing. A large number must be turned out; what are sold suffer a reduction of fully 2d per 8 lbs from Monday. Our supply of Sheep is not very large, but quite adequate to the demand: the weather has also caused lower prices to be taken, especially for large Sheep: the most selling Downs make about 4s, and Longwools 3s 6d. We have a great deal of plain Lamb; the best quality is worth about 5s. There is a very large supply of Calves, and 4s per 8 lbs is quite the top price. Pork is about the same as on Monday.

Beasts, 773; Sheep and Lambs, 12,270; Calves, 300; Pigs, 263.

41, West Smithfield.

HOPS, Friday, July 26.

§ The parts of the plantations which have been severely attacked with vermin are completely gone into blight, and the opinions are not very favourable respecting the good district. There is no material alteration to notice in the Market, and the duty is laid at 145,000*l.*

Patterson & Sons, Hop-Factors.

WOOL.—British, Friday, July 26.

Do. Hoggets	1s 1		1 3	Kent Fleeces	1 1 1 3
Southdown Fleeces	11½		1 0½		

James Pearse, Wool Broker.

COVENT GARDEN, July 25.—In consequence of the late fine weather the market continues to be well supplied with vegetables of tolerably good quality. Fruit of all kinds in season is abundant. Fine Apples are good; they consist principally of Queens, with a few Montserrats, Ruvilles, and Providences. A considerable quantity of the imported varieties mentioned last week are still in the market; they are somewhat reduced in price. Of Hothouse Grapes there is a fair supply; Peaches, and Nectarines are very good. Apricots are for the most part small in size. Plums are pretty good, and are becoming more plentiful; they consist chiefly of Orleans, with a few Green Gages. Cherries are sufficient for the demand, but Strawberries are less abundant. Raspberries, Currants, and Gooseberries are offered in large quantities. Kitchen Apples are to be procured, but they are still small. Some good specimens of frame Cucumbers are in the market, which may be obtained at a low price. Peas continue to be brought in considerable quantities, and French Beans are sufficient for the demand. Carrots are good, but Turnips are rather inferior both in size and quality. Good Cauliflowers may be met with, but they are becoming scarcer. Cabbages are good and plentiful. Artichokes and Vegetable Marrows are not scarce. Salading and Herbs of every description are plentiful. Cut Flowers comprise Swainsona galegifolia, Lilium eximium, Bignonia venusta, Alstroemeria pelegrina, Ceanothus azureus, Heaths, Gladiolus, Pelargoniums and Gardenias, with Roses, Carnations, Picotees, Verbenas and Fuchsias, in great abundance.

FRUITS.

Pine Apple, per lb., 4s to 6s	Strawberries, per gallon, 1s 6d to 2s
Hothouse Grapes, per lb., 2s to 6s	Gooseberries, per bt.-sieve, 1s 6d to 4s

— Ridge, each, 2d to 3d	Green Mint, per bunch, 2d to 4d
Vegetable Marrow, per doz., 2d to 3s	Marjoram, per bunch, 4d to 6d
Spinach, per sieve, 2s to 3s	Chervil, per punnet, 2d to 3d

MARK-LANE, Monday, July 22.

The supply of English Wheat from Kent, Essex, and Suffolk this morning was moderate; notwithstanding which, sales could not be proceeded with, excepting at a decline of 2s. to 3s. per qr., at which reduction the stands were not cleared. For Foreign, the greatest difficulty was experienced in finding purchasers, even of retail quantities, at a decline of 1s. to 2s. per qr. on middling Red, and out of conditioned parcels a greater sacrifice would have been submitted to, to induce buyers to take a quantity, but they refrained entirely from touching these descriptions.—In Barley there is scarcely anything doing, and the tendency of prices is downwards.—The value of Beans and White Peas is unaltered, but Grey are 1s. cheaper.—Oats are a slow sale, and barely maintain their late quotations.

Friday, July 26.

The fine, hot, and favourable weather we have had for forwarding the harvest since Monday has caused a very dull trade for all descriptions of Corn: Millers refrain from purchasing, and we are consequently unable to quote the decline in Wheat, but holders would probably have accepted a farther reduction.—Barley, Beans, and Peas are nominally unaltered in value.—The Oat-trade is very heavy, and barely supports our quotations.

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of searching thoroughly into the divisions of the teeth, and cleaning them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose—1*s*. An Improved Clothes Brush, that cleans in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and successful manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the luxury of a genuine Smyrna Sponge. Only at METCALFE'S Sole Establishment, 130*a*, Oxford-street, one door from Holles-street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

BRIGHT'S CUSTARD COMPOUND. — The ORIGINAL VEGETABLE PREPARATION, for making custards without eggs. Patronised by the Royal family, Nobility, and Gentry, with the approval and testimony, amongst many others, of the COOKS to SIX CROWNED HEADS. Sold in boxes at 1*s*. and 4*s*. each. Manufactory, 5, Holland-street, North Brixton, Surrey. Wholesale of all respectable houses, and retail of by upwards of 1000 chemists, confectioners, grocers, Italian Warehousemen, &c., throughout the United Kingdom. Caution—Beware of imitations, and observe on all sent out the signature of the Inventor, JOHN BRIGHT.

STATE LOAN of His Royal Highness the Grand Duke of Baden of 5,000,000 fls., to be reimbursed with 9,034,055 fls., in lots of 50,000, 40,000, 35,000, 30,000, 20,000 fls., &c., the smallest being 50 fls.—GRAND PUBLIC DISTRIBUTION to take place at Carlsruhe on the 1st of August next; official bulletins containing the result will be forwarded immediately to every shareholder. Price of a single certificate, 10*s*.; 11 for 5*l*.; 23 for 10*l*.; 60 for 25*l*. sterling; payable in notes, money orders, or remittances.—Apply for full particulars and certificates, without delay, to Moriz I. Stiebel, banker, Frankfort-on-Maine. To save postages, all letters addressed to Messrs. Stiebel and Co., 8, Lime-street, London, will be promptly forwarded and attended to.

THE BEST ENGLISH WATCHES.—A. B. SAVORY and Sons, Watchmakers, 9, Cornhill, London, opposite the Bank, request the attention of purchasers to their stock of London-made PATENT LEVER WATCHES, which are manufactured by themselves, in their own house. In silver cases, with the detached escapement and jewelled, the prices are four and a half guineas, six, and eight guineas each; or in gold cases, 10, 12, 14, and 16 guineas each. The very large stock offered for selection includes every description, enabling a customer to select that which is more particularly adapted to his own use.

ROWLAND'S ODONTO, OR PEARL DENTIFRICE, patronised by "Her MAJESTY," H.R.H. Prince ALBERT, the Royal Family, and the several Courts of Europe. A FRAGRANT WHITE POWDER, prepared from Oriental Herbs of inestimable virtue, for strengthening, preserving, and cleansing the teeth. It eradicates the factitious formation of tartar, and by the removal of that extraneous substance lends a salutary growth and freshness to the gums. It removes from the surface of the teeth the spots of incipient decay, polishes and preserves the enamel, substituting for discolour and the aspect of impurity, the most pure and pearl-like whiteness; while, from its salubrious and disinfecting qualities, it gives sweetness and perfume to the breath, bestowing at once cleanliness, and the appearance and reality of health. Price 2*s*. 9*d*. per box, duty included.

Caution.—To protect the public from fraud, the Hon. Commissioners of Her Majesty's Stamps have authorised the Proprietors' Signature to be engraved on the Government Stamp thus,—A. ROWLAND and SON, 20, Hatton Garden, which is affixed to each Box. Ask for ROWLAND'S ODONTO. Sold by them, and by Perfumers and Chemists.

*** All others are SPURIOUS IMITATIONS.

EXTIRPATION of all kinds of VERMIN.—Office, 69, King William-street, city, London. — Mr. J. A. MEYER, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Gallcy Quays and warehouses in Lower Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5*s*., 10*s*., 20*s*., 50*s*., and 100*s*. each, with full directions, which must be used in proportion to the extent of premises infested; to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling-houses cleansed from 1*l*. to 5*l*. per annum; mansions and estates from 10*l*. and upwards; ships, docks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

MR. HOARE'S NEW WORK ON THE VINE:
This Day is published, 12mo. 5*s*. cloth,
A DESCRIPTIVE ACCOUNT OF A NEW METHOD of PLANTING and MANAGING the ROOTS of GRAPE VINES. By CLEMENT HOARE, Author of "A Treatise on the Cultivation of the Grape Vine on Open Walls."
London: Longman, Brown, Green, and Longmans.

MAVOR'S SPELLING-BOOK.
THE ONLY GENUINE EDITION.
With the Author's final Corrections and Improvements.
Messrs. Longman and Co. respectfully acquaint Booksellers and Conductors of Schools, that they have just published the 451st edition of Mavor's Spelling-Book, with the various revisions and improvements of Dr. Mavor. New types have been cast for it, and it is also illustrated by a Frontispiece, after Stothard, and Forty-four beautiful Wood Engravings, designed expressly by Harvey, which render this edition of Dr. Mavor's long-established and superior Spelling-Book the most attractive of any in existence.
London: LONGMAN, BROWN, GREEN, and LONGMANS.
Sold by all Booksellers in Town and Country.

CROCKER'S LAND-SURVEYING IMPROVED.
Just published, post 8vo., with very numerous Diagrams, a Field-book, Plans, &c. &c. 12*s*. cloth,
CROCKER'S LAND-SURVEYING.—New Edition, corrected throughout and greatly improved, by T. G. BUNT, Land-Surveyor; with Tables of Six-Figure Logarithms, superintended by R. FARLEY, of the Nautical Almanac Establishment.
The LOGARITHMS separately, 4*s*. 6*d*. cloth.
London: LONGMAN, BROWN, GREEN, and LONGMANS.

NEBBIT'S MENSURATION IMPROVED.
Published this Day, 12mo, 6*s*. bound,
A TREATISE on PRACTICAL MENSURATION, containing the most approved Methods of Drawing Geometrical Figures; Mensuration of Superficies; Land Surveying; Mensuration of Solids; the Use of the Carpenter's Rule; Timber Measure, in which is shown the Method of Measuring and Valuing standing Timber; Artificers' Works illustrated by the Dimensions and Contents of a House; a Dictionary of the Terms used in Architecture, &c. By A. NEBBIT. Twelfth Edition, enlarged and greatly improved, with nearly 700 Practical Examples, and nearly 300 Woodcuts.—KEY. Seventh Edition, 12mo, 5*s*. bound.
London: LONGMAN, BROWN, GREEN, and LONGMANS.

HAND-BOOKS FOR THE PEOPLE.
THE HAND-BOOK OF GARDENING; expressly intended for Persons possessing and fond of cultivating a Garden of moderate size. Price 2*s*. cloth, a New and Enlarged Edition.
THE HAND-BOOK OF BOTANY;
Or Linnæan Lessons on Common Plants, for Field and Garden Practice. Price 2*s*.
THE HAND-BOOK OF AGRICULTURE;
Chiefly for the use of those interested in the Allotment System. Price 1*s*. 3*d*.
THE HAND-BOOK OF COOKERY;
Intended for the use of the Middle Classes. Price 2*s*. cloth.
THE HAND-BOOK OF THE TOILETTE;
Having in view the union of Bodily Health with Beauty of Person. Price 2*s*. cloth.
THE HAND-BOOK OF THE LAUNDRY;
Expressly intended for those who "wash at home." Price 1*s*. 9*d*.
THE HAND-BOOK OF MEDICINE;
Forming a Useful Manual in time of Need, when Professional Aid cannot readily be procured. Price 2*s*. cloth.
THE HAND-BOOK OF NATURAL PHILOSOPHY.
Price 1*s*. 9*d*.

Bound in cloth, price 5*s*. 6*d*.
JOE MILLER'S JEST-BOOK.
A Reprint from the first and genuine Edition, such omissions and alterations only having been made as were required by the greater delicacy observed in modern conversation; but, that the volume might have some substance, and be a good table or travelling book, copious additions have been made from other old volumes of Facetiæ.
Extract from the Preface.
"Another strange circumstance connected with this work is, that everybody presumes that he himself and everybody else are perfectly familiar with its contents . . . and yet, if the reader will ask his acquaintance, it will appear that not one in five hundred ever set eyes on a copy. It is in consequence of like questions that this edition is published."
London: WHITTAKER and Co.

Now ready, price 4*s*. 6*d*.,
RURAL CHEMISTRY.
By EDWARD SOLLY, Esq., F.R.S.,
Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry, at the Royal Institution.
&c. &c. &c.
Extracts from the Introduction:—
"A knowledge of the chemical composition of soils and the various substances employed as manures enables us to comprehend the mode in which the latter act; and a knowledge of the nature of those substances which plants require, points out the best and most economical methods of restoring to the soil, by manures, those substances which plants remove from it."
"If the farmer knows what it is that gives the fertilizing powers to manure, and is aware of the nature of those substances, he will soon learn the best method of preserving and using them: he will then understand how to make the most of the various sources of manure at his disposal, and he will be enabled readily to save much, that, for the want of such knowledge, would otherwise be lost."

Patients, Perry and Co. may be consulted daily at their residence, 52, Berners-street, Oxford street, from 11 till 3, and from 5 till 8. On Sunday, from 10 till 12.

This day is published, complete in one large volume 8vo, price 24s.,

LECTURES ON AGRICULTURAL CHEMISTRY and GEOLOGY. By JAMES F. W. JOHNSTON, M.A., F.R.S.S.L. & E., &c. &c. Chemist to the Agricultural Chemistry Association of Scotland, and Reader in Chemistry and Mineralogy in the University of Durham. With an APPENDIX, containing Suggestions for Experiments in Practical Agriculture.—WILLIAM BLACKWOOD and SONS, 45, George-street, Edinburgh; and 22, Pall Mall, London.

IMPORTANT AGRICULTURAL WORKS, published by JAMES MUDIE, Piccadilly; and to be had of all Country Booksellers in every Market Town.

1. PERUVIAN and BOLIVIAN GUANO, with Practical Instructions for its use, and testimonials of its [illegible], price 2s.

2. A Fourth Edition, enlarged, of MORTON on SOILS and their KENT and PROFITS of AGRICULTURE. Price 10s.

3. On MANURES, by CUTHBERT W. JOHNSON, Esq., F.R.S.; a New Edition greatly enlarged. Price 10s, bound in cloth.

4. SINCLAIR on GRASSES and the WEEDS of AGRICULTURE. A New Edition, with numerous coloured Plates [illegible] cloth.

5. JOHNSON'S TRACTS for AGRICULTURAL SCHOOLS Price 1s. each:—

THE COTTAGE-FARMER'S ASSISTANT—CALENDAR for YOUNG FARMERS—and AGRICULTURAL CHEMISTRY for YOUNG FARMERS.

In the Press, VON THAER'S PRINCIPLES of AGRICULTURE. Translated by W. SHAW, Esq., in 2 vols. Price 25s cloth.

HOOD'S MAGAZINE for AUGUST contains Editorial Cuts on topics of the day (in the "Comic Annual" style), and two Chapters of Hood's New Novel "Our Family;" also Contributions of various interest, by G. P. R. James, R. Monckton Milnes, M.P., T. O. Ward, R. Browning, Alfred Wigan, the Author of "Ireland and its Rulers," Dr. Stoddart Mackenzie, [illegible], Gliddon Shadrac, the Mountaineer, Miss Catherwood, &c. An article on the "Leader of the Opposition," by the Author of "The Examiner," in the last Number, will be given, and a Sketch of the Polish is especially commended to the study of the Times Leader. Sir Edward Bulwer Lytton, Bart., will write in the next Number.—HENRY RENSHAW, 356, Strand, and all Booksellers.

RENDLE'S TANK SYSTEM OF HEATING.

In consequence of the increasing demand for RENDLE'S "TREATISE ON THE TANK SYSTEM," a Third Edition has just been published, and can now be obtained of the Author, 19, of the Asylum, at Plymouth.

London: Longman, Brown, Green, and Longmans.

Price Eightpence, Free by Post Sixpence,

The Lancet,

Of Saturday last, July 22, contains:

A COURSE of LECTURES on ORGANIC CHEMISTRY, Delivered in the University of Giessen, by PROFESSOR LIEBIG —

The Theory of Acids.

On the Errors and Mischiefs of the Sound and Catheter, and on the Nature and Treatment of Urinary Stricture, by T. Wilkinson King, Esq.

The Periods Regulating the Recurrence of Vital Phenomena, by Dr. T. Laycock.

Congenital Fissure of the Iris, by Dr. C. T. Mackin

Case of Ovarian Dropsy, in which Tapping was performed Seventy-eight times, by J. C. Atkinson, Esq.

Practical Observations and Suggestions, by Dr. Marshall Hall —On Inducing Warm and Moist Atmosphere in the Sick Room, &c.

Practical Facts and Observations on Diseases of Women, and some Subjects connected with Midwifery, by G. O. Heming, M.D.—On Uterine Polypus.

Case of Phlebitis terminating Fatally in Twenty-four Hours, by J. Bernasconi, Croydon.

Answer to the Remarks of a Writer in the Medical Gazette, on the Functions of the Spinal Marrow, by M. B.

BRITISH AND AMERICAN MEDICAL JOURNALS —

The Soft Cecipat; its Nature and Symptoms. The Infirmary for Diseases of the Rectum. Inhalation of Oxygen Gas as an Antidote to Poisoning with Carbonic Acid. Tartarsmetic a Remedy for Syphilis. Death from Rupture of the Lung. Influence of a Varying State of the Price of Provisions on Disease and Mortality. The Microscopical Characters of Milk. American Medical Students. The Sedative Powers of the Argot of Rye. The Nature of the White or Opake Serum of Blood. The Symptoms of the Second Stage of Cancer in the Stomach. The Employment of Electro-Puncture in Neuralgia.

CHEMISTRY, PHARMACY, AND MATERIA MEDICA —

Dumas' Chemico-Physiological Theories.—Theory of Respiration. Inorganic Constituents of Vegetables. Presence of Fluorine in Bones. Mineral Marmoratum, or Paste, to fill Hollow Teeth. Tooth Powders. Test for Arsenic.

Pauper Lunatics in Workhouses.—Clinical Instruction in Hospitals.

HOSPITAL REPORTS —

UNIVERSITY COLLEGE HOSPITAL.—Strangulated Femoral Hernia of Two Days; Operation. Death. Strangulated Femoral Hernia of several days; Operation. Cure. Strangulated Inguinal Hernia, Operation; Abscess of Sac, Cure.

LONDON HOSPITAL.—Dense Cyst filled with Fluid occupying the Position of a Psoas Abscess.

CHELTENHAM GENERAL HOSPITAL.—Fracture of the Skull attended with External Pulsation.

Statement of the Society of Apothecaries.

The late Inquest at Lambeth again.

Examinations at the University of London.

Remarks on Lectures and Hospital Practice.

Clinical Lecturing in Hospital Practice.

On the Value of Sulphate of Iron as an Antidote in Poisoning by Prussic Acid.

MEDICAL SOCIETIES —

ROYAL MEDICO-BOTANICAL SOCIETY.—On Atropa Belladonna.

News of the Week—Apothecaries' Hall—Mortality Table—Correspondents.

SCHOOL AND COLLEGE BOOKS,

Printed for LONGMAN, BROWN, GREEN, AND LONGMANS.

1

ENGLISH; or, the Art of Composition explained in a Series of Instructions and Examples. By G. F. GRAHAM. 2d Edition, fcp 8vo 7s

2

HELPS to ENGLISH GRAMMAR; or, Easy Exercises for Young Children. By G. F. GRAHAM, Author of "English; or, the Art of Composition." 12mo. with Wood Engravings, 3s.

3

FIRST STEPS to LATIN WRITING: intended as a Practical Illustration of the Latin Accidence. To which are added, Examples on the principal Rules of Syntax. By G. F. GRAHAM. 2d Edition, improved, 12mo 4s

4

A PROGRESSIVE GRAMMAR of the LATIN LANGUAGE, for the Use of all Classes in Schools. By the Rev. B. H. KENNEDY, D.D., Head Master of Shrewsbury School. 12mo 4s 6d

5

LATIN GRAMMAR PRACTICE. 1. Lessons in Vocabulary; 2. Latin, made out of each column for translation; 3. English for retranslation. By the Rev. JAMES PROPOFT, B.A. 12mo 2s. 6d.

6

GREEK GRAMMAR PRACTICE. 1. Lessons in Vocabulary; 2. Greek, made out of each column for Translation; 3. English for retranslation. By the Rev. JAMES PROPOFT, B.A. 12mo. 3s 6d

7

AN ELEMENTARY GRAMMAR of the GREEK LANGUAGE. By Dr. RAPHAEL KUHNER, Co-Rector of the Lyceum, at Hanover. Translated by J. H. MILLARD, St. John's College, Cambridge. 8vo 9s.

8

MAUNDER'S UNIVERSAL CLASS-BOOK: a New Series of Reading Lessons (original and selected) for Every Day in the Year; with Questions for Examination. By SAMUEL MAUNDER, Author of "The Treasury of Knowledge," &c. 2d Edition, 12mo. 5s

9

AN ELEMENTARY TREATISE on ALGEBRA, Theoretical and Practical. By JAMES THOMSON, LL.D., Professor of Mathematics in the University of Glasgow. 12mo. 5s.

10

ELEMENTS of NATURAL HISTORY, for the use of Schools and Young Persons. By MRS. LOUDON (formerly Mrs. T. E. BOWDICH), Author of "Tales of Travellers," &c. 12mo with 48 Woodcuts, 7s. 6d.

11

HAMEL'S FRENCH GRAMMAR and EXERCISES. A New Edition, in One Volume, improved and enlarged. By F. CLAUDIUS, 12mo. 5s. 6d.

London: LONGMAN, BROWN, GREEN, AND LONGMANS.

NOW PRINTED FOR

TAYLOR AND WALTON,

28, UPPER GOWER STREET.

LIEBIG'S AGRICULTURAL CHEMISTRY.

Third Edition, Revised and partly re-written. 8vo. 10s. 6d., cloth.

CHEMISTRY in its APPLICATIONS to AGRICULTURE and PHYSIOLOGY. By JUSTUS LIEBIG, M.D., F.R.S., Professor of Chemistry in the University of Giessen. Edited, from the Manuscript of the Author, by LYON PLAYFAIR, PH. D.

"—a book infinitely superior to its predecessors, and to a very considerable extent unlike them."—*Gardeners' Chronicle.*

LIEBIG'S ANIMAL CHEMISTRY.

Second Edition. 8vo. 9s. 6d. cloth.

ANIMAL CHEMISTRY; or, CHEMISTRY in its APPLICATIONS to PHYSIOLOGY and PATHOLOGY. By JUSTUS LIEBIG, M.D. Edited, from the Author's Manuscript, by WILLIAM GREGORY, M.D., Professor of Chemistry in the University of Edinburgh.

"While we have given but a very imperfect sketch of this original and profound work, we have endeavoured to convey to the reader some notion of the rich store of interesting matter which it contains. The chemist, the physiologist, the medical man, and the agriculturist will all find in this volume many new ideas and many useful practical remarks. It is the first specimen of what modern Organic Chemistry is capable of doing for Physiology; and we have no doubt that from its appearance Physiology will date a new era in her advance."—*Quarterly Review*, No. 139.

LIEBIG'S CHEMICAL LETTERS.

Second Edition, Fcap. 8vo, 4s. 6d. cloth,

FAMILIAR LETTERS ON CHEMISTRY; AND ITS RELATIONS TO COMMERCE, MANUFACTURES, AND AGRICULTURE. By JUSTUS LIEBIG, M.D. Edited by JOHN GARDNER, M.D., Member of the Chemical Society.

"That the public will discover its merits, and that it will find its way into the drawing room as well as the library, and be equally prized by the advanced man of science and the student, we venture to say is certain; and it must increase the respect entertained for Chemistry wherever it is read."—*Chemical Gazette.*

CHEMICAL ANALYSIS.

One Volume 8vo, with numerous Diagrams, 10s 6d. cloth.

ELEMENTS OF CHEMICAL ANALYSIS, INORGANIC AND ORGANIC. By EDWARD ANDREW PARNELL, late Chemical Assistant in University College, London.

"In conclusion, we cordially recommend this work to those who are disposed to aid themselves in examining the constituents of their soils. Mr. Parnell deserves the best thanks of English chemists for his masterly work, and we earnestly hope that it will prove the means of elevating the analytical chemistry of our country—a branch of the science in which we have long been deficient."—*Farmers' Magazine*, Nov. 1843.

TURNER'S CHEMISTRY:

By Professors LIEBIG and GREGORY. Complete in 1 vol. 8vo, 17s. cloth.

TURNER'S ELEMENTS of CHEMISTRY. Seventh Edition. Edited by JUSTUS LIEBIG, M.D., F.R.S., Professor of Chemistry in the University of Giessen; and WILLIAM GREGORY, M.D., Professor of Chemistry in the University of Edinburgh.

"As a compendium of the present state of Chemistry, and a text book for all beginners, we consider it as unequalled by any in the English language, and we even doubt whether there are any of the foreign manuals of an equal size which can venture to compete with it."—*Chemical Gazette*, Dec. 1, 1842.

LINDLEY'S ELEMENTS OF BOTANY.

One vol 8vo, with many hundred figures on wood, 10s 6d cloth.

LINDLEY'S ELEMENTS OF BOTANY, STRUCTURAL, PHYSIOLOGICAL, SYSTEMATICAL, and MEDICAL; being a Fourth Edition of the Outline of the First Principles of Botany.

"This Work is indeed what the author intended it to be, 'A Complete Botanical Note-book, wherein all the principal topics which the teachers of Botany introduce into their lectures, are arranged methodically.' The necessity for such works as pegs for fixing facts in the memory, and giving them their full value on their application to reasoning processes, is undeniable; and between the skill of the author and that of the engraver, it is scarcely possible to present elementary notices on a simpler and more available plan. One consequence of this is, the impossibility of further analysis. Our readers must, therefore, rest contented with a reference to the work itself."—*Athenæum*, May 28th, 1842.

STEAM ENGINE, STEAM NAVIGATION, AND RAILWAYS.

Seventh Edition, with very numerous Illustrations, 8vo, 12s. cloth,

THE STEAM-ENGINE EXPLAINED and ILLUSTRATED; with an account of its Invention and progressive Improvement, and its application to Navigation and Railways: including also a Memoir of Watt. By Dr. LARDNER.

GUIDE TO THE STARS.

In 8vo, with 12 Maps, price 6s. 6d cloth,

TWELVE PLANISPHERES, forming a Guide to the Stars for every Night in the Year; with an Introduction.

COMPLETION OF MULLER'S PHYSIOLOGY.

In two volumes 8vo, each volume 20s.,

ELEMENTS OF PHYSIOLOGY. By J. MULLER, M.D., Translated from the German, with Notes, by WILLIAM BALY, M.D. With Steel Plates and very numerous Wood Engravings.

"We do, however, recommend it very strongly, and we have no hesitation in saying that it will supersede all other works as a Text Book for Lectures, and one of reference for students. It steers a middle course between the superficial brevity of many of our modern works, and the pleonastic and metaphysical jargon of Burdach."—*Med. Chir. Review*, April 1838.

Printed by WILLIAM SPOTTISWOODE, of Gate's Buildings, and FREDERICK MULLETT SPOTTISWOODE, of No. 3, Cheltenham Terrace, Gate's Buildings, both in the Parish of Middlesex, Printers, at their office in Duke-street, Lincoln's Inn Fields, in the Parish of St. Clement Danes, in the County of Middlesex; and published by the said WILLIAM SPOTTISWOODE, at No. 5, Crown and Chancery Lane, in the Parish of St. Clement Danes, in the said County, [illegible] Saturday, July 29, 1843.

THE GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE.

A Stamped Newspaper of Rural Economy and General News.—The Horticultural Part Edited by Professor Lindley.

No. 31.—1844. SATURDAY, AUGUST 3 [Price 6d.

Tremandra Hugelii, 10s 6d. to 21s.
Veronica speciosa, 4s to 15s
Erica elegans, fine and healthy, 15s, 24s, and 30s. per doz

THOMAS JACKSON, Kingston Nursery, Surrey, August 1

WOODLANDS NURSERY, Maresfield, near Uckfield, Sussex
VERBENA HUDSONII

WM. WOOD AND SON, having purchased the entire stock of the above magnificent VERBENA, beg leave to solicit attention to Dr LINDLEY's opinion of it in the *Gardeners' Chronicle*, July 6th, p 448

"W W.—Hudsonii is a good variety, bright rosy purple, with a white eye, distinct in colour" To which description W. W. & S may be allowed to add, that the flowers are large and very showy; it has been seen by several competent judges, who have pronounced it to be a variety of first-rate merit. Plants will be ready for sending out on the 20th August next, packed in tin cases and forwarded post-free, at 3s 6d each, with the usual allowance to the Trade when six plants or more are taken at once

A remittance will be expected from an known correspondents

MR. LYNE'S NEW SEEDLING GERANIUMS.

WILLIAM E. RENDLE has much pleasure in offering to the Nobility, Amateurs, and Trade the following new varieties of GERANIUMS raised by P E Lyne, Esq, the entire stock of which he has succeeded in obtaining.

Lyne's Princess Alice	. . .	each £1	1s.
Lyne's White Perfection	. . .	,, 1	1
Lyne's Imogene	. . .	,, 1	1
Lyne's King of Saxony	. . .	,, 1	1
Lyne's Redworth	. . .	,, 1	1
Lyne's Confidence	. . .	,, 1	1
Lyne's Sappho	. . .	,, 1	1

The whole set as above for six guineas The usual discount to the Trade.

"Princess Alice" has received two seedling prizes in London. "White Perfection," first prize at Torquay, and the Gold Medal at Plymouth. "Imogene" is described in the *Chronicle*, June 29th, 1843 They all possess most desirable properties, and can be highly recommended as being first rate flowers

W. E. R. has been induced to offer the above at present considerably lower than usually obtained for such valuable varieties, in hopes thereby to meet with a more extensive demand. Descriptions can be obtained on application.

Orders will be executed in strict precedence. Plants will be delivered in October next Reference or remittance required from unknown correspondents. Plants will be added to compensate for carriage.—Union Road Nursery, Plymouth, July 26

SPLENDID NEW SEEDLING CINERARIAS.

MICHAEL BREWER, Sen., begs to return his best thanks to his numerous friends who last season favoured him with their orders, and to apprise them that in addition to his own extensive List of varied Self and party-coloured new and truly splendid Seedlings of the present year, he made purchase of every new advertised and well-described kind, which having propagated and seeded to great extent, he is now prepared to execute orders for strong seedling plants, fit for furnishing to the Greenhouse, through the autumn and winter months, a varied, lively, and continuance of elegant bloom, comprising every shade of deep rich purple, dark and light blue, &c., at 9s per doz, basket, &c. included. Also seed of the same, which he confidently recommends on account of all being grown mixed together. Mixed and collected in packets, at 6d. each.

Letters, inclosing post-office orders or stamps, will be immediately attended to.—Nursery, London-road, Cambridge.

CAMELLIA.—A Seedling CAMELLIA, raised by a gentleman in the neighbourhood of Manchester, and named "Duke of Lancaster," a drawing of which may be seen at Mr. J. W. DRAPER'S, Covent Garden, London, from whom further information may be obtained; also by R. E. Yardley, Esq., Ancoats-grange, Manchester.

GREAT YARMOUTH NURSERY. NORFOLK, 1844.

NURSERYMEN AND FLORISTS TO HER MAJESTY THE QUEEN.

YOUELL AND CO.'s splendid and extensive Collection of CARNATIONS, PICOTEES, and FUCHSIAS is now in Bloom, to which they beg to invite the attention of Amateurs and others Upwards of 2000 pots of Carnations and Picotees will be staged, comprising all the leading varieties in cultivation, and embracing several new Picotees of the highest merit, raised by the Rev J. Burroughes, of Lingwood Lodge, Norfolk, to which first class Prizes have already been awarded.

Steamers from London Bridge and St Katherine's Wharf every Tuesday and Saturday evenings at 6 o'clock. Coaches from Spread Eagle, Gracechurch-street, and Eastern Counties Railway every morning and evening at 7 o'clock.

Y. and Co.'s Collection of Fuchsias continue to be forwarded per post, free, to any part of the United Kingdom, at the following prices —12 extra fine varieties, containing most of the new kinds sent out this season, for 21s; 12 fine ditto, 12s.

The Carnations and Picotees will be ready for delivery the latter part of September, at the following prices.—12 pairs extra fine and superb Show Flowers, 2l 10s; 25 ditto ditto ditto, 3l.; 12 very fine ditto, 1l 10s; 25 ditto ditto, 2l.

Great Yarmouth Nursery, August 1, 1844

J. AND J. FAIRBAIRN, beg most respectfully to acquaint their friends and the public, that they have now many very interesting specimens of HEATHS in flower, which they feel assured will be found worthy of inspection Open every day, (Sundays excepted) admission gratis —Nurseries, Clapham, near London, July 30, 1844

THUNBERGIA CHRYSOPS.

W SKIRVING, NURSERY AND SEEDSMAN, Walton, near Liverpool, begs to offer the above new and splendid Climber, surpassing in beauty all others of the genus yet introduced. It is a native of Sierra Leone; a perennial of strong and shrubby habit, and a free bloomer Colour, dazzling purple, with rich yellow eye Raised at Knowsley Hall, from seed imported by the Right Hon the Earl of Derby, and presented to W S by his lordship Plants are now ready to be sent out at 10s 6d each

Orders accompanied with a remittance or a respectable reference, will be faithfully and promptly executed —Walton Nursery, 25th July, 1844.

T AND J. BACKHOUSE, NURSERY & SEEDSMEN, York beg to offer to the notice of the Public their following fine SEEDLING PANSIES.—

YORKSHIRE ECLIPSE —"No 1 is a large flower, of good form, white ground, blue purple upper petals, and broad margin of the same round the lower petals; the petals meet well above the eye, a good flower" 3s 6d

BEAUTY OF HOLDGATE.—"No. 2 is your best flower, the eye large and intensely dark ground light buff, bedding purple, upper petals the same, a brilliant and striking flower" 3s 6d (See *Gardeners' Chronicle* p 290, for 1844)

EARL OF ZETLAND is a flower of excellent form, yellow ground, bronzy crimson upper petals, with broad bedding of the same round the lower petals, which meets well above the eye; a distinct and very constant show flower 3s 6d

Strong plants are now ready for sending out, postage free when three or more plants are taken. A remittance required from unknown correspondents

TO NOBLEMEN AND GENTLEMEN'S GARDENERS

EARLY POTATO SEED.—M. SMITH having been very successful in raising Early Potatoes from the seed of the Potato Plum, is happy in being able to offer Potatoes for seed of so early and fine a quality as has not been equalled. The first is his six weeks Dwarf Seedling This is a very fine early Potato, so early that with ordinary cultivation it will be ready for use in six weeks from the time of planting It is particularly well adapted for forcing, being so dwarfish in the stem as not to exceed from four to six inches in height The Potato is very shallow eyed, and of first rate quality, but not large, the largest being about the size of a bantam's egg.—Price 20s the imperial pound

Second, his prize taking Seedling This is a very early, large, and fine Potato, shallow eyed. It has taken the first prize at the Berwickshire Horticultural Shows during the last two years for its size, beauty, and good quality —Price 15s the imperial stone.

Third, his second Early Seedling This is a Potato of first rate quality, comes in class after the Prize taker, is a rich bearer and shallow-eyed, making up the blank between the first Early and what is commonly termed American or Second Early —Price 15s the imperial stone.

Those wishing to be supplied with seed of any of the above Seedling Potatoes will address their order to Mr Smith, Gardener, Ayton, Berwickshire, with a Post-office order for the amount of their demand They are requested to give their address distinctly, that the Potatoes may be forwarded without delay to the proper quarter Early application will be necessary to obtain a supply, as the stock is limited.

All orders will be punctually attended to, and the Potatoes forwarded, packed in boxes, with moss or hay, to protect them from injury by carriage. Ayton, July 15, 1844 M. SMITH

THE WALCHEREN CAULIFLOWER.

MESSRS. MARNOCK AND MANLEY beg to inform their friends and the public that they have a few packets of the above genuine article left, which should be sown for a general crop to stand the winter from the 15th to the 20th of August. Owing to the excessive dry season, the spring sowing has not turned out so favourable as it otherwise would have done, but they will warrant it to answer every description given of it in their treatise —Nursery, Hackney, July 31, 1844.

SHILLING'S QUEEN CABBAGE.—This month and part of August being the time to sow Cabbage Seed for the Autumn and Spring Planting, J. & S. SHILLING having a little seed left of the above very superior kind, which they highly recommend to those who have not already tried it, beg to offer it to the Public generally, in half oz. packets, postage free, at 1s. 6d. each, on the receipt of postage stamps or a Post office order.—Knowle Nursery, Knowle, Farnham, Hants.

Post Agent for London, Mr. Kennan, 4, Great Russell-street, Covent Garden.

JESSOP'S NURSERY, Cheltenham, Established 1815, from its extensive connection, offers peculiar advantages to Noblemen and Gentlemen requiring Gardeners, Foresters, or Farm bailiffs, of established skill and respectability. All communications promptly attended to.

THE HAMPSHIRE BROWN COS LETTUCE.

The middle to the end of August being the time for sowing Lettuce seed to stand the winter, J. and S. SHILLING invite the attention of the Public generally to the above, which they can with confidence recommend as superior to any other kind for winter and summer use It is quite hardy, and will not run to seed They have sent a few heads to Mr. Kernan's, No. 4, Great Russell street, Covent Garden, where it may be seen. ½ oz packets at 2s 6d each, free, on the receipt of postage stamps or a Post-office order.

P S —Mr Kernan is Agent for this as well as their Queen Cabbage —Northwarnboro' Nurseries, Odiham, Hants, Aug. 1.

BENIALL'S IMPROVED PAPER FOR DRYING PLANTS.

W AND T. BENTALL earnestly invite the attention of Botanists to the above Paper; its perfect adaptation to the purpose for which it is prepared having been fully proved The following valuable testimonial has been kindly received —

"I highly approve of your new Paper for drying plants, and consider it far preferable to the Cambridge Chalk Paper, which I previously employed, but which will now be entirely discarded by me in the preparation of plants for the herbarium. I have also found it most valuable in drying Algæ, the most decisive test in my opinion, to which such papers can be subjected; and can safely recommend it to all engaged in the study of these plants"—*Rev. W. H. Harv, M.A. F.L.S., &c., Plinlimmon, Devonport*

Professor LINDLEY, C. C. BABINGTON, Esq, M.A. F.L.S. &c., H C WATSON, Esq, F.L.S &c, have also kindly allowed the use of their names as strongly recommending it. To be had of the Manufacturers, Halstead, Essex, and of their Agents, Mr. E NEWMAN, 9, Devonshire-street, Bishopsgate, London; and Mr R S MELNTOSH, 12, Catherine-street, Edinburgh.

Sizes, 16 by 10 inches (when folded), 14s. per ream; 20 by 10 inches, 20s do; 16 by 20 inches, 25s do.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and despatch.—This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by men or women It is easily set, so as to deliver the exact quantity of Seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Mangold Wurzel Seed, Wheat, Barley, Peas, and all kind of Garden Seeds. 1l 10s each. Commission allowed to Agents.

These Dibbles may be obtained through the agency of the principal Agricultural Implement Sellers, in the United Kingdom; or from the Inventor, by letter, to his address, inclosing a Post-office order for the amount RICHARD SMITH, Upper Hall, near Droitwich, Worcestershire.

LYNDON'S PATENT SPADE.—Sold by GREEN and CONSTABLE, Ironmongers, 36, King William st., London-bridge Horticultural Tool Chests, Bright Ladies' Spades, Money's Patent Water Pots, Lord Vernon's Patent Hoes, with a general assortment of Garden Implements.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	Orange Tubs, Flower Boxes, &c.
Garden Edging	

EDWARD BECK will be happy to answer any inquiries, either personally or by post.

TO HORTICULTURAL BUILDERS.

A GENTLEMAN wishes for a PLAN and ESTIMATE for a small GREENHOUSE or CONSERVATORY, to be erected at the end of his Drawing room (which end faces the west, and the front the south, and from which a door of communication opens), size 15 feet 6 inches by 12 feet; there is a return wall of 5 feet to be glazed with Drabble's Sheet Glass, and finished in the best manner.—Direct to E. L., at the Office of this Paper

HOTHOUSES, CONSERVATORIES, &c.,' made and fixed Complete in all parts of the Kingdom One, two, and three-light Cucumber and Melon Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom, warranted best material Two light Boxes and Lights complete, from 14s. 6d. Garden Lights made and glazed from 1s. per foot, at JAS. WHITE' Sash Manufactory, Chelsea-place, Old Kent-road. *** References given.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—ANNUAL COUNTRY MEETING of 1845, to be held at SHREWSBURY, in the North Wales District, comprising the Counties of Anglesey, Carnarvon, Merioneth, Montgomery, Denbigh, Flint, Chester, Salop, and Stafford. The Prizes are open to general competition. Forms of Certificate to be procured on application to the Secretary, 12, Hanover-square, London. All Certificates for Implements must be returned, filled up, to the Secretary, on or before the 1st of May, and all other Certificates by the 1st of June; the Council having decided that in no case whatever shall any Certificate be received after those dates respectively.

PRIZES FOR IMPROVING THE BREED OF CATTLE.—1845.

Short-horns.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 30*l.*; to the owner of the second best do. do., 15*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 20*l.*—3. To the owner of the best Cow in milk or in calf, 15*l.* (In case of the Cow being in calf, and not in milk, the Prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in-calf Heifer, not exceeding three years old, 15*l.*—5. To the owner of the best Yearling Heifer, 10*l.*—6. To the owner of the best Bull-calf, not exceeding one year old, 10*l.*

Herefords.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 30*l.*; to the owner of the second best do. do., 15*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 20*l.*—3. To the owner of the best Cow in milk or in calf, 15*l.* (In the case of the cow being in calf, and not in milk, the Prize will not be given until she is certified to have produced a calf.) 4. To the owner of the best in-calf Heifer, not exceeding three years old, 15*l.*—5. To the owner of the best Yearling Heifer, 10*l.*—6. To the owner of the best Bull-calf, not exceeding one year old, 10*l.*

Devons.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 30*l.*; to the owner of the second best do. do., 15*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 20*l.*—3. To the owner of the best Cow in milk or in calf, 15*l.* (In the case of the Cow being in calf, and not in milk, the Prize will not be given until she is certified to have produced a calf.) —4. To the owner of the best in-calf Heifer, not exceeding three years old, 15*l.*—5. To the owner of the best Yearling Heifer, 10*l.*—6. To the owner of the best Bull-calf, not exceeding one year old, 10*l.*

Cattle of any Breed (not qualified to compete in the foregoing classes).—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 20*l.*; to the owner of the second best ditto, 10*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 15*l.* —3. To the owner of the best Cow in Milk or in calf, 15*l.* (In the case of the cow being in calf, and not in milk, the prize will not be given until she is certified to have produced a calf.) —4. To the owner of the best in-calf Heifer, not exceeding three years old, 10*l.*—5 To the owner of the best Yearling Heifer, 10*l.*

HORSES.

CLASS 1. To the owner of the best Stallion for Agricultural Purposes, of any age, 30*l.*; to the owner of the second-best do. do., 15*l.*—2. To the owner of the best three years old do., 15*l.*—3. To the owner of the best two years old do., 15*l.*—4. To the owner of the best Mare and Foal for Agricultural Purposes, 20*l.*; to the owner of the second-best do., 10*l.*—5. To the owner of the best two years old Filly, 10*l.*—6. To the owner of the best Thorough-bred Stallion, which shall have served mares at a price not exceeding 3 guineas (and with a groom's fee of not more than 5*s.*) in the season of 1845, 30*l.*

SHEEP.

PRIZES FOR IMPROVING THE BREED OF SHEEP.—1845.

Leicesters.—CLASS 1. To the owner of the best Shearling Ram, 30*l.*; to the owner of the second best do., 15*l.*—2. To the owner of the best Ram of any other age, 30*l.*; to the owner of the second-best do., 15*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do. do., 5*l.*

South-down Sheep.—CLASS 1. To the owner of the best Shearling Ram, 30*l.*; to the owner of the second best do., 15*l.* 2. To the owner of the best Ram of any other age, 30*l.*; to the owner of the second-best do., 15*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do. do., 5*l.*

Long-Woolled Sheep. (Not qualified to compete as Leicesters.) —CLASS 1. To the owner of the best Shearling Ram, 30*l.*; to the owner of the second-best do., 15*l.*—2. To the owner of the best Ram of any other age, 30*l.*; to the owner of the second-best do., 15*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do. do., 5*l.*

Sheep best adapted to a Mountain District.—CLASS 1. To the owner of the best Ram of any age, 15*l.*; to the owner of the second-best do., 10*l.*; to the owner of the third-best do., 5*l.*—2. To the owner of the best pen of Ewes of any age, 10*l.*; to the owner of the second best do., 5*l.*

PIGS.

CLASS 1. To the owner of the best Boar of a large breed, 10*l.*; to the owner of the second-best do. do., 5*l.*—2. To the owner of the best Boar of a small breed, 10*l.*; to the owner of the second best do. do., 5*l.*—3. To the owner of the best breeding Sow, of a large breed, 10*l.*—4. To the owner of the best breeding Sow, of a small breed, 10*l.*—5. To the owner of the best pen of three breeding Sow-pigs, of the same litter, above four and under ten months old, 10*l.*

AGRICULTURAL IMPLEMENTS.

A sum not exceeding 300*l.*

Cheese.—To the exhibitor of the best two Cheese (of any kind) made within the district, 10*l.* To the exhibitor of the second-best do., 5*l.*

Extra Stock, Roots, and Seeds.—For Extra Stock, of any kind, not shown for any of the above Prizes, and for Roots, Seeds, &c., Prizes may be awarded and apportioned, by the Committee and Judges, to an amount not exceeding in the whole 50*l.*

Any New Implement.—For the invention of any new Agricultural Implement, such sum as the Council may think proper to award.

Seed Wheat, Barley, and Oats.—I. Fifteen Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of white Wheat, of the harvest of 1844, and grown by himself.

II. Fifteen Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of red Wheat, of the harvest of 1844, and grown by himself.

III. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of spring Wheat, of the harvest of 1844, and grown by himself.

IV. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of Barley or malting, of the harvest of 1844, and grown by himself.

V. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of Oats, of the harvest of 1844, and grown by himself.

Competitors are requested to send with their Wheat, Barley, or Oats, specimens, fairly taken, of the same in the car, with the whole of the Straw, in a sheaf not less than one foot in diameter, and with the roots attached.

Two bushels of the Wheat, Barley, or Oats, will be sealed up by the Director or Stewards, and one of the remaining bushels of each variety will be exhibited as a sample to the public; the other being kept for comparison with the produce of the next year. At the General Meeting in December, 1846, the Prizes will be awarded.]

The two best samples of each of these classes of Wheat, Barley, or Oats, without at that time distinguishing, in any of the cases, between the comparative merits of either sample, will be selected by the Judges appointed for the Meeting at Shrewsbury; and will be sown, under the direction of the Council (the winter Wheats in the autumn of 1845, and the spring Wheat not earlier than the 1st of March, 1846), by four farmers, who will make their report, upon which the Prizes will be awarded, provided there be sufficient merit in any of the samples. 10*l.* will be given at the Meeting at Shrewsbury to each exhibitor whose Wheat has been selected for trial, and 6*l.* for the Barley or Oats.

*** No variety which has been selected for trial at any previous Show shall be qualified to compete in the same class.

ESSAYS AND REPORTS ON VARIOUS SUBJECTS.

Prizes for 1845.—PRIZE ESSAYS.

1. *Farming of Nottinghamshire.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Nottingham. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Nottinghamshire since the Report of Mr. Robert Lowe in the year 1798; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

2. *Farming of Cornwall.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Cornwall. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Cornwall since the Report of Mr. G. B. Worgan, in the year 1811; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

3. *Farming of Kent.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Kent. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Kent since the Report of Mr. John Boys, in 1805; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

4. *Heath Land.*—Twenty sovereigns, or a piece of plate of that value, will be given for an account of the best method of reclaiming heath-land. Competitors will be required to describe methods which have been successfully adopted in the reclaiming of heath-land, reference being had especially to the following points:—1. The mode of breaking up, whether by paring and burning, or by simple ploughing. 2. The application of lime. 3. The course of cropping. 4. The conversion of heath-land into pasture, where either the steepness of the land, or its elevation above the sea, does not allow the culture of corn.

5. *One Horse Carts.*—Ten Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on the advantages of One-horse Carts. Competitors will be required to point out the saving in horse-labour, and other advantages which undoubtedly arise from the substitution of one-horse carts for waggons.

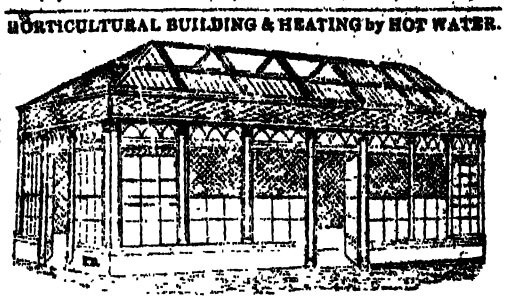
6. *Catch-Meadows.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on Catch-Meadows. Competitors will be required to describe the best and cheapest method of forming water-meadows on the sides of natural slopes, as practised in Somersetshire and Devonshire; the mode of managing them, and of applying their produce, the increase of value thereby given to unproductive hill-sides, and to state how far this mode of improvement might be applied to the mountainous districts of Wales and of the North of England.

7. *Fences.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on Fences. Competitors will be required to describe the best and neatest methods of maintaining hedges, whether for arable or for grazing ground; and to point out how far the present fences in various parts of England are injurious to the farmer, whether by their size, their excess in number, or the over-abundance of timber which they contain.

8. *Fattening Cattle.*—Ten Sovereigns, or a Piece of Plate of that value, will be given for an account of the best method of fattening cattle; as to the places in which they are kept, large or small yards or stalls; as well as the food, roots, hay, &c. on which they are fed during the time of fattening.

9. *Tile yards.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the cheapest and best method of establishing a Tile yard. Competitors will be required to attend to the following points:—1. Mode of working the clay, according to its quality. 2. Machine for making the tiles. 3. Sheds for drying the tiles. 4. Construction of the kiln. 5. Cost of forming the establishment. 6. Cost of the tiles when ready for sale.

10. *Curing Butter.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best description of the Dutch method of salting butter; pointing out the causes of its superiority to other salted butters



11. *Experiment in Agriculture.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for an account of the best Experiment in Agriculture.

These Essays must be sent to the Secretary, at 12, Hanover-square, London, on or before March 1st, 1845.

Rules of Competition for Prize Essays.—1. All information contained in Prize Essays shall be founded on experience or observation, and not on simple reference to books, or other sources. 2. Drawings, specimens, or models drawn or constructed to a stated scale, shall accompany writings requiring them. 3. All competitors shall enclose their names and addresses in a cover, on which only their motto, and the subject of their Essay, and the number of that subject in the Prize list of the Society, shall be written. 4. The President or Chairman of the Council for the time being, shall open the cover on which the motto designating the Essay to which the Prize has been awarded is written, and shall declare the name of the author. 5. The Chairman of the Journal Committee shall alone be empowered to open the motto paper of such Essays, not obtaining the Prize, as he may think likely to be useful for the Society's objects, with a view of consulting the writer confidentially as to his willingness to place such paper at the disposal of the Journal Committee. 6. The copyright of all Essays gaining prizes, shall belong to the Society, who shall accordingly have the power to publish the whole or any part of such Essays; and the other Essays will be returned on the application of the writers; but the Society do not make themselves responsible for their loss. 7. The Society are not bound to award a prize unless they consider one of the Essays deserving of it. 8. In all reports of experiments the expenses shall be accurately detailed. 9. The imperial weights and measures only are those by which calculations are to be made. 10. No prize shall be given for any Essay which has been already in print. 11. Prizes may be taken in money or plate, at the option of the successful candidate. 12. All Essays must be addressed to the Secretary, at the house of the Society.

(By Order of the Council) JAMES HUDSON, Secretary.

HORTICULTURAL BUILDING & HEATING by HOT WATER.

J. WEEKS and Co., ARCHITECTS, &c., Gloucester-place, King's-road, Chelsea, Hothouse-Builders, and Hot-water Apparatus Manufacturers, beg leave to inform the Nobility and Gentry, that their business, which has been extensive throughout the country for many years, is entirely confined to the BUILDING OF HORTICULTURAL ERECTIONS of every description, and the HEATING of them by HOT WATER.

CONICAL and other BOILERS of all sizes; their largest consumes but a small quantity of fuel, only requiring attention once in 10 hours, and will heat a range of Forcing-houses 300 feet in length.]

Their improved plan of BOTTOM-HEAT FOR PITS, by means of an open trough under the bed, is now being universally adopted.

References may be had, and their works seen at most of the Nobility and Gentlemen's seats in the country, nearly the whole of the London Nurseries, and a great variety of Horticultural Erections and Hot-water Apparatus, Models, Plans, Estimates, &c., at their Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane-square.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

TURNIP SEASON.

GUANO (Foreign and Potter's), RAPE-DUST, BONE-DUST, CLARKE'S COMPOST, and all other MANURES for the TURNIP CROP, to be had on the best terms, of MARK FOTHERGILL, 46, Upper Thames-street.

RARE ORCHIDACEÆ FROM THE EAST INDIES.

MESSRS. J. C. AND S. STEVENS, beg to announce they will sell by Auction, at their Great Room, 38, King-st., Covent Garden, on Thursday 15th August, at 1 o'clock, a Case of Terrestrial and Aerial Orchidaceæ, which have just arrived in fine health, and gathered during the months of January and February last, on the Steeps of the Ghaus, in the Presidency of Bombay. On view two days prior to the Sale; and Catalogues had of the Auctioneers, 38, King-street, Covent Garden.

BEDFORDSHIRE.—Very Eligible Freehold Estates in the parish of Sandy, cultivated as Garden Ground, and offering to Trustees safe and profitable Landed Investments, not to be influenced by any change in the Corn laws. Also a Freehold Family Residence, and other property, at Caldecote. The whole Tithe free and Land Tax redeemed.

MESSRS. BUSHWORTH AND JARVIS are instructed by the Mortgagees, with the concurrence of the Devisees in Trust under the will, to sell by Auction, at Garraway's, London, on Friday, Aug. 23d, at 12 o'clock, in 15 Lots, (unless previously disposed of by private contract), a very desirable Freehold Property, comprising 170 acres of land, with two Farm Homesteads; situate at Beeston, in the parish of Sandy; a district proverbial for the remarkable richness and fertility of the soil, and highly valuable as garden ground; a portion of which was late in the occupation of the deceased, and the remainder is let on long leases to responsible tenants, at almost incredibly high rents; and substantial additional advantages to the property may be looked for from the newly-projected Line of Railway, direct from London to York, which is contemplated will pass over this estate. There are likewise several Cottages, a Wheelwright's shop, and Beer-house, at Beeston Green. Also a spacious Family Residence, with possession, in a fine sporting country, and having extensive stabling and out-buildings, a Licensed Ale-house, eleven Cottages near thereto, and 4 acres of luxuriant garden ground adjoining, situate at Caldecote, only one and a-half mile distant from the preceding property, and equidistant with the capital Market Town of Bedford, and only 47 miles from London on the great north road.—Printed particulars, with plans, may be obtained on the premises at Caldecote, at the principal Inns in the neighbouring towns, and in London, of Messrs. Barker, Rose, and Norton, Solicitors, 30, Mark-lane; Messrs. Gregory, Faulkner, Gregory and Bourdillon, Solicitors, 1, Bedford row; at Garraway's; and at the Offices of Messrs. Bushworth and Jarvis, Land Surveyors and Auctioneers, Saville-row, Regent-street, and 19, Change Alley, Cornhill.

SOUTHAMPTON.—SMALL CONSERVATORY FOR SALE TO BE SOLD, a most complete and modern Green-house, with span roof and bow front; 18 feet by 12 feet, with two stages, furnace, &c., and with or without a choice Collection of Plants; the whole the property of a Lady, who is removing.—For particulars apply to WITHAM and ROSSARS, Auctioneers, &c., Above Bar, Southampton.

FARMS TO LET.—240 ACRES.

TO LET ON LEASE, a FARM in the County of Wilts, near B——th, of 110 acres—40 Meadow and 70 Arable—in a high state of cultivation, and Crops; with most complete and extensive Farm Buildings, adapted for profitable Scientific Farming, which may be entered upon immediately, and crops taken at a valuation, or at Michaelmas. In addition to which, another FARM adjoining, of 130 acres, principally Arable, will be added, on the lease expiring next year. Well situated for great Markets, and Turnpike-roads and Canals running through or close by them. The Tenant must prove his having a sufficient capital. Direct to Mr. EVANS, Estate Agent, &c., 46, Milsom-st., Bath, or (Thursdays) No. 2, Bridge-st., Bristol.

NEW AND RARE PLANTS.

W. J. EPPS begs respectfully to offer the following new and valuable Plants:—

Achimenes picta, 10s. 6d. to 15s.
" hirsuta (strong plants), 2s. 6d.
Buddlea Lindleyana, 10s. 6d., strong stocky plants, 21s. 6d. (new and splendid variety, from China, flowers of a beautiful blue)
Thunbergia chrysops
Drymonia punctata, 10s. 6d. (for description see Paxton's Magazine for June)
Habrothamnus fasciculatis, 5s.
Bruguiannia parviflora, 5s.
" Knightii, 5s.
Pentas carnea, 5s.
Clerodendron laxifolium, 7s. 6d.
Gloxinia Cartonii, 10s. 6d.
" bicolor, 7s. 6d.
" magnifiora, 7s. 6d.
" insignis, 7s. 6d. (these are the finest varieties known)
Begonia coccinea, 7s. 6d.
Rose, Cloth of Gold, 7s. 6d.
Fuchsia, Kentish Bride, blue corolla, pink tube and sepals, decidedly the finest variety sent out this year, strong plants, 2s. 6d.

Orders to be accompanied with a remittance or a respectable reference.—Bower Nursery, Maidstone, Aug. 1, 1844.

The Gardeners' Chronicle.

SATURDAY, AUGUST 3, 1844.

MEETING FOR THE FOLLOWING WEEK.

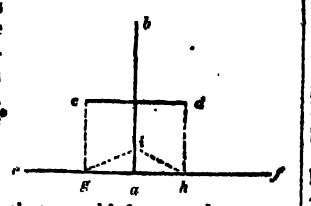
Tuesday, Aug. 6 Horticultural . . . . 8 p.m.

COUNTRY SHOW.

Tuesday, Aug. 6 . . Coppice Carnation and Picotee Show.

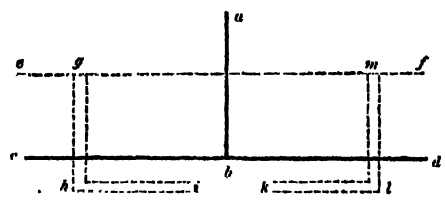
As Musical Promenades are not matters of horticultural interest, even although they are held in a garden, we think it unnecessary to say much of that which the noble President and the Council of the Horticultural Society so liberally provided last Wednesday for the disappointed holders of Exhibition tickets. It is sufficient to state that the effect of the admirable music was quite delightful—that the scene was very gay, the visitors highly gratified, and the meeting in all respects a very pleasant one, notwithstanding a shower or two and threatening clouds. The number present was 2267.

"I have a fine Mulberry-tree," says an inquirer, "upwards of 200 years old, and perhaps 18 feet high, of which I am extremely proud; but on account of some alterations I am going to make in my grounds this autumn, its roots will be buried 5 or 6 feet below the surface, if the tree is allowed to remain as it is; and I wish to know what is best to be done under the circumstances—whether to allow the roots to be so buried, or, if I shall be obliged to raise them, how, and at what time it will be best to do so." As this is a question the answer to which will doubtless interest other persons besides our correspondent, it seems to deserve a more prominent place than is usually given to such communications.



We know, from experience, that many people, otherwise well-informed, believe that roots may be buried to any depth without injury, and are surprised to find, when they act upon that belief, that their plants either perish or grow sickly. Do not we see, say they, that the roots of trees descend of themselves to great depths below the surface; and if so, why should we not also bury them to such depths? And it must be admitted, that if the premises in this case were true, the inference would be true also. But, with great deference to popular opinion, we are obliged to say, that roots never reach far below the surface of the soil, and when they do, it is owing to particular circumstances. Some years since, an acquaintance produced a Lucerne-root, 18 feet long, in proof of the common belief: but a little investigation showed that root to have been formed in the side of a gravel-pit, along the steep face of which it had pursued its course, without ever being above 6 inches from the surface.

The truth is, that roots must have access to atmospheric air, for chemical reasons into which we shall not enter just now; and the exclusion of it from roots, which necessarily happens when large masses of earth are heaped upon them, is as fatal as suffocation would be to ourselves. Under natural circumstances the tendency of the roots to keep near the surface is invincible; and this should of itself teach us how important to them is free access to air.



"The celebrated Duhamel," says Col. Greenwood, "wishing to protect his field from robbery from the roots of a row of Elms, cut a deep ditch between the Elms and his field. The roots, however, were not to be done. They of course followed the surface of the ground, whether down, horizontal, or up hill, and took the ditch 'in and out clever' into the philosopher's field. Duhamel thinks these were very cunning roots, and that they had an instinctive notion of the treat they were to have on the other side of the ditch, and grew *at* it. Had the philosopher built a wall in the ditch, and then filled it in, he would have beaten the roots, on account of their inability to leave the surface and get under the wall."

Nothing can be more just than this observation, and it puts in the truest light the question as to whether roots may be buried or not.

Nevertheless, although roots cannot be buried to any considerable depth without danger, yet it is possible to pile masses of earth round trees with impunity. The absorbing parts of a tree's root are its extremities, and provided they are in free communication with air, it matters little what becomes of the other part. Let us suppose that the figure *a b c d* represents a tree, of which *a b* is the height, and *c d* the spread of the branches. Then the spread of the roots would probably be equal to *e f* (a point that would have to be ascertained by examination), and if so, there would be no disadvantage in heaping up soil as high as *i*, over *g a* and *a h*, because *e g* and *h f*, where the extremities of the roots are found, would still be as freely exposed to air as before the operation.

Nor is it clear to us that earth might not be heaped over the roots of a tree to any required depth, provided air-passages were left among the roots. Let

us suppose, for instance, that *a b* represents the stem of a tree, and *c d* the spread of its roots, while *e f* shows the mass of earth placed over them. It is probable that if the shafts *g h* and *m l* were connected with the drains *h i* and *k l*, and there were several of them round the tree—say 6 or 8—it is probable that under those circumstances the tree would not suffer much or long; it would, however, be an experiment for the success of which we would not answer.

As to removing a Mulberry-tree 18 feet high and 200 years old, it is not to be thought of without considerable mutilation. If it is absolutely necessary to transplant the tree, the course which we should follow would be this:—We should get up its roots, to the extremities of the fibres, with what care we could; we should then cut off all the young wood, so as to render impossible any sudden drain upon the roots when the season for leafing returns; and we should, when transplanting it, throw a quantity of superphosphate of lime into the hole where the young roots are, so that they might be in contact with it. We should perform the operation as soon as the leaves had fallen, which would be after the first frost; and then, securing the trunk firmly in its place, we should leave the rest to Nature, with reasonable confidence in the success of the experiment.

It is not very long since an ingenious person undertook to prove, from historical evidence, that no such person as Napoleon Bonaparte ever existed. A writer in the *Hereford Times* is determined to rival the historical critic, for he asserts that the Potato was not originally brought to Europe from America, as we are simple enough to believe. On the contrary, "It would seem to be probable that the Potato was known as much as three hundred years before the Christian era, having been accurately described as the *αραχιδνα*." What a pity it is that gentlemen will not write about what they understand! A very little inquiry would have informed the correspondent of the *Hereford Times* that this Arachidna of Theophrastus was a Lathyrus, and in all probability either *L. tuberosus* or *L. amphicarpos*.

NOTES ON THE CONIFERÆ OF JAPAN.

So much interest is now taken in forming Pineta and in collecting Coniferous plants, that I have thought the following remarks on the kinds found in Japan, and lately described by Drs. Siebold and Zuccarini in the "Flora Japonica," may be of use to those interested in such matters, and also in directing those who may at some future time have an opportunity of visiting Japan, and procuring either plants or seeds of those kinds which yet remain to be introduced into England; and this is more particularly desirable, on account of their being quite hardy.

Abies leptolepis of Siebold. "Flora Jap.," Tab. 105, p. 12.—This is a very distinct dwarf kind of Larch, and is the same as Larix sibirica of Drs. Ledebour and Bunge, but is a very distinct species from that found in most English and foreign collections under that name. It is very dwarf, probably never growing more than 3 or 4 feet high; and forms a dense bush, with the leaves and cones as small as those of the American Larch. Dr. Bunge was the first who sent seeds to the Horticultural Society in a living state. The Siberian Larch described by Mr. Loudon in his last edition of the "Arboretum Britannicum," p. 1051, is a very distinct kind from that of Dr. Bunge, and is, as is there stated, only the Russian variety of the common Larch, with the branches more robust, but much less numerous. It is to be found in most collections under either of the following names—Larix sibirica, L. archangelica, or L. Rossica. The Abies sibirica of Dr. Fischer is a very different species from either of the above, and is the same as Abies pichta of the "Arboretum Britannicum," and belongs to the Silver Fir section. The authors of the "Flora Japonica," in describing this curious little plant, which always comes true from seed, should have adopted the name of Larix for that of Abies, as is now generally done; then, as Dr. Bunge's name (L. sibirica) had been previously applied to the Russian Larch, the present plant would stand as Larix leptolepis.

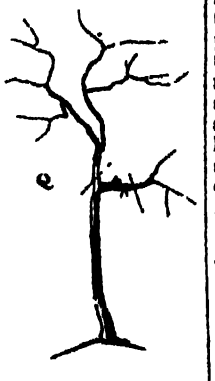
Abies tsuga of Siebold. "Flora Jap.," Tab. 106, p. 14.—This is the same as Abies dumosa of Lambert, Abies Brunoniana, Lindl., and Abies subdecidua, Wallich; and noticed by me in a former article in the *Chronicle*. It belongs to the same section as the Hemlock Spruce, which it very much resembles, and, like that species, only forms a large bush, or small tree, from 20 to 30 feet high. It still remains to be introduced, and would prove, no doubt, quite hardy.

Abies firma of Siebold. "Flora Jap." Tab. 107, p. 15.—This belongs to the Picea, or Silver Fir section, and greatly resembles in foliage and habit Abies pichta (Abies sibirica of Ledebour), but differs very much in the cones; the cones of Abies firma having the bracts considerably longer than the scales, while those of A. pichta are not so long as the scales; in fact, the cones more resemble those of the Picea pectinata, or P. cephalonica, than any other, but are not near so large. In the drawing given in the "Flora Japonica" the cones are represented as pendulous, but that is evidently a mistake. It is said to be a tall tree, and, no doubt, quite hardy; and probably only a northern form of the Picea pectinata, which still remains to be introduced.

Abies homolepis. "Flora Jap." Tab. 108, p. 17.—This very much resembles Abies Smithiana, of Dr. Wallich, both in cones and branches, and most probably is identical. The scales figured quite agree with those of Dr. Wallich's A. Smithiana, in the uneven margin and smaller size. This is very different from Dr. Royle's A. morinda, or Khutrow, a much taller and more robust tree. It is said to be a tree from 20 to 30 feet high, and belongs to the Spruce section; it remains to be introduced.

Abies bifida of Siebold. "Flora Jap." Tab. 109, p. 18.—This is the same as Picea Webbiana of the "Arboretum Britannicum," p. 1051, and is the P. spectabilis of Lambert, and Chilrow of the natives in the Himalayas. It belongs to the Silver Fir section, and is one of the most ornamental of the whole race of Pines, having beautiful large purple cones and silvery leaves. It forms a large tree in the Alps of Gossamthan, from 80 to 100 feet high, and is easily distinguished from all others yet known (except P. pindrow, of Royle), by its bifid leaves, and from that species in its much broader and shorter foliage. It is quite hardy, but is much injured in spring by late frosts.—*George Gordon.*

THE ROSE-GARDEN.—No. XV.



(Continued from p. 460.)

Pruning for Transplanting.—Having gone through all the detail necessary to secure the budded trees, and bring them into bearing, (observing that they are not on any account to be mangled, shortened, or the passage of the sap in any way obstructed during growth,) we now come to the time when the tree, having become ornamental, is fit to repay the labour laid out upon it, and to be planted out where its beauty may be seen. This is about the commencement of November, when the branches should all be cut down to about a foot long, and any leaves still left, cut off carefully midstalk, with a pair of scissors. Worked standards, carelessly treated, frequently do well the first season after transplantation; and then, dwindling away for a season or two, eventually die off.

Except where unavoidable, (as in the instance of the wild stock,) a tree should not be lopped root and branch at the same time; the double mutilation is injurious to it. Thus, half of each branch is continued, to keep up an intercourse with the root, and, when an action is established, cutting in the head is desirable. On removing trees, the fresh roots they have made, and the appearance of those which were left, will require attention in the application of the knife; in pruning a large root it should be cut to a lateral—in shortening a small to a fibre; where a plant has been examined and trimmed so recently, however, the knife should be sparingly used. And it may here be well to observe, that all cuts to remove branches, knots, or roots, should be quite clean, slanting (and deep enough to the stem, viz. even with it), and nothing left projecting, lest dead wood be the consequence, and the plant be eventually injured; all wounds should be carefully healed, and dead wood should, in all cases, be removed, and living bark encircle that which remains. The removal of the extraneous parts of the wild branch, and the stem left above it (if any), as subsequently directed, are best effected 18 months after budding, in March; if sooner, the bud is apt to be injured, as well as the wound left uncovered; but at this time they may be cut down to the base of bud and branch, and the mixture will secure the wound from injury. All summer and spring-made wounds, if clean cut, will partly cicatrize over the same year, and, if defended while in progress, will not do any future injury.

Replanting with a Dormant Bud.—In case of necessity a stock with a dormant bud upon it, of the summer's insertion, may be transplanted; but this is not desirable, although, if the wild branches to be cut off are large, it may be safely enough done, because a tree in its natural state, if the root and branches are in proportion to each other, has strength enough to carry its nourishment through the old wood, and then to make new. Old wood does not remain *in statu quo*, but is enlarged by a fresh

layer each year between the bark and wood, to enable it to bear the additional weight it has to support, as well as to enlarge the channels for the conveyance of sap to an increased head. Both these causes act upon trees which have their own natural weight to support, and therefore they are admirably adapted; only the last applies to evergreen and shrubbery, and therefore they can but barely be called so, being nearly of a size all the way up. On this showing, therefore, if the old wood be cut away, the injury done to the root in moving, is made up by the non-necessity of keeping up the old wood; and thus great part of the labour of the sap being saved, and its duty diminished, as well as a free course given to it, the buds succeed. This, it is apprehended, is the theory upon which all pruning for transplantation is founded. But, to explain this more fully:—Amongst trees, there are some of which the bark is so strong that the sap is confined in its ascent, and the tree becoming hidebound, is unable to increase, unless a slit be made from the top of the tree to the bottom; in order to give the sap full liberty to ascend. Those whose barks have become hardened and dry, may sometimes be seen to throw out buds all the way up the body of the branch, each bud being weaker than the lower one, the point of the branch dying away. This tendency of the sap to desert its former channels, may be observed in newly-planted thorns, particularly whenever they have not been cut back enough. Now, a transplanted tree frequently makes but little wood the first year, and consequently few leaves; and the intercourse between the roots and stem being thus, as it were, partially suspended, the bark becomes hard, and the next year the sap has a great difficulty in ascending. Where a check occurs in vegetation, a sufficient quantity of sap to start the leaves creeps up and accumulates by gradual steps; but when the warm weather comes on, and the shoots are expected to flourish, they are found to have no support from the root, and they go off accordingly. Shoots called Gourmands, on the contrary, and suckers, being soft and free, arrive to an astonishing size: witness the shoot of a Vine, which is frequently larger in the girt than the stem it proceeds from. A tree lately moved and planted with more branches than its roots can nourish, may be considered like a man in debt; the little it can do is absorbed by the demands upon it, and it is just able to keep up what it has. The next year sees it in the same state of weakness, with a hard bark, and the whole substance confined; it has a more difficult duty and unincreased means. Or if it has not sap sufficient to keep up its present head, its parts die off as the supply diminishes, and the tree grows weaker and weaker; and having exhausted all its supply, without an efficient return from the leaves, which are unhealthy, it dies off and perishes by degrees. On the contrary, a tree newly planted may be likened to a person who is promised that no demand shall be made upon him until he is enabled to answer it, when it is placed in the ground with no open buds upon it, and only enough closed ones to carry on the duty required when they are forced open, which will be sooner or later, according to the individual strength of the tree. The sap accumulates, the buds start at their proper time, and when started, the tree, weakened by its removal, has no length of half-dried wood to force the sap through, but the new buds throw out soft and large bases, the sap courses through them establish a give-and-take intercourse with the root at once; they require no more of the root than it can perform, and they are ready to repay with interest; and as a free passage for the fluids is as much the cause of health and vigour in the vegetable as the animal creation, the tree flourishes and succeeds. Thus, time to recover, and liberty in its work, are two great desiderata in removing a tree, and if these are attended to, a newly-budded stock may be removed, even from a hedge, with barely any root, into good ground, with perfect success, by the circumstance of the bud being placed as in this instance it would be, below the head, when the sap would have only half its original height to ascend; and as the weight of a hundred cubic feet of water would cause a fountain placed below it to rise to a certain height, and the same fountain, with only fifty feet of water above it, would play equally well, if it were only required to rise to a height proportioned to the decrease of force acting upon it: so a tree budded and cut as below would succeed, from the same cause.

Home Correspondence.

Melons, to fertilise.—Among some experiments which I have lately witnessed is one which, if not new, is interesting. Mr. Aitkin, gardener at Pitfour, in Fifeshire, is in the practice of treading the soil firm into the frames where he grows Melons; and he does not water the plants until the fruit attains a large size. The plants are allowed to grow until they nearly fill the frame, when they are pruned back until they show fruit-blossoms on the lateral branches. The strongest flowers are selected, and fertilised in the usual manner, the male flower or anther being left in the female blossom. The corolla is then gathered together by the one hand, while the other immediately draws the dry mould over it. The fruit is then covered until it attains the size of an Orange, when it is placed upon slates in the usual way. Mr. Aitkin uncovered a fruit, ripe with in my presence, none of which were injured by damp; indeed, his Melons in their various stages were finely grown. They are nearly white when first exposed to light, but very soon become of a bright green. Whether this system of growing the Melon may turn out of utility or not, it may at all events increase the facility for keeping vacation frees; and although the soil may be too cretic with many growers, perhaps it may suit equally well to cover them with dry sand, &c. on the slates where they are commonly set. Mr. Aitkin considers the extra temperature of the soil advantageous in the diffusion of the pollen. May this not suggest experiments regarding fertilising many kinds of flowers in dark warm cases, &c. while the leaves grow in the light?—*R. Arthur, Waterloo place, Edinburgh.*

Bees.—It has been a matter of dispute among apiarians whether it is advisable or not to co-operate with the working bees by assisting them in their warfare at this season against the drones. Some have contended that it is not; and, certainly, in the manner in which it has been usually attempted, it had better be avoided. But in the method I am about to detail, I put at rest the question as to any injury to be sustained by a family of bees, from the sudden abstraction from it of all the drones it had contained. Those who have paid attention to the habits of these, when an attack has commenced on them by the watchers, must have observed a disposition to congregate together, as if for mutual protection, in a distant part of the hive. It occurred to me that this tendency to separation might be turned to account advantageously, if the suitable means were provided. The hive on which my experiment was tried was a collateral one, viz., a centre and two side-boxes. The centre and one side-box were occupied by the bees, and pretty well filled; the other side-box was empty, the bees not having access to it. I resolved on making this a place of refuge for the drones, if they chose, and, accordingly, on the morning of the 14th June, when the work of proscription had evidently commenced, I opened a passage throughout nearly the whole length of the bottom edge of the empty box, about half an inch high, but leaving all the upper openings closed. On looking into the windows of the side box at night, I found my expectations completely verified, for the drones, to avoid persecution, had availed themselves of this asylum, and were clustered together in a compact body, like a new swarm, at the top of the side-box; and in no part of the other two boxes could I discover one. What effect the pangs of hunger might subsequently have had upon them I know not: but during the time they had thus voluntarily expatriated themselves, the drones showed no disposition to return to the parent hive, but continued to hang motionless, as I have described. In this state I left them till the following morning, when I shut off the communication between the boxes, and removed the one containing the drones. These I speedily suffocated, with the exception of about 200 that escaped. I had sometimes imagined that the number of drones in a hive at this season is larger than common computation makes it, and this was a point I wished to determine. The dead drones were carefully counted, and amounted to rather more than 2200 in number, besides those that had escaped, and doubtless many more had previously fallen victims to the working bees; of the latter not a single one was found amongst the drones. On the same day all commotion had ceased in the hive, and the bees went with unusual alacrity to work, and did well. The first drones I had observed in the stock of bees subjected to the operation, were on the 23d of May, and after their destruction I saw not a single one until the 23d of July, when a second hatching of drones commenced; but the greater part of the grubs were ejected from the hive in that state. It is needless, perhaps, to say, that so complete and sudden an abstraction of the drones, entirely refutes the notion entertained by some theorists, that their presence is essential to the fecundation of the eggs, previously laid by the Queen; but it seems also to prove that they are as little required in the hive for the generation of the necessary degree of heat in the hatching season, as has been surmised, or why is it that in a hive subjected to the cooling process of ventilation, (and the hive I have herein referred to was one of these,) the destruction of the drones usually takes place earlier than in one left in its natural state of warmth?—*H. Taylor, London.*

Preserves, to Cork.—In the receipt for preserving Currants, resin is recommended for the corks, but the brown cement, Parker's or Roman, answers much better and breaks off when wanted without any trouble. Mix it thinner than for cement, and put some over the nose of the bottles. It soon sets. The writer has used it for years.—*N. O. P.*

Large Gooseberry.—On the 29th of July, Mr. T. Gibson, of Nottingham, found a London Gooseberry, grown in his garden, of the weight of 35 dwts. 12 grains.—*J. F. W.*

Asparagus.—I can, from long experience, confirm all you recommend as to the application of salt to Asparagus beds; and I cannot comprehend the objection to this saline manure; it must either result from ignorance, or from the use of the salt at an improper season. Perhaps those gentlemen who write against it, applied it whilst the roots were in a dormant state; if so, I do not wonder at the destruction of their Asparagus plants. Let them try it just as the roots begin to move in the spring, and let the application be renewed two or three times during the growing season, and let them always select a wet day for the work, and I will vouch for it they will soon become converts to the use of salt in a proper season; but other manure must not be forgotten. I have quite renovated an old bed by an abundant use of salt. For many years I have known sea-weed, and strong sea-sand, taken wet from the receding tide, used as a dressing for Asparagus beds, and I never knew those beds to fail. Now the secret of this application is in the saline qualities of the weed and of the sand, and not in any substantial quality of the sea-weed, for when this is dissolved there is nothing left for the earth of the beds to feed upon. An attentive observer of the natural history of the Asparagus plant cannot fail to discern the propriety of using saline manures in its growth; and the same treatment as to sea-weed and sea-sand applies to sea-kale. Both these plants are indigenous in Cornwall, and there is an island near the Lizard Point, called Asparagus Island, on which that plant grows, and which I have frequently gathered it. In heavy gales of wind the sea breaks over the part of this island on which the Asparagus grows. The soil is sand, and loose decomposed vegetable substances.—*Cornubiensis.*

Acclimatising Plants.—In reply to Mr. M'Intosh, who lately desired some one to give the results of their experiments on the above subject, I would mention that I have for several years preserved many of the different kinds of Fuchsias in the open garden, in all situations, during the winter, by simply cutting them down when they have done flowering, covering them over with a spadeful of gravel and a small slate, or flag. The slate, or flag, I find useful in preventing the heavy rains in winter washing away the ground, and, consequently, starving the plants, as in this part of the country we have generally very wet winters. Last year having too very tall Fuchsias (Globosa), above five feet high, I did not cut them down, but took them up, potted them, and placed them in a room without fire, near to a window facing the north; gave them very little water, and treated them according to my notions judiciously; but to my surprise, I found in the spring that the main stem was dead; a proof that I might as well have saved myself the trouble I had been at, by cutting them down in the open ground, as above mentioned.—*Chemical Jack.*

Humphreys's Soluble Compound.—If Mr. Humphreys has professed to sell a compound whose utility depends on constituents which it does not really possess, the exposure which he has received in your *Chronicle* is no more than he deserves: but if your remarks were intended to convey the impression that in consequence of the absence of phosphoric acid, his Compound was of no value, I am bound in fairness to say that I have made some experiments with it, which show that it does possess fertilising powers of a very powerful character. They may arise from the nitrate of ammonia, and he may charge an extravagant price for his mode of making up that material: I am not able to speak on those points. But I can say that on the 22d June, I applied the Compound in the proportion recommended on the label, to a Petunia, Verbena, Fuchsia, Pelargonium, Campanula, Pulteneea stricta, and though only one application has been made, the invigorating effects are most visible. The leaves are larger, and of a deeper green than other specimens exhibit which stood by their side, and were similar in every respect, as far as I could perceive, before I made the experiment. Yellow leaves on the Pelargonium in more than one instance were turned into a fine deep green.—*C. I. D.* [Our correspondent will see that we have never said one syllable against Humphreys's Compound as a manure: our observations have been strictly confined to the question, whether it contains phosphoric acid or not? Nitrate of ammonia is a substance extremely rich in nitrogen, and well known to be valuable if judiciously applied.]

Colours.—In Notices to Correspondents lately, you ask some one to answer "N. O. P.," who wants to know why colours made by man are different by candlelight from daylight, whilst in those of Nature, hardly any difference is perceptible? I beg to answer him by denying the latter part of his position. I took a candle into my greenhouse for the purpose of testing the fact, and found that Verbena Hendersonii, which is a beautiful purple, appeared of a decided crimson. Sollya heterophylla, and angustifolia, which are of a light and dark-blue, appeared of a pale and deeper lilac. The corolla of Fuchsia formosa elegans, and globosa, which is a deep violet, appeared to be a dull dark maroon; and finally, the yellow decaying leaves of a Tropæolum pentaphyllum were of a fine deep green.—*C. I. D.*

Planting Pines in Tan.—Acting under the advice given in Mr. Hamilton's treatise on the Pine Apple, I planted out, a few days after his work appeared, 24 fruiting plants in tan, or rather tan and decomposed leaves, under the expectation that they would produce me some tolerable fruit; but to my great disappointment the experiment is a complete failure; and on examination I find the plants have not made a single root into the tan, and even where young roots were formed, they have died off. Now, these plants have neither been too hot, too wet, nor too dry, the bottom heat having been about 80°, which is regulated by a tank, and the material they were planted in was just what Mr. H. would have selected himself, being tan and leaves that had been at work about six weeks, and just in a decomposing state, mixed with about one fourth of new tan, just to give life to the mass. Six lights of strong succession plants were planted but at the same time, eighteen plants in tan, and the remaining eighteen plants in soil; the plants in tan turned yellow in a fortnight, and have made a poor sickly growth, while those in soil have grown in great luxuriance, and will shortly show fruit; and finally, six other lights planted out with suckers on the old stools in November last, in fresh loam over a tank, are growing as well as could be

desired, and will make magnificent plants by autumn. Now, with these facts and experiments before me, I think I am justified in cautioning the readers of the *Gardeners' Chronicle* against planting in tan; for though I have no doubt of Mr. Hamilton's success, or sincerity in recommending it, yet as it differs materially in quality in different localities, and as it is considered of no fertilizing power, I am sure it will be better to plant out in soil, than to run the risk of failure with tan. It is but justice to say, the plants which the experiments were made with were not stove, and were subjected to ammoniacal vapour, produced by pouring gas-water in the tank for ten days, which destroyed the points of the leaves, but did not kill the scale. Had all the plants been in tan, I should have attributed the failure to the use of ammonia; but as those planted in soil grew rapidly afterwards, I should not be justified in doing so. Such is the result of my experiments; and although I do not think a bit the less of Mr. Hamilton's book for the failure, being convinced his practice is good, yet I think it best that these facts should be recorded.—*Fedax.*

Pine-apples.—Having called upon many gentlemen's gardeners during the last nine months, the general conversation turned upon the culture of the Pine-apple; and they, finding that I was an intimate acquaintance of Mr. Hamilton, of Thornfield, inquired particularly about his mode of cultivating the Pine; but I am sorry to say, that most of them appear stiff-necked and stubborn—hard of belief. They could not, or would not believe it possible to fruit the Pine from the sucker still remaining upon the old stool; and when I stated that it certainly is possible, and that annually, whereby no succession-house was required, they some of them broke out into a rage, saying—"Do you consider us all fools, and are we to abandon the practice that we have followed all our time, and our fathers before us?" This was very mortifying to me, having known Mr. Hamilton for these 11 years, 5 of which I was a near neighbour. Although these last six we have been separated, I am well aware of his method of cultivation, following the same practice myself when I have the opportunity; and I can assert, that when we were near neighbours, we were not excelled in the neighbourhood of Manchester; and I can safely add, that Mr. H. ably maintains his ground. I dare venture to predict that the gentlemen of Manchester will not be satisfied till their tables are supplied with as noble Pines as Mr. Phillips's. About a month back I called upon Mr. Hamilton, who immediately [illegible] my attention to a stock of Pines, saying—"You [illegible] have improved in my practice since you were here last"—it being then six years since I saw him; and, taking me to a pit *of* plants—one-half of which were in pots, the other half turned out of the pots, and planted in the tan, he said, "Do you perceive any difference in this pit of plants?" Yes, I replied; this half (pointing to those that were planted out) are a year older than the other. His answer was—"No; they are all of the same age; and these were planted out the first week in March last." We then went into the fruiting-pit, and some noble fruit there was. Mr. H. then said—"Do you recollect how heavy was the largest Montserrat that you saw here?" Yes, I said; it was 5½ lbs. "Well," he replied, "that was the heaviest that I ever grew whilst I kept them in pots; but since I have turned them out, I have grown the same sort to 7 lbs." I have no doubt that there are some of the present "shows" that will attain that weight; and be it remembered that these are all suckers upon the old stools, some of them being the third and fourth annual crop. Should any of my brethren of the spade doubt this, if they will take a trip to Thornfield, Mr. H. will have much pleasure in showing them the proofs upon the premises, and convince them of the facts; and surely facts are stubborn things.—*John Hayward, Summerhill, near Newport, Salop, July 29.*

A Habit of the Common Wasp.—I felt puzzled to find a reason why female wasps frequent the common Laurel early in spring. I had observed the fact so repeatedly that I determined to watch them; and then perceived their object was to obtain the nectareous juice secreted by the three or four glands seated on either side the midrib and near its base, on the under surface of the leaf. As I presume the wasps of other parts of England have the same habits as those which are born in this neighbourhood, the above observation may be serviceable to wasp destroyers. They have only to watch the Laurels in spring when the females are thus attacking them, and they may prevent the formation of as many nests as they shall destroy females at that season. A hoop gauze net, such as entomologists use, will readily serve for their capture.—*J. S. Henslow, Hitcham.*

Peas.—The notice of the comparative earliness of some of the new Peas, published in the *Chronicle* last year, seems to have induced rather numerous trials of the sorts I then named, and the result has been in some cases in favour of, and in others against the Early May, under which name, however, it is now evident that more than one variety is known. The Pea I have called Early May is known by that designation, and also as Clutton's Early, in this part of the country, and is identical with Cormack's Prince Albert; at any rate, I cannot perceive any real difference between them. I have been told lately that it was first brought into this neighbourhood from some part of Sussex, where it is called by some other name. In order further to test the earliness of this Pea, as compared with Farnes's First Early, I sowed both sorts side by side on the 14th of February, and their after-treatment was precisely alike; the Early May was fit for use on the 24th of May, the other not till the 30th, thus giving nearly a week in favour of the former. It should be known, however, that Farnes's [illegible] is a very desirable [illegible] and is a very desirable [illegible] the Early May. Another sowing on the 15th of March gave the same result. Shilling's Early Green is about a week or ten days later. I take this opportunity to recommend the Scimetar as a more productive variety than the well-known Green Imperial. The Auvergne is also an excellent bearer, each pod containing from seven to nine peas.—*J. B. Whiting.*

Whitney's Composition.—Have you had any complaints of Whitney's Composition rendering the calico tender? I covered half a greenhouse with Whitneyed calico, and the other half with the mixture recommended by "Devoniensis;" the latter is not quite so transparent, but the calico (which is a very good one, for which I gave 6*d.* a yard) is quite sound and strong, whilst the former is as tender as cap-paper.—*W. Wilkinson Platt.*

The Poinaise Heating.—The system of heating described by Mr. Murray in last week's *Chronicle*, appears to me as objectionable as the old flue mode of accomplishing this, without its advantages, and scarcely reconcilable with our present knowledge of the subject, at least if I rightly comprehend his plan. It appears to me objectionable to place the heated air at the back of the house; our common notions on this are to place the flue or chamber as near the front as possible; that would be fully recognising the principle which Mr. M. lays down as the basis on which his system is founded, as the coldest air is at the front of the house; but how this air is set in motion does not appear intelligible by the plan. The second objection which strikes me as fatal to his system, is that of "admitting fresh air from without, keeping up a healthy atmosphere," as indicated in the plan at C, C. Now, how does the air become unhealthy? Why, by the noxious gases which escape from the stove, as there can be no other means of contaminating it. Air is the same in all cases, unless it is rendered unwholesome by the decomposition of some material, such as tan or dung, or the noxious impurities generated by flues. If hot water was used in the same house, it would be quite unnecessary to think of admitting air from without.—*R. Glendinning.*—[We are informed by a gentleman who has seen this house, that nothing can exceed the health of the Vines.]

Local Horticultural Societies. — A Horticultural Society was formed at Torquay last summer, under the title of the "Torbay Horticultural Society," and held its fourth Exhibition on the 19th of July, 1844, when Mr. L., a jobbing gardener of Dartmouth, became a subscriber, and gained an extra prize for Martynia fragrans, which I consider very unfair. In the regulation for the Exhibitions, the fifth rule says—"No article shall be exhibited for a prize unless *bonâ fide* the property of the exhibitor, for two months before the days of exhibition." The plant in question was not the property of the exhibitor, but the property of one of his many employers. Is it right, or is it fair, for a jobbing gardener to exhibit in the same class with gentlemen's gardeners? If the Secretary tolerates such things as these, the Torbay Horticultural Society will soon share the fate of the Dover, Faversham, and Eltham Societies; namely, start up to-day, flourish to-morrow, languish, and then disappear. If this practice is not checked in time, the Society will die in its infancy. If the Society wishes to offer prizes for jobbing and for market gardeners, why not have a class for themselves in which to exhibit, as is the case at Chiswick?—*A Gardener, Dartmouth.*

Flower Gardens—The Season.—Reading the Calendar of Operations, relating to the Flower Garden, I find that the writer, like many others, has suffered through the influence of this uncongenial season. I cannot, however, agree with him in the statement respecting bedded out plants. Indeed, from what has come under my own observation, I am fully convinced of the contrary. Last week I visited the gardens of the Rev. R. Boyl, Marston Rectory; likewise those of S. F. Phelp, Esq., Warminster, besides those at Longleat, the seat of the Marquis of Bath—and it is really gratifying to witness the vigour and beauty of the various beds in the different flower gardens. I have been in the habit of visiting each of those places for some years past, but never on any former occasion did they appear so exquisitely beautiful; and much praise is due to the gardeners, who, through perseverance, have rendered them such, under most unfavourable circumstances.—*E. C.*

Societies.

BOTANICAL SOCIETY OF LONDON.

July 5. Dr. Bossey in the Chair.—Specimens of the following plants were exhibited, sent to the Society by Mr. Hewitt Watson:—Carex elongata (Linn.) found abundantly in Weybridge marshes. This locality is interesting to the metropolitan botanist; the nearest habitat, previously on record, being in the county of Salop.—A pubescent flowered variety of Bromus commutatus (Schrad.) found plentifully, along with the more abundant glabrous form, in a meadow by the river Mole, between Esher and West Molesey, Surrey. This variety affords another instance to prove the little importance which can be given to the character of smooth or downy flowers, as a specific distinction in this genus. It will form an addition to the London Catalogue of British plants, (b. subnens) to be entered under Bromus (1355) commutatus.—A specimen of Lolium multiflorum, the root of which was dug up, when in flower, in a sown field last year, and the plant is now copiously flowering in Mr. W.'s garden; this proving its perennial existence, although the alleged annual root of L. multiflorum has been considered the best distinction between this supposed species and L. perenne. The other alleged differences are equally invalid.—Garden specimens of Festuca pratensis (Huds.) and arundinacea (Schreb.), to show the strongly marked differences between them; the latter being three times the size, extremely hard to the touch, and very dissimilar in its flowers, and mode of inflorescence. In F. pratensis the branches of the panicle are erect after flowering, the palese or glumes obtuse and awnless, and the sheaths of the leaves nearly smooth. In F. arundinacea, the branches of the panicle are horizontal or reflexed, the glumes acute and awned, and the sheaths and leaves very rough. Mr. W. admitted F. loliacea and pratensis to be forms of one species; indeed, he had shown this to the Edinburgh botanists, just after they had printed their Catalogue, in which F. loliacea is kept as a distinct species, while F. pratensis is united with F. elatior, (Linn). But he was not yet prepared to combine all three, and the F. arundinacea likewise, under the one name of F. elatior, as is done by Mr. Babington. Mr. W.'s plant of F. arundinacea was originally brought to his garden from the Isle of Wight, and is now a large sheaf, with hundreds of flowering stems, four to seven feet high, and the root-leaves half a yard long.—A specimen of Œnanthe pimpinelloides (Linn.), to show the cylindrical form of the fruit, which exactly corresponds with that of the Sardinian plant (admitted to be the true species), except in having less callosity at the base. This was taken from a plant in Mr. W.'s garden, the parent of which had been brought thither from a hedge bank in the Isle of Wight. Mr. W. recognised a second species in Britain, after sent to him under the name of Œ. peucedanifolia, and readily distinguished by its turbinate or elliptic fruit, on extremely short pedicels, and more resembling Œ. globulosa, than Œ. pimpinelloides. The peculiar form of the root to some other specimens, resembling that of a Dahlia in miniature, induces a supposition that there may be a third species, although he has satisfied himself that the roots vary greatly with age and situation, and do not afford such certain characters for distinction as may be found in the fruit. The Œ. Lachenalii (of Babington's Manual) is apparently the species frequently sent under the name of Œ. peucedanifolia, though occasionally named Œ. pimpinelloides by English botanists. He would illustrate this subject more fully on another occasion. Specimens of the garden Fennel, to show the little importance to be attached to the difference of the stems being fistulous or filled with pith. These specimens were sections of stems arising from a single root, of different dimensions, but of nearly equal age and stage of development. Some of them (the thicker) were hollow, others filled with pith. A question respecting a distinction of species, between the wild and garden Fennels, had been raised in consequence of one author describing the stems as fistulous, while another finds them solid; but since both conditions can exist on one root at the same time, such a distinction would be quite inadmissible for a specific character.—A stem of Hieracium Lawsoni, which had borne 20 flowers, in Mr. W.'s garden, this spring; and others had flowered more numerously than this one. In the wild state on the Grampians (the locality from which the plants were brought three years ago,) this species has usually two, three, or four flowers only. He had seen a wild Irish specimen, with six or eight flowers. No care had been bestowed upon the plants in his garden, except occasional watering in dry weather, and removal of weeds from about them. He sent the specimens merely as an example of the little dependence to be placed on the number of flowers on the Hieracia; indeed, among the Compositæ generally. A wild plant, growing free from the interference of other plants about it, might also increase its flowers five or ten fold, as practical botanists must be well aware from observation. —Read, A Synoptical View of the British Fruticose Rubi, arranged in Groups, with Explanatory Remarks, (Part 4,) by Edwin Lees, Esq., F.L.S. The paper was accompanied by drawings and specimens.

BOTANICAL SOCIETY OF EDINBURGH.

July 1.—This, the last meeting for the session, was held in the Royal Botanic Garden, Professor Graham in the chair. The Treasurer read a paper on three Genera of Desmidieæ, by Mr. J. Ralfs, Penzance, viz., Desmidium, Gloeoprium, and Schistochilum. Mr. J. M'Nab read a portion of his Journal of a Tour in the United States and Canadas. In the last notice, Mr. M'Nab gave an account of the excursion from Albany to Troy, and thence to Stillwater, with notices of the most interesting plants observed during the journey thither: the present portion is chiefly confined to observations on the Botany of the same district. July 15. Few species rewarded their exertions, the greater portion being out of flower; of those gathered, the most attractive were Lobelia cardinalis, and Habenaria fimbriata, both in great abundance, the rich spikes of scarlet flowers of the former being admirably contrasted with the delicate purple blossoms of the latter; these two species formed the bulk of the flowering plants; mixed with them, but more sparingly, Habenaria lacera and Neottia cernua occurred, with Apocynum androsæmifolium, the latter being the most abundant, and covered with a beautiful coleopterous insect, which appeared to be peculiar to it. On the sloping banks of the river, in thickets of Sumachs, Hazels, Willows, &c., a gigantic species of Solomon's Seal, *Polygonatum latifolium*, was observed; some of the specimens measured seven feet nine inches in height, with roots four inches in circumference. In several places the ground was so matted over with the stems of the Poison Oak, *Rhus toxicodendron*, that the hands of the party were much blistered in

endeavouring to extricate themselves. July 16. Having preserved a calm, the party proceeded about two miles down the river; during this short voyage they observed vast quantities of the shells of the fresh-water mussel, covering the banks newly killed by the river's edge; they had been collected by the musk rats, with which the banks evidently abounded. At this place the rapidity of the stream, which had hitherto prevented the growth of aquatic plants, became much diminished, and they now observed large portions of its surface covered with Nuphar Kalmiana and advena, together with Nymphæa rosea, all beautifully in flower, and growing from a depth of eight feet. Overhanging the banks on both sides of the river, Salix petiolaris was in fine condition, its broad, leafate stipules adding much to the beauty and singularity of its appearance; here also, some fine specimens of the Virginian Poplar, *Populus monilifera*, were seen: the largest stems measured were nine feet in circumference, and about 70 feet in height. Leaving Stillwater the party proceeded by canal to Whitehall; on the banks of the canal, and extending over the neglected fields, such quantities of the Great Mullein, *Verbascum Thapsus*, were observed as to give the idea of its having been sown for a crop: the fact of its growing on the soil which had recently been thrown out of the canal, as well as on the sloping banks, convinced them that the seed must have lain buried in the earth, probably for a long series of years, and that, therefore, it is not likely, as has been generally supposed, that this plant has been introduced by the emigrants, but rather that it is indigenous to the country. The common St. John's Wort, *Hypericum perforatum*, was also extremely abundant in this district, although sparingly seen before, and is described by Mr. M'Nab as one of the greatest evils the American farmer has to contend with, being supposed to be highly injurious to cattle, especially horses, causing blindness, which prevailed in many parts to a fearful extent. On reaching Whitehall, situated at the southern extremity of Lake Champlain, two remarkable species of Ferns were observed for the first time; namely, Asplenium rhizophyllum, and Aspidium bulbiferum, the former growing on the surfaces of moist rocks, where it throws out its fronds, which take root at their extremities; while the latter bears a number of small bulbs along the rachis which, when mature, fall off and vegetate in the crevices of the rocks. Many other interesting plants were observed, but few of them in flower, with the exception of Rubus spectabilis, Desmodium acuminatum and canadense, and a few others. Mr. M'Nab afterwards exhibited several specimens of Gooseberries and Currants, which had been kept for the last two years in glasses, containing water only, in which they had now matured their fruit for the second time; and it was remarkable that the Gooseberries (Yellow Amber), and the Red and White Currants, were as highly flavoured as the same sorts under ordinary treatment.—Mr. Trevelyan exhibited specimens of some remarkable varieties of Taraxacum officinale, found on the sandy beach near Arbroath, and a curious variety of Aspidium filix fœmina from Braemar, having the frond branched at the extremity; the specimens were afterwards presented to the Society.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

July 20.—This Exhibition of plants and promenade took place at the Society's Garden, Inverleith. The day proved remarkably favourable, and the assemblage of company was brilliant. The plants were confined to the new Hall, the centre and side-tables of which were completely filled with choice exotics in flower. The large marquee which used to occupy the principal lawn having been removed, the whole of that beautiful piece of Grass was left free to the promenaders. This was not a competition meeting, and no medals were, therefore, voted; but honorary rewards were made to the chief exhibitors. The nurserymen contributed largely. Messrs. Dickson and Son sent a magnificent collection, including many of the new Pelargoniums and Fuchsias; among the latter, Edina and Exoniensis, the former a seedling raised at Inverleith, and remarkable for the large size of its blooms.—Messrs. Lawson and Sons exhibited a tray of novelties, including Quercus Mirbeckii, Daubentonia tripetiana, and Cercidendron brevifolium.—Messrs. Purdie and Merrilees showed some well-grown Heaths, and an admirable Lilium lancifolium cruentum, having 17 flowers and buds on one stalk.—Messrs. Carstairs, Kelly, and Co., sent a collection of greenhouse plants, including Hydrangea japonica and an admirably-flowered specimen of Boella ciliata, rarely seen in such perfection. From the same establishment was a plant of Myatt's Prince Albert Strawberry, remarkable for combining the qualities of high flavour with fruitfulness.—Among the productions of Amateurs, was a collection of Seedling Calceolarias, raised by Mr. I. Anderson. Several of these were fine, and in particular Prince Albert, King of Saxony, Duke of Buccleuch, Mary Queen of Scots, Orion, and Cupid, now exhibited for the first time, besides Queen Victoria, General Robertson, Countess of Rosslyn, Hon. Mrs. P. Ramsay, and Lord Justice-General, which had been shown at a former meeting.—Mrs. R. Haig sent tastefully arranged trays of Ericas, Geraniums, and Cranulas, with handsome flowering specimens of Cattleya Forbesii, Oncidium papilio, Erythrina lancifolia, and Calathea zebrina.—From Melville Castle were well-grown Heaths; also trays containing British and exotic Alpines, besides well-managed plants of Stanhopea insignis and Miltonia spectabilis.—Some admirably grown Heaths were sent from Rosepark, particularly Erica ventricosa pruganera, and E. tricolor dumosa; and a beautifully-flowered, though small, Pimelea spectabilis, and a new sweet-scented Verbena.—Dysticium Sieberianum had two specimens of Achimenes longiflora, the largest measuring 6 feet in circumference round the branches, and marked as a cutting of last year; together with two very large and high-coloured Cockscombs, said to be the finest arborea.—Dr. Neill showed a remarkably fine Oncidium pulvinatum, having a flower-spike 7 feet long, magnificently clothed with orange and yellow blossoms; besides well-grown plants of Zygopetalon maxillare and Calanthe veratrifolia.—Mr. Oliver exhibited some capital greenhouse plants, among which Phœnocoma prolifera, Erica princeps, and E. inflata, were truly striking.—Mr. Keith sent seedling Pelargoniums, and a tray of lovely greenhouse plants.—Captain Falconar exhibited 80 varieties of French, Hybrid China, and Moss Roses.—From General Robertson was Viscaria oculata, a new hardy annual.—From Mr. Henderson were double Marigolds, Dahlias, and a well-grown specimen of Gesnera fasciculis.—Mr. Symington showed Fuchsias.—Mr. R. Girdwood, a fine flowering plant of Phlox bicolor, newly imported from the United States.—Mr. Edmond showed Pinks; and Mr. Cushnie, two fine specimens of Statice puberula, covered with flowers.—An Oleander-plant from the Society's garden excited much attention, being 5 feet high, and in full flower, although it had been hanging in the air for the last three years, and supported wholly by moisture supplied by a syphon of worsted threads, communicating with a small suspended jar containing water. Among other choice plants from the same collection were Nepenthes distillatoria, 7 feet high, and displaying its curious pitchers; large flowering specimens of Lilium japonicum and Cereus speciosissimus; with Campanula stricta and Drymonia punctata.—Mr. Montgomerie sent specimens of the Precoce de Tours Plum, from an open wall without artificial heat; the fruit had already made considerable approach to ripeness, and is found to be earlier, on the west coast of Scotland, than the White Primordian or than Wilmot's Early Orleans.—Specimens of ornamental flower-pots, and vases for containing flower-pots, constructed of zinc, were exhibited by Mr. Macintosh, of Edinburgh.

Reviews.

Essays on Natural History, chiefly Ornithology. By C. Waterton, Esq. 12mo. Longmans.

Who is there that loves the woods and the fields, and the living things which fill them, who does not admire the honest, straight-forward zeal of Mr. Waterton? which, whether directed towards the maintenance of his religious and political opinions, or the description of his adventures, or the elucidation of the habits of his winged favourites, is always full of entertainment and instruction. We are neither Catholic nor Jacobite; but the best Protestant, and staunchest Hanoverian, can scarcely read Mr. Waterton's autobiography, without having his misgivings as to the possibility of either Reformation or Revolution having been effected, had all the friends of the fallen causes possessed his energy and honesty of purpose.

What renders Mr. Waterton so particularly agreeable is, his sterling English feeling; his unconcealed contempt for *namby pamby*, in thought, word, or deed; and the skill with which he brings his great powers of observation to bear upon the subjects of his pen. With him there is no trusting to other people, no borrowing from books, no repetition of the hackneyed tales of credulous naturalists, but all is as pure as the air that blows over the lake of Walton Hall. The reader feels that he is a man to be implicitly trusted; and no one rises from the perusal of his writings, with a doubt about the perfect truth of his narrative.

The present volume is an instance of his benevolent character. It is published for the benefit of Mrs. Loudon and her little girl, and we have no doubt that it will prove a very effectual assistance to them. We can confidently say, that it will amply repay the reader for its perusal. It treats too little of botany and gardening, and too much of owls and rollers, squirrels, wrens, robins, swans, Canada geese, and caymans, to furnish us with much that can be advantageously extracted. The following extracts will, however, as we hope, tempt the lovers of natural history to become acquainted with the remainder of the book:—

"*The Wren, the Hedge-Sparrow, and the Robin.*—The song of these three well-known warblers may be termed perennial. Formerly it was very rare for me to hear the notes of the second whilst the storms of winter raged through this little valley. But now it is otherwise; for the yew shrubs, which have grown up into a spacious cover, seem to be more congenial to the habits of the hedge-sparrow than any other evergreen; and it may be seen perched near the top of these, and warbling there, from time to time, in every month of the year. Here is a problem to be solved in the economy of these three soft-billed little birds, before we can safely come to the conclusion that severity of climate, and want of food, are the real causes why our summer birds of passage leave us shortly after the sun has gone down into the southern hemisphere. Like them the wren, the hedge-sparrow, and the robin, are insectivorous, and they differ not in the texture of their plumage; still they do not accompany their departing foregoers, but prefer to remain in this cold and stormy quarter of the world, throughout the whole of the year. They may certainly suffer more or less during the chilling period of frost and snow; nevertheless, their bread is always kept up; and we find, on the return of spring, that they have not suffered more than others which are apparently better enabled to brave the rigour of the English winter from their size. There is yet another point which wants settling in the habits of these birds. I allude to their song. When we are informed that inspiration is the main inducement to melody in the feathered tribe, we have only to step out after sunrise into the surrounding evergreens, and there we are sure to hear either the wren, the hedge-sparrow, or the robin, in fine song, although not a single twig has been laid, or a piece of Moss produced in furtherance of a nest, wherein to raise their future young. Certainly, in this case, neither love nor warmth could have had any hand in tuning the winter lyre of these little sons of Orpheus. The wren is at once distinguished in appearance from our smaller British songsters by the erect position of its tail. Its restlessness, too, renders it particularly conspicuous; for, when we look at it, we find it so perpetually on the move, that I cannot recollect to have observed this diminutive rover at rest on a branch for three minutes in continuation. Its habits are solitary to the fullest extent of the word; and it seems to bear hard weather better than either the hedge-sparrow or the robin; for whilst these two birds approach our habitations in quest of food and shelter, with their plumage raised as indicative of cold, the wren may be seen in ordinary pursuit, amid icicles which hang from the bare roots of shrubs and trees, on the banks of the neighbouring rivulets; and amongst these roots it is particularly fond of building its oval nest. The habits of the hedge-sparrow are not quite so solitary as those of the wren. It will approach the window in cold weather, and there pick up a scanty meal with the robin, the chaffinch, and the house-sparrow. Still, we very rarely see three hedge-sparrows in company. As these birds inhabit low shrubs and the bottoms of Hawthorn fences, and are ever on the stir amid old pieces of wood and lumber, put apart for the use of the farm-yard, we cannot be surprised that they, as well as the robin and the wren, which are fond of such localities, should fall an easy prey to the cat, the weasel, the foumart, and Hanoverian rat, which last all the world knows to be uncommonly ravenous. The last of this sweetly-warbling trio, whose habits I am attempting to describe, is pretty cock-robin, the delight of our childhood, and an object of protection in our riper years. Wherever there is plenty of shelter for him his song may be heard throughout the entire year, even in the midst of frost and snow. In the whole catalogue of British birds, cock-robin is the only one which in his wild state can be really considered familiar with man. Others are rendered tame by famine and cold weather, and will cautiously approach the spot where food is thrown for them; but the robin will actually alight upon your table, and pick up crumbs on your own plate. When I have been digging in the pleasure-ground he has come and sat upon my spade; and by every gesture proved his confidence. You cannot halt for any moderate time in the wood but cock-robin is sure to approach, and cheer you with an inward note or two; and on such occasions he has more than once alighted on my foot. This familiarity is inherent in him, and not acquired. I am not acquainted with any other wild bird that possesses it. In Italy this social disposition of his does not guarantee him from destruction by the hand of man. At the bird-market near the Rotunda in Rome, I have counted more than 50 robin-redbreasts lying dead on one stall. 'Is it possible,' said I to the vender, 'that you can kill and eat these pretty songsters?' 'Yes,' said he, with a grin; 'and if you will take a dozen of them home for your dinner to-day, you will come back for two dozen to-morrow.'

"*The Yew tree.*—I never cast my eyes on the mouldering fabrics which once adorned this land, without renewing my veneration for the memory of the holy and useful monks who have gone before us. There is still enough left of the falling walls to show how much these faithful friends of the poor and needy must have been esteemed through the whole extent of the nation; and when I sit me down under the dark foliage of some ancient Yew-tree, which has escaped the fury of the destroying Vandals, and think of the miserable state to which the sons of poverty are now reduced, I cannot help heaving a sigh, whilst my very heart itself seems to sink within me. I am extremely partial to the Yew-tree. It has already repaid me for the pains which I have taken in its cultivation; and when I resort to my usual evening stand, in order to watch the flocks of sparrows, finches, and starlings, whilst they are dropping in upon the neighbouring Hollies, I feel not the wintry blast; as the Yew-trees, which are close at hand, are to me a shield against its fury; and, in fact, they offer me a protection little inferior to that of the house itself. I have not been sparing in the arrangement of ornamental Yew-trees. Just 60 yards from the bridge, which joins the island to the main, there is a Yew-tree crescent, 300 feet in extent; and not far from this there are some fine clumps of the same plant, producing a very pleasing effect. Should he who will succeed to them when I am low in dust have the philosophy to set at naught the modern disapprobation of ornamental planting in lines and circles, he will always command the sweet warblings of unnumbered songsters, from earliest spring to latest summer; for the Yew-tree is a kind friend to the feathered race; and the wren and the hedge-sparrow will sing sweetly amidst its foliage throughout the autumn, and even after the winter season has set in. The cultivation of the Yew-tree is sure and simple. It will thrive in any soil that is clear of swamps; but, the richer the soil, the richer is the appearance of its foliage; and if the planter will trench his ground from two to three feet deep, throwing back into the bottom the worst of what has been removed, and reserving the best for the

upper climates, but it may be handsomely managed as a rapid growing shrub. Although the Yew-tree is a hardy plant, and found in cold regions (Norway, Russia, &c.), still it will not resist severe frosts, especially when scattered sailing time on the bleak hill exposed to the wintry blast. Our readers will have no trouble in finding out the keenly on its foliage, and under the skin which is exposed to their fury in thin and wrinkled leaves. Look at the face of a metropolitan alderman made fat on Turtle, Sunday morning, after having complied through the week days of unmitigated fasting. Provided you do not care about having your Yew-tree in all the exuberance of unpruned vegetation, you may apply the pruning knife and shears with a safe and an unsparing hand; for the Yew-tree will submit to curtailment with good effect, and without any apparent diminution of vitality. If we clip its southern side in imitation of a wall, and allow that which faces the north to flourish in its natural state, we shall have from the same line of trees a walk impervious to the blast of Boreas for ourselves, and a provision of berries for the birds, at a time when their more ordinary supply of food is considerably on the decrease. Charming is the appearance of the Yew-tree after the sun has passed the autumnal equinox. The delicate crimson of its fruit, with the dark-green leaves behind it, produces an effect so pleasing to the view, that it can scarcely be surpassed by anything which the southern forests present to the lover of Botany, as he wanders through their mazes."

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

PENTAS CARNEA. Flesh-coloured Pentas. (*Greenhouse Shrub.*) Rubiaceæ. Pentandria Monogynia.—This beautiful half-shrubby plant has been lately introduced to this country from the Continent, and grown in several of the gardens and nurseries about London under the name of Spanea carnea. It was first received at the Botanic Gardens of Kew, from Mr. Mackoy of Liège, and has since been obtained by Messrs. Rollisson and others, from the Jardin des Plantes at Paris. No memoranda were furnished with these plants respecting the native country of the species, and we are, consequently, unable to state with certainty what part of the world claims it as its production. Another species of the genus, P. parviflora, having been discovered by Dr. Vogel, in the late Niger expedition, growing in the western part of Tropical Africa, near Acera, and other plants nearly allied being found in the same neighbourhood, Sir William Hooker, in the "Botanical Magazine," conjectures this to belong to the same locality. As an ornamental plant for the stove, or possibly for a warm greenhouse, this will be hailed as an acquisition of some importance. It has an excellent robust habit, and produces a number of partially-spreading branches, forming a handsome bushy plant, clothed with an abundance of large, broad foliage, concealing the stems to the very base with its lively verdure. These branches usually bear flowers as they are formed, even when the plant is in an exceedingly dwarf state, without appearing to have any injurious effect on the continuing growth of the specimen. The blossoms are collected into corymbose clusters and stand erect, displaying their lovely soft flesh-coloured hue to the utmost advantage. When the flowers are first developed they are very pale, but gradually acquire colour with exposure. If the plant is kept growing in a favourable situation, it will continue to blossom, with the formation of new branches, for the greater part of the year; and such is the rapidity of its growth, that it will form a large bush in the course of a single season. Like most soft-wooded plants of quick growth, it requires a rather large pot, and a strong soil, rich in nourishing properties. And it will probably be beneficial to use an occasional application of manure water, to increase its vigour, especially where large specimens are desirable. In the summer months there is little doubt that it will be found to succeed satisfactorily in a close greenhouse, although in winter and spring a little more warmth is necessary. It is easily propagated by taking off the extremities of the young shoots as soon as they have acquired a little firmness; and, inserting them in a pot of sand, covered with a bell-glass, and placed in heat, they will take root in ten days or a fortnight, and should be immediately potted into separate pots and encouraged to grow. The generic name, Pentas, has been applied by Mr. Bentham, from the division of the corolla being quinary instead of four-cleft, as in other allied genera. Although general, this is not constant, as flowers on the same head are four and five-parted. Three or four plants, which have hitherto been arranged under other genera, are suspected by Mr. Bentham to belong rightly to this.—*Paxton's Magazine of Botany.*

STERNBERGIA SESSILIFLORA Hartwegii. Mr. Hartweg's Stenomesson (*Greenhouse bulb.* Amaryllidaceæ. Hexandria Monogynia.—A pretty little bulbous plant found by Mr. Hartweg at the Hacienda del Ixio, on the ascent to Antisana, in the province of Quito, at the height of 11,800 feet above the sea. It has pretty orange-coloured nodding flowers, growing in pairs. It should be potted in a compost consisting of peat and sandy loam in equal proportions. In spring and summer, while the plant is in a growing state, an ample supply of water should be given; but in autumn, when the leaves begin to die off, this should gradually be withheld, and for a few weeks in winter kept quite dry. The temperature in a warm greenhouse will be quite sufficient.—*Botanical Register.*

Garden Memoranda.

Mr. Glendinning's Nursery, Chiswick.—This nursery, although one of the oldest in the neighbourhood of London, had almost dwindled into nothing; but during the last season it has undergone great improvement; and several hothouses and new erected for the cultivation of exotics. The houses, although not large, are admirably contrived to admit of watering and inspection; indeed, every plant may be said to be under the eye of the cultivator. The plants are, nevertheless, at the same time, all near the light, which is a most important point in hothouse building, and one too frequently made of secondary moment—especially when architects are employed in the erection of these structures. The propagating-house is well contrived for the purpose, and is heated by one of Eldridge and Healy's improved boilers, and the bottom heat is communicated by hot water, the iron gutters manufactured by the same party, which answers admirably. Mr. Glendinning approves of iron gutters in preference to those formed of brick, and rendered water-tight by cement; and his reasons are, that hot-waterers them more economical and more durable, and also much less likely to leak. Besides, in case of any alteration, iron gutters can be removed in a very short time, and again re-erected, without any new arrangement of brick and cement, or the material without total destruction. The gardening world, therefore, owes much to Mr. Glendinning for his ingeniously brought iron gutters. [illegible] the atmosphere of horticultural [illegible] plants in the several houses were in [illegible] numerous many new species. Among others we remarked Hallia fascida, covered with beautiful cymose flowers, about the same size, and having exactly the appearance, except in colour, to those of Chorozema; cordata was also in bloom Clerodendron infortunatum, a most beautiful species, having large and very brilliant clusters of scarlet flowers. This is a great acquisition to gardens, as it is a free grower, and produces a fine head of bloom while in a very young and dwarf state. With regard to treatment, it likes plenty of moisture during summer, and does not require a high temperature, which is apt to cause it to grow tall and straggling. Gloxinia Cartoni was blooming finely here, as was also another variety, named bicolor, having pretty lilac blossoms with a white centre. In this house Mr. Glendinning called attention to what he considered to be a new yellow-flowered Rondeletia, clothed with abundance of fine foliage, about 6 inches long, but it was not in bloom. In the same collection was the charming Thunbergia chrysops, remarkable for its "eye of gold in a field of the richest purple." This being of a somewhat shrubby nature, appears to be of a more permanent character than other species of the same genus. Hindsia longiflora, a greenhouse plant of considerable beauty, resembling the old Bouvardia triphylla in habit, and requiring nearly the same treatment, was producing its purplish-blue flowers freely; as was also Gloxinia magnifiora, a new variety with delicate pink blossoms; and near to this was situated a noble Statice arborea, producing three fine spikes of bloom. In the same house we remarked a plant of Gardenia Sherbournia, a handsome stove climber, having large bell-shaped flowers, white on the outside, and of a deep red within, which forms a fine contrast with the beautiful dark-green foliage. Among other things we observed Habrothamnus fasciculatus, which, from having the shoots well stopped in, was forming a fine bush covered with large healthy foliage. When in flower this presents an unbroken mass of crimson blossoms, and is one of our most beautiful greenhouse plants. Here was likewise a Gesnera, said to be G. macrorhiza, producing large bright-scarlet flowers in pairs; and in the same house was, also in bloom, a plant of Lisianthus glaucifolius. The collection of Heaths was in fine condition, comprising upwards of 200 of the best kinds, and including some scarce and valuable sorts. We remarked among others the beautiful free-flowering Savileana, good plants of Ampullacea, Lawsonii, with small pink blossoms; Jasminiflora alba, which is one of the best Heaths; and another variety of Jasminiflora named Vittata, together with Irbyana, and several varieties of Macnabiana, with many others in good health and equally indicating judicious management.

Miscellaneous.

The Cineraria, and its Culture.—The name Cineraria has been given after the Latin word *cineres*, on account of the ash-coloured down which covers the under side of the leaves. The most beautiful sorts of this genus come from the Cape and the Canary Islands; they have been successively introduced into Europe during a period of about 60 years. The leaves of some of them are formed like those of the Poplar (populifolia), others are in the form of a heart, and some again have a down upon their leaves (lanata); there are also certain sorts, amongst which is cruenta, whose foliage has a smooth surface. By the mutual fecundation of these different sorts, first the English and afterwards the Belgians, have raised numbers of novelties, each more beautiful than the other. These have again successively given place to other newer and more interesting kinds. It is thus that we have seen mentioned in catalogues, for about 10 years past, during which this plant has occupied attention, at least 300 varieties. Nevertheless, of these only a few are now considered worthy of cultivation. At the present time there are imported new varieties quite distinct from one another; this number is, however, very inconsiderable, and does not surpass 25 varieties. These beautiful Cinerarias, some of which have been obtained from seeds, in Belgium and also in France, will serve as new types from which to obtain, by judicious fecundation, farther improvements in this beautiful genus. Regarding the qualities of the Cineraria as a florist's flower, I have remarked for some years at the Exhibitions of Brussels, Ghent, Malines, Liége, and Antwerp, that skilful florists attach the greatest importance to those kinds which carry themselves well. They prefer those which flower abundantly, and whose flowers are large and well-made; that is, whose petals are nearly broad enough to fill the spaces between them. To these qualities a good variety should also add beauty of tint, and richness of colour. The improvements of which Cinerarias are susceptible, consist in obtaining the petals broader, and having novelty of lively and brilliant colours, and at the same time possessing the qualities above mentioned. This plant is not difficult to cultivate; nevertheless, there are some rules to follow, if well-grown plants and an abundance of bloom are to be obtained; you must prepare beforehand at least a year, if you wish to be successful. Young plants in small pots, bought in from nurseries, about the end of March, may be placed in a greenhouse, where they will not be far from the glass, but they should not be allowed to receive directly the rays of the sun. The plants ought to remain for some days in this situation, and in the mean time soil may be prepared into which to repot them. This should consist of thoroughly decomposed leaf mould, mixed with an eighth part of soil from an old hot-bed. After the first potting, when the plants have taken certain hold, repot them again, taking out the crocks without disturbing the roots. As the plants become larger, the compost may be made richer, and mixed in the proportion of about three parts of leaf-mould to one of soil. The first potting should take place about the 15th of April, and the second in about a month afterwards; at every potting take a pot broader and higher by half an inch than the ball of the plant, and see that the upper roots are not covered too deeply with soil, for that is hurtful in general to all plants. At the commencement of June every Cineraria should be stinted and exposed to the air, placing them where the heat of the sun does not penetrate upon them with too much force. During the months of June and July, great care should be taken to water them, particularly in the afternoon, and when the sun has ceased to shine upon the plants. They may also be watered in the morning before 8 o'clock, without any danger. Towards the end of August, or a little earlier, you will observe at the base of many of the plants little shoots which proceed from the roots, the stem, and the axils of the lower leaves. They speedily root in the upper layer of the ball, and should be carefully taken up, as much for multiplying the specimens, as for clearing the plants of young suckers, which would otherwise take away a part of the sap which the plant requires to strengthen it, in order to become a good specimen. If Cinerarias are treated in this manner, they will be covered the following spring with rich and abundant flowers. The little suckers taken up may be put into pots of a proportionate size, placed in a hotbed and shaded from the sun, where, in 15 days at most, in August, the roots will show themselves all round the ball. They should then be put into larger pots, placed close to the window of a greenhouse, and exposed to full light; where they may remain until spring. The parent plants should be put into a cool greenhouse, or frame, about the 15th of October, and remain there all the winter; they may receive as much light, air, and sun, as possible. Towards the end of January place them farther from the glass at the top of the house, and continue to give them as much air as possible in fine weather. If it is desirable to delay the time of flowering a month or six weeks, pot the plants again into larger pots by an inch, before the flower-stalks rise, and the flowers appear towards the beginning of March; large specimens remain in bloom at least six weeks. Cinerarias fertilise readily, and seed abundantly, particularly when they are placed in a dry situation, where they have air, and every morning receive a sufficient watering. As soon as the seeds are ripe, they should be gathered and put into a dry place, but only for two or three days. Afterwards you must clean the seeds well, and sow them immediately in very fine and rather sandy leaf mould. They will come up in a fortnight or three weeks afterwards; the young seedlings should be pricked out as soon as they have two well-formed leaves, and two others are beginning to show themselves. These seedlings should be placed for eight days in a hotbed, sufficiently warm to induce them quickly to strike root again. As soon as the young plants have unfolded and formed their first leaves, they ought to be potted afresh, and eight days afterwards placed in the open air, in order to strengthen them before autumn, so that they may the better endure the winter. The seedlings may afterwards receive the same treatment as older plants. A great number of these seedlings, provided they are well taken care of, flower in the spring. You cannot be too careful to take exact notes of seedlings raised from different varieties, until you ascertain which sorts give the best result. If green-fly attacks the plants during winter, that insect may be speedily destroyed, without danger to the plant, by fumigating the house with tobacco-smoke. In spring this should be done very gently, for if the tobacco is too strong, the plants will be injured by it, and perhaps perish. You can never throw tobacco on them in the form of snuff or otherwise, for the contact of the tobacco would quickly kill the Cineraria. It is, therefore, in spring much better to destroy the green-fly with the fingers, as fast as it appears. In fact, unless you have a greenhouse expressly for this sort of plant, you cannot burn tobacco without hurting other specimens, which are not at the time in flower. The Cineraria has very little scent; it does, however, very well, while in flower, to be placed in the window of an apartment exposed to the sun. It flowers there as well as in a greenhouse for a considerable time; on fine days in April and May, admit air into the room, at least one hour every day. In this point of view it is, perhaps, the most convenient for a drawing-room, and for this reason it may be expected to become a general favourite.—*J. de Jonghe, in Revue Horticole.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

STOVE-PLANTS which flower late in the autumn, and especially those that may be taken to the conservatory to bloom, should now, or very soon, be in their flowering-pots. The Eranthemum pulchellum, several Justicias, Aphelandra cristata, Poinsettia pulcherrima, Æschynanthus grandiflorus, and many more of that character belong to this class. Another very essential point to be observed with stove plants in general, which are removed to the conservatory while in flower, is to have the compost lighter for them, and not give them more pot-room than will just keep them healthy, with the assistance of liquid manure, as plants of this nature suffer very much in a cool conservatory late in the season, if they are growing in heavy rich composts, and in large pots; whereas, in a stove, that would be the right way to make them flourish.

Conservatory.—No matter how soon in August the Dutch bulbs for very early forcing are potted; the more roots these bulbs make before they are brought into heat, the better. In Holland, the bulbs for the first crop are well established in pots before we begin to think of "ordering" ours. Geraniums, Cinerarias, Chrysanthemums, and some of the Cornwas, will now

extent more heat; and with a little forcing they may be brought into flower a month sooner. Look well to your late autumn-flowering plants for cut flowers; Heliotrope, Sweet Briar, Mignonette, Lemon-scented Verbena (Aloysia), and Fairy Roses, with the "Hose-in-hose" Pelargonium," are always inestimable for bouquets after the middle of October, or as soon as the early frosts nip them out of doors Look to every plant like pet cats, and these order such and such treatment as the different cases may suggest. This has been a trying season for the good gardeners. Besides thus exercising our patience, a large addition is made to the stock of our experience, upon which we can fall back more readily in future —*D H*

II.—FLOWER GARDEN AND SHRUBBERIES

Out-door Department

In answer to the question propounded last week—What is to be done to counteract the evil consequences attendant upon our flower garden decoration by cold, wet, or dry seasons? it may be remarked, that an improvement will be effected in the first place by a thorough drainage and pulverisation of the soil to the depth of at least two feet This will allow of a free percolation and distribution of moisture throughout the whole mass of the soil, and that not only of the moisture which falls in the form of rain, or is supplied by the hand of man, but also of the moisture which is ever finding its way through the crust of the earth by capillary attraction Nor is it moisture only which escapes more freely by a deep stirring of the soil and thorough drainage, but also terrestrial heat All practical men know the advantage of deep trenching for kitchen garden crops, especially in dry seasons, and what is good of one crop must also be good of another. Now where flower gardens are situated on a subsoil of strong retentive clay, as is the case here, it will be the best to remove it to the depth of two feet, placing six or eight inches of brick rubbish or rough stones over the bottom of each bed, and making the remainder good with fresh top and pit loam To do this in large gardens will be attended with considerable expense and labour, and therefore as a makeshift it will do considerable good to remove only a part of the bad subsoil, and then mix the remainder with brick rubbish and half-decomposed vegetable refuse However, to follow this matter out satisfactorily will require more room than I can spare this week, and I therefore must leave the rest for another time.

Rosery—Proceed with budding where the bark rises freely, but if it is dry defer the operation until we get more rain We have lately been over our best Roses, and instead of cutting out the dead flower buds have trimmed out all the weak shoots, only leaving such as will be required at the winter's pruning The buds on these left will get much stronger in consequence, and we calculate upon a finer bloom than usual next season The half ripened wood of Chinese Tea, Bourbon, and Noisette Roses strike freely at the present time, and until the end of September, if placed on a little gentle bottom heat; and these are things which every garden ought to be covered with —*W P A* [Rabata last week.—In line 19, for "under ones," read "tender ones."]

III.—FLORISTS' FLOWERS

Tulips—These bulbs may now be divested of their superfluous skins, and thoroughly cleaned, whenever the florist can spare time. *Dahlias*—Should be constantly watched and regularly tied as they advance, as the side shoots are extremely apt to be wrenched off by the wind. *Pansies*—bed may continue to be sown, and beds made of rooted cuttings *Pinks*—Whilst the weather continues showery plant out the pipings They may also still be struck with success *Carnations*—Through every stage of their growth these beautiful flowers have their enemies, from the time of potting out till the period of planting again arrives. We have in successive Calendars noticed these depredators, and endeavoured to point out, as far as our experience went, the best way of destroying or guarding against them No season that we recollect has been more prolific in those "insidious gentry" styled earwigs, or what the north-country folks provincially call "battle-twigs," nor did we ever know them to have been more troublesome, getting into the calyx of the flower, and eating off the petals, to the florist's utter dismay and mortification. Many plans are adopted to entrap them; amongst the most simple and efficacious are dry Bean-stalks laid across the pot, in which they retreat during the day, or small pots filled with moss placed on the top of the sticks; these must be examined every morning Still we are not sure that these are effectual preventives, as most certain it is that these insects can fly Get on with layering as quick as possible, and when pods are swelling extract the decaying petals.—*J. F W*

IV.—PINERIES, VINERIES, &c

Pineries—Attend well to keeping the bottom heat regular, and to the re potting of such plants as require it, in order that the plants may receive no interruption in their growth Should the weather prove stormy (as it now is with us) the linings of pits heated by means of dung alone, will require strict attention Let all suckers worth saving be stuck into the tan, or potted immediately after they are taken from the parent plants, as they suffer much at this season by being allowed to lay exposed to the air Planted in the tan in front of any of the pits, having a bottom heat of about 90°, they soon become well-rooted plants, fit for 6 or 8 inch pots

Vineries—In the houses bearing crops of Grapes for winter use, the surface of the border should not be made wet after the middle of August, and if water at the root is at all required, it should now be given, and after this let the surface become quite dry, so that no vapour may arise from it to injure the Grapes during the dull weather that we may expect before the fruit is all cut. The Hamburgh, Chasselas, and Sweet water Grapes will ripen without any heat but that of the sun Muscats in dull weather will be benefited by slightly heating the pipes or flues.

Peach Houses.—If the lights have not been taken off the early forced Peach-house, it should be done as soon as possible, that the trees may have the benefit of the free air, rain, and dews; all of which will not only assist to feed and perfect the buds for the following season, but also to keep them from the attacks of red spider, which at this time is difficult to keep down under glass. For the management of the late houses, see last week's Calendar.

Figs—Figs are much better flavoured when ripened in an atmosphere not too moist and warm, and with a free circulation of air Keep the red spider in check, or you will have no good fruit in the autumn.

Melons.—Continue to stop and thin the shoots of the Melon plants, supply them with water when necessary, and use every means to keep down red spider and thrips.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Fruit trees—Attend to the removing the broad-wood of Apples, Pears, Cherries, and Plums; shortening the leading shoots and cutting back to a couple of inches the side-shoots of Currants and Gooseberries (unless when the latter are made to bear almost exclusively on young wood), and thinning and shortening the shoots of Apricots and Peaches, as previously recommended. Cover with mats, or thin cloth where practicable, those Cherries, Gooseberries, and Currants that you wish to preserve as late as possible, and defend the remainder from birds by netting. This is a much more pleasant method than making the vain attempt to exterminate the feathered tribe, which, to say the least of it, is very questionable for its propriety, so far as utility is concerned It is only during the short interval that blackbirds, thrushes, &c interfere with our gooseberries, and for a little speculation now they amply repay us, by the quantity of slugs, &c. which they devour in spring, to say nothing of their cheerful notes at "early morn and dewy eve." Considerable interference has been proclaimed here upon a group of starlings that build their nests for successive years in the same trees. I am not aware that the starling ever interferes with our cultivations, but the [illegible] of insects to gardeners which he destroys, for the [illegible] of his young, is truly astonishing.

Green Manure.—The severest summer I have ever gone through in summer the plot of winter Cabbage which is just attained the height of two or three feet, and planted the ruins with Brussels Sprouts, Scotch Kale, and Cabbage, for the early supply, and the vigour with which they have grown convinces me that such a method might be adopted with great advantage, where manure was scarce and ground plentiful. *Onions*.—Preparations should now be made for sowing thickly the Strasburgh, or any other hardy sort, to stand over the winter and furnish large Onions early next summer. Part of them may be drawn for Salads during winter, and the other thinnings planted out in March. Sow again in a fortnight. Ground previously occupied with early Cauliflower, or Strawberries that require digging *down*, will furnish good situations.—*Peas*.—Make the last sowing, choosing the earlier varieties. Prince Albert is the earliest I have met with by eight or ten days, but otherwise it is a small Pea, and produces sparingly. The early *May* is highly spoken of as being as early as the Albert, of a good size, and producing plentifully. *French Beans*—Sow in a situation where it will be suitable to defend them from early autumn frosts with mats, choosing the dwarfest sorts, such as the Early Dew, and the Robin egg China. *Routine*.—See former Calendars.—*R F*

VII.—COTTAGERS' GARDENS.

Proceed with the thinning of Grapes, as recommended last week, and be careful in handling the bunches to twist the stems as little as possible, for fear of injuring them, and thereby preventing the fruit from swelling. Pelargoniums, which were directed to be placed out of doors, should now be cut down, and cuttings of the best sorts prepared and inserted in small 60 sized pots, in a mixture of loam, leaf mould, and sand They should be placed in a shady situation until they have struck root, when they may be more exposed to the sun. After the old plants have made young shoots about an inch long, proceed to re pot them into pots one or two sizes smaller than those in which they are; shake the old soil from their roots, which should be pruned in to within 3 inches of the stem; and give them a good drainage, which is very essential to their future welfare. The plants should afterwards be placed where they will be partially shaded, receiving a little of the morning sun only In a short time they will have formed new roots, and may be removed to a more open situation, where they may remain until the weather becomes cold, when they should be removed under cover Calceolarias and Cinerarias, if not already done, should now have their roots divided they may be planted in shady places in the flower-borders, to be taken up and repotted about six weeks hence; or they may be put into small pots, to be shifted as they require it, which will not be for some time A small bed of Endive, if not already done, may be sown Go over Cucumbers occasionally, to stop and regulate the shoots. Attend to getting up Onions, Shallots, Garlic, &c, that have arrived at maturity, for if left too long in the ground they often make a second growth, which spoils them for keeping —*J M H.*

State of the Weather near London for the week ending Aug 1, 1844, as observed at the Horticultural Garden, Chiswick

July		Moon's Age	Barometer Max	Barometer Min	Thermometer Max	Thermometer Min	Thermometer Mean	Wind	Rain

Notices to Correspondents.

Asphalte—*J W*—This material is light, and will last a long time if kept painted. It makes good garden screens, when nailed to wooden frames But it is not a strong fabric, and therefore cannot be employed where strength is wanted.

Books.—*G Walker*—"Hooker's British Flora," last edition

——*A Subscriber*—"Bevan on the Honey-Bee"

Bromamasia floribunda—*P P*—You keep your plant too cool and too dry. It wants a damp stove, where Orchidaceæ are grown, and there it should be tied to a block of wood, and treated like an epaphyte

Cucumbers—*Anon*—Where bees and other insects have free access to your Cucumber plants, there is no need to impregnate them artificially, but it is better to make success certain by doing so

Flower gardens—*J M*—If you can furnish any practical information upon the management of flower-beds in dry, hot weather, we shall be happy to receive it. We cannot perceive anything beyond "talk" in the note before us

Ice houses—We have to thank several correspondents for the readiness in pointing out a description of an American Ice-house in Cobbett's "Cottage Economy" We propose shortly to extract it for the benefit of ice-loving people.

Insects—*W W W*—Your larva had eaten a hole in the paper and escaped it ought to have been inclosed in a quill. *R.*——*A P*—Your Cucumber (?) plants are infested by Aphides, which will be best eradicated by fumigation with tobacco. *R*——*H W B*—The caterpillars eating your Potato haulm, &c, are the offspring of Noctua (Agrotis) exclamationis, and *R W*'s caterpillars destroying the Mangold Wurzel will change to a moth called Agrotis segetum. The history and figures of the above were published in the 4th vol. of the Royal Agricultural Journal, where the best means of freeing land of these destructive animals was discussed, *but* turning in ducks and hand picking are the surest remedies. No. 1 is Tortrix fulvana; 2, Noctua orbona. *R.*——*W. C. P.*—Mr. Curtis will feel obliged by the Caterpillar being sent to 15, Robert-street, Hampstead-road.

Local Societies.—A Cheshire correspondent asks if we consider it fair to appoint as judges the same two individuals at nearly Exhibition, from the formation of a society; and those individuals nursery foremen in the immediate neighbourhood, who at the last Exhibition, were walking to and fro in the tent while the gardeners were staging the plants, &c. There can be only one opinion on the subject It is most improper for the judges to hold any communication with the exhibitors, and it is very unwise to appoint nurserymen or their foremen in judges. Not that they are unqualified, but because experience shows that people are apt to suspect them of favouring their employers; and although such an imputation may be, and often [illegible] is, unfounded, yet no well-managed society will [illegible] to the feelings of exhibitors on so tender a point. Indeed, we wonder that any nurseryman should like to be placed in the position of a judge.

Manure.—*Anon*—The burning of fruits is generally owing to irregularities in the flow of sap; when the latter is suddenly and unexpectedly urged by much heat and moisture, beyond the rate at which it had been [illegible] moving, such fruits as have thin skins, and little [illegible] comparatively with their weight, as in the case with Persian Melons, are apt to be affected by the vicissitude. In order to prevent the cracking of Persian Melons, Mr. Knight elevated the further extremity of the fruit as much as 30 degrees above the footstalk, and the same plan has been successfully adopted by others.§

Names of Fruits.—*J. L.*—Your Plum is the Myrobalan, or Cherry Plum.‖

Names of Plants—*A. R. C.*—Asclepias obtusifolia; Sedum oppositifolium.——*A K.*—Carex hirsuta.§

Pelargoniums.—*J Matthews*.—Procure the following sorts—Matilda, Garth's Witch, Foster's Sir R. Peel, Duke of Cornwall, Brenham, Oberon, Falchelium, Queen Phillippa, Wizard, Cyrus superb, Garth's Constellation, and Symmetry.*

Picotees.—*C. H. H.*—Vulmer's Princess Royal, Wilson's Picperfect, Wildman's Isabella, Sharp's Wellington, Jessop's Sir W. Middleton, John's Prince Albert, Dickson's Trip to Cambridge, Ely's Grace Darling, Brinklow's Purple Perfection, Barnard's Mrs. Barnard, Gun's Queen Victoria, and Kirtland's Princess Royal *

Pine-apples.—*Pyrenees*.—We are making inquiries. We believe that the fruit in question was never intended by the grower for exhibition, and if so it is hardly a fit subject for comment We will, however, keep your letter by us.

Rhubarb Wine.—*Rhubarb*.—We really cannot advise you to make anything so unwholesome as Rhubarb wine. If you will not be wise, then you should proceed with the stalks exactly as if you were making green Gooseberry wine. Some makers of British wines prepare Champagne from Rhubarb stalks, and abominable stuff it is.

Roses—*R. W*—There is no danger in removing Roses having a dormant bud inserted about this time. If the Rose shoots freely the dormant bud will do the same, provided it is safely united to the stock. Where buds fail other buds may be inserted on the same branch, and near the same place, but below the old wound

Seedsmen—*J B*—We really cannot interfere in little disputes between seedsmen and their customers. If we did, our columns would be filled with letters on such subjects Your remedy is not to deal again with the persons you mention.

Strawberries—*Inquirer*.—We have not an idea what has cut off your Elton Pine Strawberries, while green, close to the calyx

Trees—*A Subscriber*—Wood certainly lengthens after being formed; and therefore it is to be supposed that the stem of a forest-tree may increase in length so as to cause any given side-branch to be at a greater distance from the ground each year. We are, however, not aware of any exact observations on the subject

Wasps.—*W. W P*—We know of no means of banishing Wasps, but their nests are easily killed by pouring into them a little oil of turpentine, in the evening, when they have gone to rest, closing over the entrance to the nest with a clod of earth, pressed firm with the heel.

Whitney's Composition—Various correspondents allege that this renders Calico rotten. The following, from *J. G. H.*, may be taken as a sample of the remainder "About four months ago I applied the prescribed quantity of Whitney's Composition to glazed calico—4*d* per yard—stretched on two lights of a Cucumber-frame; for a time it appeared to answer very well, notwithstanding several showers However, about a month ago I accidentally tore one of the lights, and on examining the rent found that the whole of the calico was quite rotten—in fact become mere tinder. If you, or any of your correspondents can tell me whether the calico or the composition is in fault I shall be grateful, as I am about to erect a greenhouse with a stouter material." Perhaps Mr. Whitney or some one else can throw some light on the subject——*E. J. W*—It is out of our province to interfere with respect to short quantities The deficient bottles should have been returned to the seller. Your letter lies at our office

Miscellaneous—*A*—Treat your Pelargoniums all alike. Rose pruning will appear in the articles on the Rose garden.——*North Earle*.—If you will study the articles on Morphology, now almost brought to a close, you will have no difficulty in understanding why your Rose produces a branch in the middle We cannot name the variety.——*W. D*—A plant of Cattleya crispa, which is throwing up a spike of flowers, consisting of six buds, is a fine specimen, but we have seen as fine It is a free bloomer.——*Crassula cocinea* had better be placed out in a warm border against a south wall, until the cold weather comes, and it will probably bloom next season ?

SEEDLING FLOWERS.

Anagallis—*G F*—When flowers are crushed to pieces in letters their qualities cannot be determined. We see nothing in what remains of your seedling to make it worth distinguishing from its parent.

Carnations—*E. Derby*—Your seedling Rose flake is a flower of good form and substance, the petals are of a good shape, but several of them, and especially the guard petals, want smoothness, being too serrated on the edge; the colour is high and fine, and the flake bold and full, and the white is tolerably good; this flower had been too much pulled about, and some of the guard petals taken out. The colour, form, and substance of the flower are fine *

Fuchsias.—*C. D M*.—The tube and sepals of your seedling No 2 are carmine, and the corolla a blood-colour; hence arises that want of contrast pointed out in our late notice; and the greater proportion of the seedlings lately raised have this fault, and too much resemble each other. Your seedling is a large flower, of good form, but it resembles too much varieties in cultivation, and many others that have come under our observation. *Self* Fuchsias are not now worth keeping, unless of very extraordinary merit.*

Pansies.—*A N. M*—It is impossible to judge satisfactorily of your seedling, in the dried state in which it reached us; the colour and marking is similar to many that we have, and it appears to be very small. These flowers require to be packed in something damp *

Pelargoniums—*A Berkshire Subscriber*.—Your seedling is common in colour, and the form is not very good, the under petals being too long *

Phlox—*W P*.—Your seedling is similar to a variety noticed last week, excepting that your flower is more delicately striped, while the one sent by *J. G. H.* was slightly striped and much spotted. Your seedling will be very ornamental as a border variety, if its marking is constant, which we doubt.*

Picotees.—*R. H M*—The opinion expressed in a former Number is but little altered from seeing your flowers a second time. The bloom of Bachmeister was much larger and finer than the first sent, and our favourable opinion of that variety is increased; but as regards the other flowers our opinion remains the same.*

Pinks.—*J. B. H.*—Your Pink was too far gone to judge of, but the petals appear to be too small, and the edge too serrated for a good flower; the colour is pretty.*

*** As usual, many communications have been received too late

SEED-WHEAT.—Any one desirous of procuring Seed for next year is invited to inspect the undressed Crop of Wheat, SMEATON'S MORETON'S and MORETON'S RED STRAW WHITE, the Acres of which are now standing on WHITFIELD FARM, THORNBURY, GLOUCESTERSHIRE.

The present is the only season of the year when the value of any variety of Wheat as Seed can be discriminated by inspection; for, if the examination of a mere sample of the grain, which can be done at any time, be nearly unintelligible as to its quality in the eye of the baker (see *Ag. Gazette*, No. 9), it is entirely so as to the productiveness or habit of growth of the variety to which it belongs. These points, which are of the highest importance in the eye of the Farmer, can be ascertained only by an examination of the growing plant when in full ear.

JOHN MORGAN, Whitfield, Thornbury.

The Agricultural Gazette.

SATURDAY, AUG. 3, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Aug. 7 } Agricultural Soc'y of England
Thursday, Aug. 8 } Agricultural Imp. Soc of Ireland.
Wednesday, Aug. 7 } Meetings of the Highland Agricultural
Thursday, Aug. 8 } Society at Glasgow
Friday, Aug. 9 }

Wednesday, Aug. 14 Agricultural Society of England
Wednesday, Aug. 14 } Meeting at Dublin of the Agricultural
Thursday, Aug. 15 } Imp. Soc of Ireland.

On agricultural subjects, many of which involve interests of such magnitude—where erroneous ideas, when developed in practice, will cause loss, and perhaps ruin—it is of great importance that the terms used in demonstrating opinion, or in communicating experience, should be perfectly understood.

This remark is intended especially to apply to the use of one word often met with in works on drainage, which has certainly a tendency to mislead, and to which we are inclined to attribute much erroneous and uneconomical practice. We often hear of drains *drawing* the water from the soil—of deep drains *drawing* the water from a greater distance than shallow ones. The natural consequence, we think, in the mind of any one in the habit of hearing this word thus applied, is the entertainment of an idea, which first notions on such a subject would probably favour, that a large drain would be more powerfully attractive of any superabundance of water in the soil than a small one. And we are disposed to attribute much of the useless expenditure in the thorough drainage of land by tiles of large size, which is frequently to be met with, to some such idea as this, thus originated. Draining-tiles of a much smaller size than has hitherto been common, are now generally used: experience has ascertained their efficiency.

The fact of the matter is, that, excepting the maximum limit which it places on the flow of water from land—a limit which, in practice, is rarely if ever in action—the size of drains—we mean their sectional area—has nothing to do with their efficiency. When a drain is completed and exists as an inclined tube some 30 inches under ground, to the interior of which water can readily obtain access, the first consequence is that the water in the soil around this tube oozes into it, and whether this drying of the clay, if it be a stiff subsoil, produces cracks, as Mr. Smith contends, or not, it must evidently create a porosity in the neighbourhood of the drain, which did not before exist. The superabundant water in the subsoil near this porous part, thus falls or trickles through it into the drain, and the earth to which it was attached, in its turn losing its impervious character, becomes a vehicle for the passage of water from a still farther distant part of the subsoil.

When drains have once got fully into action, the process of drainage, which commences immediately after rain has fallen in greater quantity than is required simply to *moisten* the earth, is as follows:—Each addition to the water already present in the soil not being attracted by the already moistened earth, trickles or drops downwards wherever there is a way for it, from particle to particle, and unless a previous drought has extended deeper, as soon as it reaches the level of the drain, whether it be in the middle between two drains, or at the very side of one, there it will stop. The idea is obviously absurd that drains can afford an opportunity for water escaping from any part of the subsoil which is below them. And it is equally impossible to suppose that when they are once in full action, stagnant water will be found in any part of the subsoil much above their level in land which has not been artificially puddled in any way; for, supposing the water whose course we are tracing to have fallen in the very centre between two drains, as far from them as possible, yet as soon as so much more should come as would raise it above the level of the neighbouring subsoil, which was dry, it would trickle away to one side, and so ultimately reach the drain. Given, the porosity of a medium of any kind, and the degree of its molecular attraction for water, to find the least angle of a plane down which water would trickle through it, is a problem capable of solution, and it is upon the data of such a problem that the efficiency of drains, though dug at wide intervals, depends. If, in the case of drains 3 feet deep, water, being stagnant at 2 feet below the surface over the drain, is, in consequence of the angle of inclination of that plane to which we are alluding, to be found 18 inches only below the surface at a distance of 12 feet from the drain, the efficiency of the drain would cease at a distance of 24 feet from it; for supposing the character of the soil to remain the same, water would at that distance be found stagnant within 6 inches of the surface: it would in fact be stagnant in the active soil.

It is on this principle that the greater efficiency of deep drains is explained, for in their case this same plane of inclination, down which water will consent to trickle through such a medium, commencing as it would at a lower level, would extend a greater distance on either side, before coming so near the surface as to be injurious.

On the use of the subsoil plough as a means of diminishing the angle of inclination of this plane, and so increasing the efficiency of drains, we shall speak hereafter. Our remarks at present are confined to an exposition of the inaccuracy and injurious tendency of the terms often used in explaining the efficiency of drains. Drains do not *draw* or attract water. They simply receive that which naturally trickles down to them. If of size sufficient to carry it off as fast as it arrives, well—if of greater size than sufficient so to act, an unnecessary expense has evidently been incurred in making them so large—if of a size insufficient thus to act, they will take as much as they can, the rest accumulating in the soil till a drier season, when it will be ultimately removed; but the injury done by this accumulation of stagnant water for so long a time, will soon prove that the policy of the proprietor, or whoever it was that had this inefficient but cheap drainage executed, though it may have been penny-wise, was pound foolish.

THE CHANNEL ISLANDS.

[THE following observations were made by Colonel Le Couteur, on this subject, at the great dinner of the English Agricultural Society at Southampton.]

The islanders are either farmers, sailors, or soldiers. Enjoying a delightful climate, a rich soil, an inexhaustible supply of manure from their rock-bound shore; blessed with mild laws, liberty of the subject, a free press, an extended commerce—privileges which Englishmen dearly cherish—the people have attained a degree of wealth and contentment almost unequalled.

These advantages have not been unworthily gained. Descendants of that ancient Norman race who visited England with William the Conqueror, they have ever since continued connected with the Crown of England. King John granted them a jury and their charter some years previous to signing Magna Charta. On eleven occasions they have successfully resisted invasions from France, and on every such occasion the Sovereigns of England have granted them some new privilege.

Among other institutions connected with these islands, an Agricultural Society has been of great benefit. It has been formed on the same basis as this Society, viz., on a total exclusion of all politics from its meetings and proceedings; and a like result has attended its progress—entire harmony among its members, and a friendly rivalry for good.

The improvement of Wheat for seed, and the general cultivation of crops, have been among the objects of its attention; but the chief one has been to improve the admirable breed of cattle—admirable for the production of large quantities of rich and yellow butter. The chief defect was in the falling off of the hind-quarters; it has taken nine years of close attention to remedy this defect, and as I have personally kept a record of its progress of improvement, I would urge upon young farmers who seek to improve their stock, not to expect success in less than such a period; at the same time, roundness of barrel, a better handling, and a tendency to fatten, when dried off from milk, were points which had been gained without injury to the milking qualities. The cream of the cows of the Channel Islands was so rich and yellow, that in dairy farms where creamer's milk is sold, one such good cow to every three or four ordinary English cows, would be found useful to impart richness to the cream or butter.

With reference to the highly-instructive and interesting speech of Doctor Buckland on Wednesday, Colonel Le Couteur said, the learned Professor seemed to think that a considerable part, if not all the value of guano, evaporated in one season. He was intrusted, two years since, by the Agricultural Society of Jersey, to carry out some experiments with guano—that season was equally dry with this one—and the effects of this manure was imperceptible on either Wheat, Barley, or Grass; but this year the crop of Grass where the guano had been placed, was so rich and succulent, that the scythe could scarcely be drawn through it. Hence it would appear that it may not be quite so evanescent as is supposed; and it is useful in dry weather diluted with water, and thus applied to plants. Its effects will be found surprising in field or garden.

REMARKS ON DRAINAGE.

I CAN hardly divest myself of the idea that you must have been quizzing the Debenham Farmer's Club when you published the report of their meeting of 28th June last, as it is hardly conceivable that men who have evinced so much anxiety for improvement as to have instituted a club for discussing agricultural improvements, should, after all that has been said and written on the subject, talk seriously about making drains with straw; indeed, the whole report is so extraordinary as to court remark. In the first place, all the speakers agreed that the drains should run obliquely across the field. *Now this*, as a general proposition, has been shown to be perfectly erroneous. Vide Stephens' "Book of the Farm," pp. 537 to 542; Thomson, in "Prize Essays of the Highland and Agricultural Society," vol. xiii. p 295; and Smith's (Deanston) "Remarks on Thorough Draining," p. 9, where he says—"Drains drawn across a steep cut the strata or layers of subsoil transversely, and as the stratification generally lies in sheets at an angle to the surface, the water passing in or between the strata, immediately below the bottom of one drain, nearly comes to the surface before reaching the next lower drain. But as water seeks the lowest level in all directions, if the strata be cut longitudinally by a drain directed down the steep, the bottom of which cuts each stratum at the same distance from the surface, the water will flow into the drain at the intersecting point of each sheet or layer on a level with the bottom of the drain, leaving one uniform depth of dry soil." It would have been fortunate if the speakers at the Debenham Farmers' Club had stated their reasons for preferring the oblique direction, which is so much at variance with what may now be termed an axiom in thorough-draining. In the second place, with regard to filling the drains with straw, a material of such a very perishable nature must certainly be very improper for filling drains where every requisite for its speedy decomposition exists; let us hear what an eminent agricultural writer says on this subject. "It could," says he, "only be dire necessity that would induce any man to fill drains with straw twisted into ropes;" and again—"Only conceive what a mess such a drain must be that is filled up to the height of 8 or 10 inches either with brushwood stripped of the leaves—Oak, Ash, or Willow twigs being the best—and covered with long Wheat-straw twisted into bands."—*Book of the Farm*, vol. i, p. 607. Now, although I agree most cordially with the resolution that the landlords ought to furnish the tiles, and am satisfied that landlords who are fully alive to their own interests ought not only to do so, but see that the drains are executed in a permanent and substantial manner; still, if it can be shown that tile drains can be put in for nearly the same price as those of straw, there will be no excuse for the tenant (even if his landlord objects to assist him when asked) using the latter. Making an approximate calculation then, say that there are 68 roods of drains (6 yards to the rood) in an imperial acre, when 28 feet apart, the cutting and filling for the straw drain must cost at least 1*d.* per rood more than for tile, as the former requires to be deeper, and the filling is much more difficult and troublesome (see report in question); the straw required cannot be less than 2 imperial stones per rood, perhaps more, which, at the price of 2*d.* per imperial stone, or 26*s.* 8*d.* per ton, will make the account stand thus —

	£	s.	d.
Cutting and filling 68 roods drains, at 4*d.*		1	2
136 stones straw, at 2*d*		1	2
If twisted, the expense must be added—	£2	5	4
	s.	d.	
Cutting and filling 68 roods drains, at 3*d.*	17	0	
980, 15 inch tiles, at 20*s* per 1000	19	7	
980, 15 inch soles, at 10*s* ,,	9	9½	
8 stones straw, at 2*d*	1	4	
	2	7	8½
Leaving in favour of straw per acre only—	£0	2	4½

But I believe Ethridge's drain-pipes can be had much cheaper than 30*s.* per 1000, which would turn the balance in favour of tiles. Both of the estimates are exclusive of carriage, which would, no doubt, be greatest in the case of tiles; but as there are seasons when horses are comparatively idle on most farms, they might be employed at a trifling expense drawing the tiles (which, after all, are only three single horse-loads per acre) to a convenient place near to where they are to be used.

The most absurd part of the whole report is one individual gravely stating that he uses "plashings of ditches and borders," *i. e.* brambles and weeds, to fill the drains. Fancy a man growing weeds to such an amount on the borders of his fields as to thorough-drain his farm with them! What is the Royal Agricultural Society of England about? Where is Debenham? It was fortunate that the true interpretation of "plashings" happened to occur to me, or it might have been mistaken for the mud taken out of the ditches in cleaning them.—*John Girdwood, Featherhall, Mid-Lothian.*

ON THE FAILURE OF THE RED CLOVER CROP.

THE Red Clover in this village has failed this year to a very remarkable extent. The fact had attracted my attention, and upon inquiry I find the farmers at a loss to account satisfactorily for the circumstance. Some say it is owing to grubs, or insects, which have destroyed the plant, some suppose the land has become tired (as they express it) of growing Clover. They think our land here (which is the bed called blue-drift, by geologists) requires generally a longer rest than eight years, which is the more usual period that elapses before introducing this crop again in the regular four-course shift. All seem to agree that Red Clover is now-a-days much more liable to fail than it used to be some 10 or 20 years ago. The matter is really very serious; and the fact appears to me so curious, in a physiological point of view, that I shall invite a little co-operation from different quarters, in hopes that we may see whether we can ascertain the real cause to which the mischief may be ascribed. How

I wish some practical farmer of the agricultural body could have been found, rather, more scientifically qualified in the judgment of those eminent men of science, whose names I paraded last year as approvers of experimental co-operation on an extensive plan? This question of the failure in the Clover-crop is one of the infinite number that might be follow up by an organised band of experimentalists, who would probably settle it in a shorter period by some years, than may possibly elapse before it shall have been satisfactorily determined.

I shall venture to set before the readers of the *Agricultural Gazette* an account of a very restricted inquiry which I have been making into the circumstances under which the Clover has been usually cultivated in this parish. I shall even be bold enough to hazard a *conjecture* on the cause to which the *frequent* failure of this crop may be ascribed; and then I shall suggest a very simple method of experimenting, by which persons who may think this conjecture worth testing can assist in confirming or refuting it. In order to condense within a narrow compass a review of the various treatment to which *seven* different fields have been subjected by one or other of *four* of our farmers, I shall present their own accounts, under a tabular form. The abbreviations made use of consist merely of the first letter or two of the words signified. As the objects under culture, and their introduction in the rotation, is perfectly familiar to all practical men, they will have no difficulty in comprehending the table at a glance of the eye. It represents the modifications of the four-course system in the seven field A, B, C, &c. Wheat and Barley are the staple crop, which return in regular rotation every four years; the subordinate crops vary. The figures 1 and 2 placed against each year represent the first and second half of the year. The following abbreviations are employed:—

Ba. Barley.	Ta Tares	d. drained	
Be. Beans.	Tr. Trefoil	f. fed.

In all cases the Clover was looking remarkably fine at the time when the Barley was cut, and (except on G) it began to go off, generally about October, and has continued dying till now, July 27th. The following observations were made on the different fields:—

A. The Clover began to die in patches in October, on that half of the field which had been manured, until it has become nearly bare. The portion of the field which received no manure is looking very fairly, with scarcely any patches of failure, except a large one where the headin had been collected for the purposes of draining.

B. The failure not so complete as in A.

C. The Clover was most luxuriant, and some had even seeded when the Barley was cut. It began to die away in three days afterwards, and was soon so unpromising, that it was ploughed up.

D. Rooks appeared to settle on certain parts of the field before it had been observed that the Clover was dying, and it was supposed that they were attracted by grubs. The owner of this field had other Clover on lands which had not grown Tares. Some of these fields failed, and others did not.

E. The Clover here has nearly all perished, except one line across the field, which, on inquiry, I found was directly over a main drain.

F. The Clover on that part of the field which had grown the Mangold, was on the whole better than on that part which had grown the Turnips; and the crop thought better than on E.

The success in this field was attributed to the superiority of the land. A field near it belonging to another farmer had a beautiful crop of Clover on it; and there I was told the Barley had been sown *very early* in 1843.

The mode in which the failure at first shows itself, is by the Clover withering in small patches, in various parts of the field. This may begin within three days, or not until one, two, or even six months after the Barley has been cut. The withered patches gradually spread during the whole time the Clover is left upon the ground. Some plants appear to recover, but in general the evil continues to increase till nearly all are dead, over considerable spaces of the field. I was shown single individuals of a milk-white maggot in the crown of many of the decaying and dead plants. This will, apparently, be the larva of some beetle. Without pretending to any skill in Entomology, I feel pretty confident that this larva was not the real cause of the mischief. I had rather, however, leave that part of the inquiry to professed Entomologists, contenting myself with the observation that where such a very extensive failure has taken place, it seems hardly likely that a stray field, here and there, should have entirely escaped the ravages of these insects, whilst those in the immediate neighbourhood were suffering so severely. There are circumstances in the case which incline me to suspect that possibly the parent insect lays its eggs only, or chiefly, in those plants which have already shown symptoms of decay. But I speak here with the greatest hesitation.

A favourite theory, which involves a peculiar definition of the word "tired," is the supposition that the land where these failures occur may have been deprived, some eight or ten or more years ago, of a certain hitherto unascertained mineral substance, more especially essential to the healthy development of the Clover crop. Tired, in this sense, does not exactly mean that the land has been overcropped, or too much exhausted, for the general purposes of cultivation; it merely means that a homœopathic dose of this hitherto unknown "something" has been abstracted, and, consequently, that whenever the refinements of chemical research shall have ascertained what this "something" really is, there will be no further dread of the failure of a Clover crop. This "something" will be required in such small proportion, that nothing will be easier than to restore the "tired" earth to its pristine vigour, and fit it for bearing as much Clover as Atlas may feel disposed to allow us to lay upon it. Now, I do not mean flatly to deny the correctness of this favourite theory; but until this unknown "something" shall have been detected, and thus the theory have become firmly established, I shall not hesitate to oppose conjecture to conjecture, and to venture a suggestion, that the frequent failure of our Clover crops may be attributed to a physiological, rather than to a chemical or an entomological cause.

Under what circumstances is Clover usually cultivated? In every instance, so I am assured, it is sown on land which is simultaneously occupied by Barley, or by some other white crop. Therefore, during the early stages of its growth, and up to the time when the white crop is cut, the Clover is not developing under conditions which a nursery gardener, or even a botanical physiologist, would consider to be otherwise than injurious to the constitution of the plant. It is shaded and sheltered by the Barley, too much for the direct light of the sun to have such full influence upon its leaves as may stimulate them to the preparation of a full proportion of the "proper juice" essential to the perfectly healthy condition of the plant. I find the Barley-stubble is sometimes left lengthy, in order to nurse the Clover, *i. e.*, to protect it from the evils consequent on a too sudden exposure to a harder condition of life than that to which it had previously been accustomed. Experience, no doubt, has suggested the propriety of this step; but that very experience points to the primary cause (as I conjecture) of the frequent failures in this crop. The Clover has been living under a vicious system of education, and when the protection of the fostering Barley is removed, finds itself (like some over-fondled youth when he gets to Cambridge) unequal to cope with a world of evil influences to which it is now so suddenly exposed. After the Barley has been cut, there may be a variety of circumstances, more or less contributing on the one hand to restore it to a healthy state, or more or less conducing, on the other, to increase the debility of its weakened constitution, and ultimately to bring it to an untimely end. Very slight differences in the soils of different fields, or even in different parts of the same field, may have most marked effects upon plants thus circumstanced. Local differences in the Barley crop may also be among the inducing causes to a variety of results. Variations in season must be ranked among the causes which are likely to operate advantageously, or otherwise, upon Clovers growing on different soils. Another consideration presents itself to my mind, upon a review of the circumstances under which I am told those Clovers are pretty generally cultivated which are expressly intended for seed. They are either fed off in May or else they are then cut, in order that the seed may be produced from fresh shoots; experience having proved that the "virgin seed," as it is called, obtained from the first shoots, is worthless. That seed procured from plants cultivated under circumstances so disadvantageous to the formation of an adequate supply of "proper juice" should be worthless, will not appear at all wonderful to botanical physiologists. Their theory of vegetable nutrition may readily incline them also to admit, that the seed may be good which is obtained from the fresh shoots, supplied as they now will be by proper juice, which has been elaborated under somewhat improved conditions, and also concentrated, as it were (by this destruction of the first shoots), for the use of those stems which themselves are now developing their leaves under the very best conditions required for the vigorous health of the Clover. But although the seed thus obtained may be good, will it be the very best that could be raised? Let this question also be answered by the trial of fair and sufficient experiment. I am inclined to think that seed ripened from plants which may never have been half-choked by the Barley, or afterwards mutilated as late in the year as the month of May, would be more likely to produce a robust stock than seed procured in the usual way. It may possibly have been a work of years gradually to have impressed upon a hardy native stock, like Clover and Trefoil, the more tender constitution of an exotic; just as it may require the pinching of more than one generation of our sturdy peasantry, to reduce them to such dastard degradation as befits only the policy of a despotic sovereign. But peculiar management will in time work wonders in changing natures (vegetable or well as animal) from good to evil, as well as from evil to good.

The day is passed when the agricultural body were unanimous, or very nearly so, in sneering at our sciences, because we asserted we could tell them more about the "laws of nature," and the "reasons for their practices" than they knew themselves. Therefore it is that I now venture once more to direct attention to the propriety of a little co-operation in the attempt to verify a suggestion supplied by a slight acquaintance with the principles of physiological botany. I am not at all trespassing as I did last year, perhaps rather injudiciously, upon the province of the chemist. I now find that I should have spared myself the trouble of inviting the farmers of Suffolk to try our gypsum experiment, if Boussingault had only published his work some 18 months ago. It seems that he has made such advances towards a full determination of the *modus operandi* of gypsum, both *directly* upon leguminose plants, and *indirectly* in the fixation and liberation of ammonia under the forms of two salts useful to vegetation, that my little humble experiment is not very likely to be of much service in the cause; still it will be a pity not to carry it out fairly, now that it is so much advanced—and even yet it may possibly not be without its uses.

The inquiry I now suggest is, whether the Clover of 1844 may not be a more tender stock than is advisable for the description of culture to which it is subjected by our farmers; and whether we can contrive, by growing seed apart from those crops which are intended for fodder, to produce a better race of plant? Let those who sow Clover next spring leave a stetch or two in the middle of their fields, without any intermixture of Barley or anything else. They will thus have an opportunity of seeing whether such unsheltered Clover behaves itself like the rest, and whether the seed it shall produce (without the plant having been touched by tooth or scythe) may not the following year give birth to a somewhat sturdier race. If it should ever be proved to the satisfaction of all farmers, that a more careful attention to the seed-crops destined for future culture is an important step in the progress of agriculture, then, perhaps, we may see a suggestion followed out, and which has long been a favourite notion of my own also, that it would be advisable to encourage the labourers of every parish to direct their aim, in a special manner, to the growing of certain crops for seed upon those allotments, which we may hope before long will be more generally provided for them throughout the country.—*J. S. Henslow, Hitcham, July 29, 1844.*

HISTORY AND CULTIVATION OF WHEAT.

There are two sorts of Wheat cultivated in this country—Triticum hybernum, or winter Wheat, and T. æstivum, or spring Wheat.

There are many varieties of both these kinds of Wheat in cultivation. The white sorts are generally esteemed the best—the red varieties having a thicker and rougher husk, a hardier nature, and being better adapted for cold climates; but they are less productive, and yield an inferior flour to the white.

The Spring Wheat is less hardy than the winter variety, and in our uncertain climate is seldom cultivated, except in some of the more southern counties. The grain is smaller and less productive than winter Wheat. The only advantage it possesses is the security which it offers against the injurious effects of a cold and rainy spring; so that in situations where winter Wheat has failed, it can be sown as a substitute. It is the practice of some farmers, when the winter Wheat has gone off in patches, or appears thin, to raise by spring Wheat into the vacant places; by this means, if the operation be performed early enough, the uniformity of the crop is restored, for the spring-sown Wheat will arrive at maturity as soon as the winter-sown.

When spring Wheat is intended to be sown by itself, it should not be delayed beyond the end of March; from which time till its maturity, the farmer has little to dread from severe weather. Sir Humphry Davy, in his valuable work on "Agricultural Chemistry," says the nutritive parts of spring Wheat are not quite equal in quantity to those of winter Wheat, being 95½ per cent. in the latter, and only 94 per cent. in the former, of the entire bulk of the grain: the gluten exists in a greater degree; that of winter Wheat being 26, while spring Wheat is only 19 per cent.

Winter Wheat is generally committed to the ground in October or November in England, on a Clover-ley, with one ploughing, or on stubble-ground summer fallow. The land should be well manured, clean, and well manured; this being accomplished, it is of little import-

ance whether the grain is sown broadcast or in drills; three inches of harrowing is sufficient to cover the seed, the water furrows being drawn immediately; and cuts opened to carry off the surface-water to the ditches at the end of the fields. The soil on which Wheat thrives best in our uncertain climate, is a strong, rich clay. The quantity of seed which is generally sown, varies on most farms according to the quality of the seed and richness of the land. There are many conflicting opinions amongst farmers as regards the depth that the seed should be sown; some are advocates for shallow, and some for deep: in our opinion three or four inches is amply sufficient. The farmers of warmer climates are obliged to irrigate their Wheat lands during the growth of the plant. In the greater part of the temperate regions of New Spain, the farmers are compelled to adopt artificial irrigation. This is done by small canals cut through the farm, and supplied with water from the rivers and reservoirs, which can be let loose over any part or all the farm at one time, in those districts where irrigation is regularly adopted. The produce of the Mexican farms is far beyond what the richest soils of Europe could produce, the Wheat harvest being commonly 35 and 40 seeds, and some of the larger farms yielding 50 and 60 measures for one of seed. When the land is not irrigated, the annual return does not exceed more than 15 or 20 seeds.

The Wheat chiefly cultivated in Egypt and some parts of Italy is the Triticum compositum, Egyptian or many-spiked Wheat. This species is supposed to be indigenous to Africa, its stem are branched, and each bears several spikelets or ears, which are bearded, the grains are thinner and less nutritive than our ordinary varieties. This species endures, without injury, the extremes of heat and moisture, so that it is well adapted to those countries in which it is generally cultivated. Triticum Spelta, or Spelt Wheat, is supposed to have been the species cultivated by the Romans; it is cultivated to a considerable extent in the North of Africa and the Cape of Good Hope; in Spain, where it is given to horses instead of Barley or Oats; in Germany, Switzerland, the South of France, and in some parts of Ireland. There are two varieties of Spelt Wheat, one with awns and the other without them, it is generally sown as a spring crop, and grows luxuriantly; bread made from it is of a dry quality and less nutritive than the ordinary kind In some parts of Switzerland the Triticum monococcum, or one seeded Wheat, is cultivated, this species contains less gluten than the common varieties, and is very diminutive, the spike containing only a single row of grains, it is mostly used in soups and gruels, the straw, from its hardness and tenacity, is well adapted for thatching, for which purpose it is generally used.

We are of opinion that Wheat would flourish better if it were buried deeper than it generally is by most farmers. Our opinion is founded upon the following facts:—A grain of Wheat, when buried to the depth of three inches, undergoes the following transformations —As soon as the farinaceous matter of the seed is softened, a germ is pushed out, and at the bottom of that germ small roots soon appear, these roots gather strength, whilst the germ, fed on the milky fluid of the softened seed, is springing upwards. When this substance is exhausted the roots are in activity, and are collecting food for the young plant from the soil, when the germ has fairly got above the surface of the ground, and becomes a plant, a set of fresh roots are thrown out close to the surface of the ground, which search for food with the same activity as the under ones search the lower parts, and that part of the germ which separates the two sets of roots, now becomes the channel through which the lower roots supply the plant with the food which they have collected. These two distinct sets of roots serve to fix the plant firmly in the soil, and to collect nourishment from every quarter. The upper roots are situated so as to receive all nourishment which comes naturally from the atmosphere, or artificially, as manure to the surface, and serve the important purpose of being the bases of new stems, which are tillered up, and greatly increase the productiveness of the plant.

Wheat that is sowed in autumn, a Clover lea excepted, should, instead of harrowing, be covered with a shallow furrow, and the surface left rough. It will be less in danger of being killed by severe frost in winter, and less injured by drying winds in the following spring. The furrows should be left without harrowing, for the more uneven the ground is, the more the soil will be pulverised and mellowed by the frost. But if the crop which succeeds the Wheat crop should require a smooth bottom, the land, after sowing, must be harrowed, and should be rolled. Some farmers advise, when Wheat is sown on a Clover lea, to plough in the Clover with a deep furrow, then plough in the seed Wheat with a shallow furrow.

In preparing seed Wheat, the first thing to be attended to is to clear it perfectly from every injurious foreign substance; one error here may mar the whole system, and render one skill productive of as much evil as good. On poor and worn-out land, the evil of sowing seeds of weeds with our grain would be great, but when the ground is in high order, the crop is more luxuriant, the noxious plants take firmer hold, and are more difficult to eradicate. Indeed, it would be better for a farmer to make a riddle of his fingers than to sow Cockle, Darnel, Tares, and other vegetable nuisances, which are as tenacious of life as they are unworthy of it; the first preparation, therefore, should be to winnow and riddle the grain perfectly clean. When this is thoroughly accomplished, washing and steeping, for the purpose of preventing smut, should meet attention.

Wheat is exposed to a disease called smut, the real nature and cause of which have hitherto baffled the researches of our most scientific inquirers, and the cure has completely baffled all the attempts of our best agriculturists. It prevails more in wet climates than dry; white Wheat is more affected by it than red; and Wheat sown in spring is not so liable to be diseased as that sown in autumn. Sir J. Sinclair enumerates the following modes by which smut may be prevented:—1, the use of pure cold water and lime, 2, boiling water and lime; 3, water impregnated with salt, 4, urine pickle; 5, ley of wood-ashes, 6, a solution of arsenic; 7, a solution of blue vitriol. Mr. Arthur Young sowed 14 beds with the same Wheat seed, which was black with smut. The first bed was sown with this Wheat without washing, and had 377 smutty kernels. A bed sowed with seed washed in clean water produced 325 do —washed in lime water, 43 do.—washed in ley of wood-ashes, 31 do.—steeped in lime-water four hours, 2 do —steeped in ley four hours, 3 do —steeped in arsenic four hours, 1do Again, that which was steeped in ley, as before mentioned, 12 hours, had none; and that which was steeped in the same kind of ley 24 hours, had none, that also which was steeped 24 hours in lime water, had none; that steeped in arsenic 24 hours, had 5.

Wheat is subject to another disease, called rust or mildew. Common Wheat is more subject to this disease than bearded Wheat, especially if the land has been newly manured with too great a quantity of fresh dung, it generally commences in July, at the time of the filling of the kernel in the ear The remedies against it, according to Sir J. Sinclair, are as follows:—1, Cultivating hardy sorts of Wheat, 2, early sowing; 3, raising early varieties; 4, thick sowing, 5, changes of seed, 6, consolidating the soil, 7, using saline manures, 8, improving the course of crops, 9, extirpating all plants that are receptacles of rust, 10, protecting the Wheat-plants by Rye, Tares, and other crops. The above remedies are enlarged upon by Sir J. Sinclair in "The Code of Agriculture," but his observations are too voluminous to quote here If a field be evidently affected with rust, and the progress of vegetation stopped, the only way to preserve the straw and the grain, if any has been formed, from being entirely lost, is to cut it down immediately, even though the crop should not be ripe. The straw is thus preserved, either for food or litter, and it is maintained that any nourishment in the stem will pass into and feed the grain and make a greater return than could be expected For a more elaborate account of the diseases of Wheat, we refer our readers to the "Quarterly Journal of Agriculture" for June, 1837.

One of the most destructive insects to which Wheat is exposed is the Corn weevil (Curculio granarius) This insect is a beetle about the eighth of an inch in length, of a blackish-brown colour The female, by means of her long proboscis, perforates a small hole in a grain of Wheat, and in this she deposits a single egg In about a week after being deposited the eggs hatch, and the grubs continue to live inside for some time, devouring meanwhile the farinaceous parts of the grain. When they have fed, and grown to their full size, they transform into a chrysalis inside the husk, which they quit about a fortnight afterwards, when they have transformed into their beetle state Kirby and Spence calculate that a single pair of weevils may produce in one season 6000 descendants

To rid a granary of these destructive insects, it has been recommended to farmers to spread their Corn in the sun, when they will creep out of their holes, and by often stirring the Corn whilst in this situation, it is supposed that they may be completely expelled It is also said that they may be destroyed by strewing boughs of Elder or branches of Henbane among the Corn Some recommend the use of Tobacco, either green or in rolls, as a preventive against weevils, they will come to the Tobacco from all parts, and, having eaten of it, certainly die. And the Rev. F. W. Hope says that it is a common practice in some parts of Spain to expose the Corn to a heat of 150 degrees, or more, for the purpose of destroying these insects.

Ice houses have been recommended to be used as granaries, and there can be but little doubt that, if the grain is surrounded with ice, it would escape the attacks of all insects. If there were any grubs or weevils in the grain when put into these ice granaries, they would die.—*John M'Intosh.* [This idea could, however, be carried into practice in but few climates where Wheat is grown.]

ON THE APPLICATION OF MANURES.

(*Continued from page 511*)

"We know," says Liebig, "that the functions of the leaves and other green parts of plants are to absorb carbonic acid, and with the aid of light and moisture to appropriate its carbon." "The verdant plants of warm climates are very often such as obtain from the soil only a point of attachment, and are not dependent on it for their growth." "Large forests are often found growing on soils absolutely destitute of carbonaceous matter, and the extensive prairies of the western Continent show that the carbon necessary for the sustenance of a plant may be entirely extracted from the atmosphere." Indeed, from the moment the leaves are formed he attributes to them the power of supplying the plant with the requisite nourishment from organic matters, that is, the products of animal and vegetable decomposition. He says, "When a plant is quite matured, and when the organs (the leaves), by which it obtains food from the atmosphere, are formed, the carbonic acid of the soil is no further required." This, however, infers, that till then the carbonic acid of the soil is required; and, indeed, he says, "In spring, when these organs (the leaves) of plants are absent which nature has appointed for the assumption of nourishment from the atmosphere, the component substance of the seeds is exclusively employed in the formation of the roots. Each new radicle fibril which a plant acquires may be regarded as constituting at the same time a mouth, a lung, and a stomach The roots perform the functions of the leaves; from the first moment of their formation they extract from the soil their proper nutriment, namely, carbonic acid generated by the humus." But I do not see that he produces any proof of this, it appears rather a concession to the long-standing prejudice, that plants receive their alimentary juices from the soil alone, in every stage of their existence, giving to the leaves merely an elaborating power governed by a vital principle; this vital principle, however, is discarded by Liebig. Nor can I admit, with Liebig, that even from the first it is necessary that carbon should be extracted from the soil by the roots, for grain will vegetate in distilled water, and with some appearance of contradiction Liebig himself says, "That the component substance of the seeds is exclusively employed in the formation of the roots," and with moisture this component substance of the seeds appears to me to be sufficient. In a report made some few years ago by Drs. Thomson, Hope, and Coventry, to the Excise Board of Scotland, we find it stated, that in malting Barley (for the purpose of making spirits or brewing) about a day after the sprouting of the roots, the rudiments of the future stem may be seen to lengthen. It rises from the same extremity with the root, and advancing within the husk, at last issues from the opposite end of the seed, and assumes (but this is prevented) the form of a blade of Grass. As the plumule shoots along the grain, the appearance of the kernel, or mealy part of the corn, undergoes a considerable change and becomes sweet, (that is, the starch is transformed into sugar). It is the common opinion of maltsters that this change of the grain always keeps pace with the plumule—the young leaf, be it observed—each seed being altered as far as the point of the plumule extends, and no further. It does not appear that a plant ever seeks a supply of nutriment from the soil, it rather appears to avoid the locality where it is to be met with, and to push its roots beyond its influence. If with a very little care we take the earth from a Turnip-plant just attaining its rough leaf, and where manure of the most volatile nature is used, the least likely to descend into the ground—say guano—we shall find the stronger and coarser fibres of the roots have pushed down 5 or 6 inches, the finer fibres might be traced, with greater care, much deeper. It cannot be for a moment supposed that the guano could have penetrated so soon to such a depth, the roots have not them gone in quest of the alimentary juices, which manure could afford The lateral branches of the roots of a tree or plant may stretch for some distance near the surface, and in the parts where the richer vegetable mould exists, induced probably by the moisture generated by decomposing matters, but their ends, the recipient parts of the roots, tend downwards, as do all the fibrils of these root-branches. This has by some been attributed to gravity, but as the stem above the ground exceeds in gravity the root below it, the same rule should hold good with more force to bring it under the soil. If to mere gravitation we are to attribute the descent of some roots, why do not roots subject to the action of running water submit to the same rule, but that they find that which they seek nearer at hand? For the formation of the root, carbon does not appear to have been acquired from any other source than the seed in the malting process of Dr. Thomson, &c Liebig says the roots perform the functions of the leaves, but they are supplied with their nourishment in the first stages of their existence by the seed, and this I would rather say performs the functions of the leaves to them till the leaves are formed; it is the seminal leaf which feeds the root. From the moment the plumule shoots, it provides for itself by the absorption of carbonic acid from the air in the artificial growth (the formation of malt), and from the soil in the natural growth, its power of so doing and its production are simultaneous. We can fix no other period for its acquiring this power, from the moment it shoots it begins to exert this power, and if the root is broken off, by it a new formation is commenced. Drs. Thomson, &c say, "Many of them (the roots) are broken off during the turning of the malt; and, in that case, new roots generally succeed them That all substances in solution in a soil are absorbed by the roots with the water in which they are in solution cannot be denied; but I think the presumption is against organic matters thus presenting themselves The leaves of plants are equally, in all probability, without the power of refusing that which presents itself to them in solution in the gases they take in The leaves and roots of plants may perhaps occasionally perform the functions of each other, as the pores of the skin in an animal may be made inlets of food when it cannot be received by the gullet; but I believe the office of the root is solely to supply the plant with moisture, that of the leaf with those gases which, together with moisture necessary to all chemical action, become the food of plants.—*Lieut. J. M. Goodsir, Revenue Police, Graham, Ireland.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

(THE LAND OCCUPATION, *continued*)

THE ploughing of the stubble land to be green-cropped the following year, commences immediately after the labours of the harvest, and the sowing of Wheat after summer fallow and Beans and Potatoes harvest are concluded. It is

…ason, but unfrequently must it involve the completion of the…sowing, as the state of the weather and other circumstances may render convenient or necessary. The stiffest and wettest fields are thrown ploughed first, for the purpose of allowing the soil to derive the full benefit from its exposure to the effects of frost and other atmospheric changes during winter. Frost, in particular, exercises a very powerful influence in meliorating strong adhesive soils.

The general mode of ploughing stubble land is by casting the ridges in the manner already described. The furrows are now made in the open furrows; those in which furlongs had been previously made becoming open ones. The ridges are thus ploughed in a direction contrary to that in which they had been last done, the furrow-slices being reversed.

Sometimes when the land is very wet and tenacious, the ridges are cloven, furing being made in every furrow. All the furrows are kept clear for the purpose of preserving the land in a dry condition during the winter. Immediately after the ploughing of the ridges is completed, whether the field has been in Grass or in Stubble, the headlands upon which the horses turned are ploughed: they are usually of the same breadth as the ordinary ridges. In many instances a ridge is left unploughed at either side of the field, to be ploughed with the headlands, as one continuous ridge round the field. When this is not done, the headlands are generally cloven when broken up from lea, and gathered when next ploughed from stubble.

It may be proper to observe here, that the system of crown-and-furrow ploughing, although the most expeditious, is generally disapproved of, and is, therefore, but seldom practised in this county. In heavy land which has not been thoroughly drained, and in which a considerable degree of curvature is usually given to the ridges, this method of ploughing is, for obvious reasons, altogether inadmissible. Even in light dry soils crown-and-furrow ploughing has latterly fallen into disuse, because necessarily occasioning as many open furrows as there are ridges—a defect which is obviated, to a great extent, by the practice of casting the ridges.

Cross Ploughing.—In the usual management of the farm, the first operations performed in the spring are the sowing of spring Wheat, Beans, Oats, and Barley; after which the land to be that year in green crops receives a second furrow, beginning with those parts which are intended for Potatoes and Swedish Turnips. This ploughing is sometimes, but not frequently, given in a direction crossing that of the ridges. In dry, friable soils direct cross-ploughing is perhaps to be preferred, as in light, porous land no great danger need be apprehended from wet weather; but where the soil is heavy, and not thoroughly drained, considerable injury is frequently suffered by its being ploughed into large flat ridges crossing the former ones, especially should a long continuance of wet weather ensue. In such circumstances the second furrow is generally given lengthwise, or in the direction of the ridges, especially should the weather happen to be rainy or unsettled at the time. The next ploughing is usually given across; and if any more are rendered necessary from the nature of the crop to be sown, or the condition of the land, they are given in various directions, determined by circumstances. It is injudicious to plough the same land twice consecutively in one direction, if it can be safely avoided. Instead of ploughing directly across the ridges, a diagonal direction is frequently adopted, the inclination to the line of the ridges being regulated by the slope of the field.

The depth to which land is ploughed depends upon the quality of the soil, the nature of the crop, and the operations which are to follow. In ploughing lea, 9 inches wide by 6 in depth are the usual dimensions of the furrow-slice, the common calculation being that the breadth and depth should be nearly in the proportion of three to two. It is deemed injudicious to plough deeper than six inches, or to expose any new soil in ploughing Grass land, particularly old pastures. In giving the first, or winter furrow, to stubble lands, preparatory to green crops, the plough is made to penetrate as deep into the soil as it can be drawn by two horses. From 9 to 12 inches is the usual depth. The first furrow for summer fallow, and for Beans, is generally ploughed something deeper than that for Turnips or other green crops. On well-conducted farms, the stubble land is always ploughed to a considerable depth, in order to expose as much fresh soil as possible—when the subsoil contains nothing noxious to vegetation—to the mellowing influence of the winter's frosts. In the process of preparing the land for green crops, the second, or cross furrow, as it is sometimes termed, is invariably taken as deep as the strength of two horses will accomplish. When it is considered desirable to plough to a greater depth than 12 inches, as in summer fallows, three or four horses, according to the nature of the soil, are yoked together. In the case of such deep ploughing a piece of plate-iron, about 3 inches in height, is sometimes attached to the upper edge of the mould-board, for the purpose of increasing its height, and thereby preventing the earth from falling back into the trench. Shallow-ploughing is invariably practised after Turnips are eaten on the ground by sheep, that the manure may not be buried too deep; and also in covering in lime, because it usually tends to descend of itself into the soil. In ploughing down farm-yard dung—a practice which I have already mentioned as being prevalent on heavy soils in this district—it is not desirable to go only deeper than what is necessary to cover the manure, so that none may be left exposed to the influence of the atmosphere.

The general breadth of ridges is 18 feet, this size being found the most suitable for the several purposes of sowing, harrowing, and reaping. In very dry and light soils, ridges are frequently dispensed with altogether, such land being commonly ploughed into very wide ridges called *flats*, and otherwise marked off into ridges of the ordinary breadth, in order to regulate the sowing and reaping. In some places where the land is of a dry porous nature, ridges are often made 24 and 36 feet wide. There are what are here termed *bout-ein ridges*, in consequence of being reaped by a band commonly of six reapers attended by one binder. The direction of the ridges, owing to the irregularity of the fields, is very various. As the principal ridges or hills, of which the county is composed, lie in a direction from east to west, the land slopes either to the north or to the south and the ridges accordingly are made to lie in the same direction, by which the Corn at both sides enjoys nearly equal advantages from the influence of the sun. Although the direction of due north and south is, for this reason, to be preferred, when the circumstances permit, yet it is the particular inclination or slope of the field that mainly regulates the direction in which to run the ridges. The practice almost universally observed, is to form them directly up the greatest acclivity of the field, by which the land, particularly such as is of a strong retentive character, is preserved in a comparatively dry condition during winter, or in very wet weather. The operation of ploughing strong clayey soils too, can never be so surely, or so effectually performed as when the land is ploughed directly up the acclivity. When the ascent, however, happens to be very steep, the ridges are frequently formed rather diagonally, with a slight inclination towards the right hand at the top. By this arrangement, in ploughing up the acclivity the furrow-slices fall more readily from the plough, which considerably diminishes the labour of the horses. Another advantage resulting from forming ridges in an oblique direction on such land is, that the surface soil is less liable to be washed down from the higher to the lower ground by heavy rains or currents, while in droughty seasons much more moisture is retained.

It may not be improper to mention in this place, that a kind of plough having two coulters and two mould-boards was much used some time ago in East Lothian, for ploughing across steep declivities, in order that the furrow-slices may be always turned down the hill. By means of a very simple contrivance, one coulter and mould-board was depressed, while the others were elevated, at the end of each furrow, by which all the slices were ploughed to one side. Although a plough of this description was much used in such situations so far back as 30 or 40 years ago, neither it, nor any of the improved turn-wrest ploughs since invented by Mr. Smith of Deanston, and others, is now used, it being considered highly injudicious, if it can be possibly avoided, to plough directly across the declivity. An oblique direction is always preferred, because, by adopting the former practice, the soil is worked down to the bottom, where it speedily accumulates, leaving the top bare and unproductive. In speaking of ridges, I have hitherto supposed them as running through the entire length of the field; but as the land frequently slopes in different directions, and as the fields are, generally speaking, of a large size, it is sometimes expedient to alter the course of the ridges, in order to answer the inequalities of the surface, or to diminish their length for the purpose of lessening the labour of the horses. Accordingly, in very large fields of irregular surface, the ridges take various directions, so as always to have them lie with the greatest declivity, unless when the inclination happens to be very abrupt. The quantity of land ploughed in a day by a pair of horses, depends very much upon the quality of the soil, and the dimensions of the furrow-slices. As the land is for the most part very adhesive and difficult to labour, the motion of the horses is necessarily slow, but even in the strongest soils a pair of stout horses is allowed to be capable of completing in nine hours three roods when the land is in Grass, or about an imperial acre when ploughed from stubble. In very light soils, or when the land is in a loose half-pulverised state, considerably more is often done, but in an average quality of land, a statute acre is the general allowance to a pair of horses in the day.—*T. Sullivan.*

Home Correspondence.

Adulteration of Manures.—I collect from your Paper, as well as from other sources, that great adulteration either takes place, or is suspected, in that valuable manure guano. I observe too that a certain class of chemists and country druggists are desirous to have the job of analysing every bag which is bought and sold. I do not wonder at this: they will make a good thing of it, if they can persuade the farmers to come into the plan; but this they never will do, and the sooner you put an end to this wild notion, and recommend something more practicable, the better it will be for all parties. I will suggest to you a certain remedy for the evil. There are several large houses who import great quantities direct from the countries where it is found; they will, of course, always bring the best article they can find, as the charges and expenses are no more upon the good than they are upon the bad. They are highly respectable people, and may be trusted; but besides this, you have their interest on your side, because it is a great object to them that the trade should increase, which can only be by the increase of consumption consequent on the good effects of the manure. They are sure, therefore, not to adulterate it. Now all the farmer has to do is to write an order direct to the merchant who imports, and he will get the guano from the first hand, at the first price; be quite sure there is no adulteration, and save money by not going to the middle-man, where only the adulteration now so universally complained of takes place. The farmer, however, will have to pay the carriage; and in order to reduce that he may recommend to him always to purchase the very best quality imported.—*J. G.* [The plan suggested by our correspondent will be a security in a measure against *artificial* adulteration, but not against that (which, however, is not so much to be dreaded) arising from natural causes—the admixture of earthy matter with the manure by wind, for instance, on the islands where it is procured. It is the interest of those who import nitrate of soda and other salts, as much as it is of the importer of guano, to procure a pure article, for it saves them expense of carriage; but we know that the former article as imported is often adulterated to the extent of 10 or 20 per cent. The purchasers of this, however, are not cheated; they judge of the quality of what they buy from an authenticated analysis. Why may not the purchasers of guano have this security also? We reiterate our advice to all purchasers of guano, to require from all venders of it authenticated analyses in this manner, and then "put aside a pound of the substance in a glass bottle, cork it securely, and seal it up, so that it may eventually become evidence against the seller. If crops fail, or suspicion is aroused, have it formally analysed, and then if it turn out to be different from the analysis on the faith of which it was bought, proceed at law against the seller."]

Hybridising Barley.—I have endeavoured to hybridise Alpine Strawberries with Hautbois, and *vice versâ*, but have never succeeded. I have frequently thought that Hordeum pratense might be hybridised by common Barley, and that the result would be a larger grain in the Hordeum pratense. I apprehend that the first operation would not be attended with perfect results, but think that if the hybridised Hordeum pratense were again and again operated upon, by the third season the object might be attained. But this may perhaps be needless, as I think I have read of a Polish or a Russian sort of Barley that is perennial. I have also thought that if the larger grains of Hordeum pratense were selected, a larger grain might be produced; and that, if the largest of these larger grains were selected, the same sort of result as above might be attained. What, however, I chiefly seek for is a Barley of a hardy description, that might stand the winter, and be harvested earlier in the ensuing season. Perhaps some of your ingenious readers may turn this hint to account.—*M. B, G.*

Bark of Trees.—Your correspondent "Clericus, V.," inquires in last *Chronicle* for "a simple means of preventing cows from gnawing the bark of trees." I have suffered from the havoc made by sheep in this respect, and have found a preparation of soot and cowdung a pretty good preventive, the soot being the active agent; but the appearance is unsightly. I mean to try a strong infusion of Socotrine Aloes as the cheapest bitter I know of, and free from the objection to soot on the score of its colour.—*Anon.*

Late Horse-hoeing.—This is, as you say, an important question. We are told, on good authority, that Raspberries, Strawberries, Vines, and indeed all fruits, should not be dug about at all. Am I right in supposing that the seeming contrariety between this advice and yours about Turnips arises thus?—In the case of Turnips, Potatoes, Cabbages, &c., where a large system of leaves or tubers is wanted, the frequent and late digging is beneficial, inasmuch as it encourages vigour of growth in the plant, both leaves and roots; but in the case of fruits you must check the growth sometime or other, or the plant would not blossom, or, at least, there would be comparatively few blooms.—*W. C.*

Selection of Seed.—As the two following examples may prove useful to some of your readers, by impressing on them the necessity of being very careful in procuring seed for the Turnip-crop, I will transcribe them from my note-book, for insertion in your Paper. Not having quite enough Swede-seed to drill the whole of my field, I procured a small quantity from a country seed-shop to complete the job; but when the plants began to come up there was a remarkable difference in the rows where this seed was used. The plants were not only several days later in making their appearance, but came up very irregularly, and did not grow so fast as the others. The seed drilled in the rest of the field was grown last year by a neighbour, and not beaten out till this spring. They were both drilled the same day, with the same manure; thus both having an equal chance. Intending to sow a field that had been pared and burnt, with common Turnips, I procured my seed from the same source as the unsuccessful Swede seed, and prepared to sow very early. Fortunately for me the season was so dry that although the ground was ploughed it was impossible to work it for some weeks. In the meantime a farmer in the neighbourhood harvested some Turnip-seed, and I, thinking to make sure, procured some which I mixed with the rest, at the rate of 1½lbs. per acre of new seed to 2lbs. of old. I sowed five acres out of a six acre field with this mixture, and the plants are now up well and regular, but not at all too thick; in short, there is every prospect of a good crop. It is impossible to tell the age of the seed procured from the shop, though it is evident it did not vegetate to any extent; and had I depended entirely upon it, the crop would have failed. The remaining acre of the field was sown with 3½lbs. of the old seed, which came up so thick, I was obliged to harrow in some new seed. My reason for sowing all old seed on one acre was to have an acre of Tankards, the new being the White Globe. The single acre is in the middle of the field, and the Turnip-plants on each side are in a most flourishing condition.—*Arthur Hall, The Cwm, Chepstow.*

On Shell-fish as Manure.—An article in No. 29, extracted from the *Dumfries Courier*, on the successful results of experiments with shell-fish as manure, induces me to trouble you with a few remarks on the subject. Muscles and star-fish (five fingers, as the farmers call the latter) have long been an established manure in the neighbourhood of Faversham, in Kent. In a little work entitled "Practical Chemistry for Farmers and Landowners," published a few years ago, I adverted to this circumstance, and endeavoured to impress upon the attention of agriculturists residing near the coast, the advantages which they might derive from the use of these as manure, and the benefit they would at the same time confer on the community from the employment which the collection of them would afford to that hardy race of fishermen, which constitutes the nursery of our mercantile and national Navy. In the neighbourhood of Faversham, the muscles and star-fish are procured by dredging, and furnish bread to the free dredgers, who were nearly deprived of employment by the neglect or mismanagement of the oyster grounds belonging to the Corporation, on which they had depended for their subsistence. Muscles sell at 10*s.* the waggon load; "five fingers" at somewhat more—I think 21*s.* The farmers consider the latter the most efficacious manure; the reason of which the chemist would probably find in the greater proportion of phosphoric acid present in their hard covering. I have frequently counted between 12 and 20 waggon loads of one or the other leaving Faversham on a market day. There is scarcely a point of our coast which would not furnish, either by means of dredging, or by means of Leds left dry at low water, a valuable source of employment and a valuable mine of manure, which would restore a portion of those supplies of ammonia and the phosphates which our rivers are daily bearing from our sewers into the sea. In the same manner the freshwater muscle, the anodons and unios of our rivers, together with the large paludina, (a shell somewhat resembling in appearance the periwinkle or pin-patch) occasionally occur in sufficient quantities to be worth the attention of those experimenters who may be disposed to offer the unemployed population of the neighbourhood a fair price per bushel for collecting them. That small fish the stickleback has been, if it is not now, collected in large quantities for manure from the ditches of our fens, and I can see no reason why frogs should not be applied to the same purpose. They might be easily killed by sprinkling them with salt, which of itself is, in moderate quantities a valuable manure. We should thus, like the French, eat Frogs, though not exactly in the same form. But to return to the supplies of manure which marine animals are capable of furnishing:—The river Conway in Wales has long been celebrated for its pearls, which are even enumerated among the temptations which induced the Roman invasion of our island. Large pearls are occasionally found in the Unio margaritifera of the freshwater portion of the river, and small seed pearls are obtained in considerable quantities from the edible muscle (Mytilus edulis) of which there are large beds at the mouth of the estuary. The use to which these small pearls are applied, and the channel through which they are disposed of in London, have hitherto remained a secret, and the secret has conferred a monopoly of the traffic on parties who purchase them of the peasantry by the ounce, at such a price as renders the work of collecting them a source of remunerative labour, not only to women and children, but to men. The muscles, when collected, are boiled in large caldrons to cause the opening of the shells, and the mass being stirred and washed, the pearls are found at the bottom of the vessel. The refuse would form a valuable manure, but is, or at least was, a few years ago, left in large heaps on the shore. Perhaps this article, and that which you have extracted from the *Dumfries Courier*, may induce some of your readers residing near Conway, to make trial of it as manure. On stiff soils, the shells alone would be beneficial in some degree, though perhaps of little comparative value in a district where lime is so easily procured; but there can be no doubt that the mixture of the shells and boiled bodies of the animals would be highly efficacious. While we avail ourselves of the aid of commerce from the importation of foreign manures, let us not entirely lose sight of those supplies which lie unheeded at our own doors.—*J. Trimmer.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

In completion of our last week's Report of the Southampton Meeting we have to publish the following correction of Errata in our report of the award of premiums for Live Stock:—

Cattle of the Channel Island Breed.—The prize of 10 sovereigns, in Class 2d, for the best bull calved since the 1st of January, 1843, and more than one year old, was adjudged to Mr W. Woolcock, of St Peter's Parish, Hants, for his 1 year 8 months old Jersey bull, bred by Col. Le Couteur, of Belle Vue, Jersey.

Cattle of any Breed or Cross.—The prize of 15 sovereigns, in Class 4th for the best in calf heifer, not exceeding 3 years old, was adjudged to His Grace the Duke of Buckingham, for his 2 years 10 months old long horned heifer.

South Downs.—The second prize of 15 sovereigns, in class 2d, was adjudged to Mr Grantham, of Stoneham, near Lewes, for his 28 months old South Down ram, bred by himself.

Long woolled Sheep.—The second prize of 15 sovereigns, in Class 2d, was adjudged to Mr. I. Smith, of Charlbury, near Enstone, Oxon, for his 32 months old Oxfordshire ram, bred by himself.

Pigs.—The second prize of 5 sovereigns, for the second best boar of a small breed, in Class 2nd, was adjudged to Mr. T. M. Goodlake, of Wadley House, near Farringdon, for his 1 year 2 months old boar, of the Wadley breed, bred by himself.

We have also to make the following Addenda with reference to this section of our report:—

Extra Stock.

Bulls.—The Judges awarded 7*l.* to Mr. Michael Gosnall, of Eyeton Manor, near Shiffnall, for his 5 years 1 month old cow of the Leyton and Brutch cross breed. Also, 2*l.* to Mr. George Drake, of Manor Farm, East Tytherley, for his 10 months old pure Hereford bull calf. Also, 1*l.* to Mr. G. Drake, for his 6 months 3 days old cow-calf.

Long-woolled Sheep.—The Judges awarded 10*l.* to Mr. C. Large, of Broadwell, Burford, Oxon, for his 4 years 4 months old new Oxfordshire ewe.

Short woolled Sheep.—The Judges awarded 4*l.* to Mr. T. B. Northcott, of Tedworth, Marlborough, Wilts, for his 3 years 5 months old Southdown ram. Also, 2*l.* to Mr. T. B. Northcott, for his 3 years 5 months old Southdown ram. Also, 4*l* to Mr. W. Sainsbury, for his 3 years 7 months old Southdown ram.

Pigs.—The Judges awarded 3*l* to Mr. Hobbs, of Marksbell, for three months old improved Essex boar. Also, 2*l* to Mr Hobbs, for his 7 months old improved Essex boar. Also, 1*l* to Mr. W. J. Calhoun, of Binderton, Chichester, for his 10 months old Sussex sow. Also, 3*l* to Mr. Hobbs, for his 9 months old improved Essex sow.

Horses.—The Judges awarded 5*l* to Mr R. Curtis, of Basingstoke, for his 4 years 2 months old stallion. Also, 5*l.* to Mr John Thomas Glasspool, of Southampton, for his 3 years 3 months old three-parts bred mare

The following are the names of the gentlemen who officiated as judges of the stock:—

The judges of the *Short-horns* were Mr. Hugh Watson, of Keilor, near Angus; Mr W Torr, of Riby, near Caistor, Mr Charles Stokes, of Kingston, near Ragworth.

Of the Herefords—The Rev J Smythies, of Gray Friars, Colchester; Mr James Peake, of Hanwood, near Ross; Mr J. Ashdown, of Uppington, Shrewsbury.

Of the Devons—Mr J Hudson, of Castle Acre, near Swaffham, Mr J. Druce, of Eusham, near Oxford, Mr E Brankin, of Ascot, near Benson, Oxon

Of the Channel Islands Breed—Mr W. R. Browne, of Davenport-street, Bayswater; Mr J. Clayden, of Littlebury, Saffron Walden; Mr. M. Gibant, of Main Land, St. Lawrence, Jersey.

Of the Cross Breeds—Mr J Hall, of Wiseton Bawtry, Mr N. Smith, of Martley, Worcestershire, Mr H. Palfrey, of Upton-on-Severn.

Of the Leicesters—Mr. T Metcalf, Harleston, near Northampton; Mr. H. Bateman, Asthally, Witney, Oxon; Major Brown, Welbourne, Grantham.

Of the Southdowns—Mr T Weall of Woodcot Lodge, Croydon; Mr R Emery, of Harston Place, Storrington, the Hon W Gage, of Westhury, Bishop's Waltham.

Of the Long woolled—Mr W Gillett, of South Leigh, Witney, Mr J Elliott, of Chapel, Brampton, Mr. W Anderson, of Oakley, near Bedford

Of the Shorthorns—Mr J Chapman, 29 Park street, Dorset Square, Mr J Harris, of Hinton, Abingdon, Mr. T Morris, of Ranscombe, Lewes

Of Pigs—Mr John Farncomb, of 5, Patriot place, Brighton, Mr Jesse Kemp, of Utterby Grove, Louth, Mr. R J. Wiley, of Hornby, near Catterick.

Of the Horses—Mr W F Karkeek, of Truro, Cornwall, Mr Charles Bowman, of Greatford, Bourne, Mr. William Day, of Eusham, near Oxford

On Friday at noon, the general meeting of the Agricultural Society took place at the Victoria Archery-rooms. Earl Spencer took the chair. The thanks of the Society were presented to the Mayor and Corporation of Southampton, for the readiness which they had shown to meet the wishes of the Society, and to do all in their power to further its objects—also to Mr. Gater, upon whose land the light implements had been tried, for the exertion he had bestowed on the preparation of the light land; and to Mr. Spooner, of Ealing Farm, owner of the land on which the heavy implements were tried. The Marquess of Downshire then rose to propose that the thanks of the Society be given to Earl Spencer for the ability with which he had presided over the meetings of the Society during the whole of his presidency. He had no doubt that the great prosperity which the Society had attained was to be attributed mainly to the great interest evinced in its proceedings by the noble Earl, the zeal he had exhibited in carrying out its objects, and the great personal trouble and inconvenience to which he had put himself in order to give effect to its proceedings. Sir R. Price seconded the motion, which was carried by acclamation. Earl Spencer said that it had most undoubtedly been his earnest wish to promote to the utmost of his power the interests of the Society. He must be allowed the expression of his gratification that the Society in general, and this annual meeting in particular, had been so successful.—The thanks of the Society were then presented to the late Mayor of Southampton and to the Chairman and Board of Directors of the South Western Railway for the assistance they had given in bringing the cattle to the Show, and for the liberality they had evinced in reducing their charges to meet the occasion. The meeting then broke up.

Reviews.

Annual Register of Agricultural Implements, Southampton, 1844. By Cuthbert W. Johnson, Esq., F.R.S., &c., and James Hare. James Ridgway, Piccadilly.

The annual appearance of this work is very useful, as showing the progress made in English agricultural mechanics. Most of the different implements mentioned in it are illustrated by woodcuts, as well as by description. In the present case the work—a Guide to the Southampton Meeting—contains an interesting description, geological, agricultural, and historical, of the country between London and Southampton.

From this we extract the following, descriptive of the Wiltshire mode of managing water meadows:—

"In the autumn, the after Grass is eaten off quite bare, when the manager of the mead (provincially, the drowner) begins to clean out the main drain, and 'right up the works,' that is, to make good all the carriages and drains which the cattle have trodden in, so as to have one tier or pitch of work ready for drowning. This is immediately put under water, while the drowner is preparing the next pitch.

"In the flowing meadows this ought to be done, if possible, early enough in the autumn to have the whole meadow ready to catch the first floods after Michaelmas. The water then being the first washing of the arable lands on the sides of the chalk hills, as well as the first from the roads, is then thick and good; and this quality is to the superior riches of the flood-waters is commonly made in Berkshire and other parts of England. The length of the autumnal watering cannot be precisely stated, as much depends upon situation and circumstances; but if water can be commanded in abundance, the custom is to give meadows 'a thorough good soaking at first,' perhaps for a fortnight or three weeks, with an intermission of two or three days during that period, and continue for the space of two fortnights, allowing an interval of a week between them. The works are then made as dry as possible to encourage the growth of the Grass. This first soaking is to make the land sink and pitch close together—a circumstance of great consequence, not only to the quantity, but to the quality of the Grass, and particularly to encourage the shooting of new roots, which the Grass is continually forming to support the forced growth above.

"While the Grass grows freely, a fresh watering is not wanted; but as soon as it flags, the water must be repeated for a few days at a time, always keeping this fundamental rule in view—'to make the meadows as dry as possible after every watering, and to take off the water the moment any scum appears upon the land, which shows that it has already had water enough.'

"Some meadows that will require the water for three weeks in October, and the two following months, will not perhaps bear it a week in February or March, and sometimes scarcely two days in April and May.

"In the catch-meadows, which are watered by springs, the great object is to keep the works of them very dry between the intervals of watering; and as such situations are seldom affected by floods, and generally have too little water, it is necessary to make the most of the water by catching and rousing it as often as possible; and as the upper works of every pitch will be liable to get more water than those lower down, a longer time should be given to the latter, so as to make them as equal as possible."—(*Davis's Agriculture of Wiltshire*, p. 125—7.)

"In Berkshire they first flood their water-meadows about Michaelmas; these are situated principally on the banks of the Kennet. The first flooding they deem the richest in quality; this they keep on the land for about four days, then they dry it for about a fortnight, and then the water is let on for three or four days more. Those meadows which are the most readily dried are the most productive. There are none more so in fact than those which have a porous, gravelly, or broken flint bottom, from which the flood-water readily escapes, almost without drains. They begin to feed their meadows with sheep about the 6th of April, and continue feeding till about the 21st of May, when the meadows are again flooded for a crop of Hay; the land is then flooded and dried alternately for three days until Hay-time.

"The land in Wiltshire, under this kind of management, has been computed, and with a tolerable degree of accuracy, to be between 15,000 and 20,000 acres. Some considerable additions, however, have been made to the water-meadows of the district since this calculation was made. (*Davis's Wilts*, p. 122.) About the same number of acres are formed into water-meadows in Berkshire, and a still larger number in Hampshire."

Miscellaneous.

Sheep Salve.—Having left the south country, I came to Fife, and got employment on the farm of Bailo, on the Lomond Hills. At that place, power was given me to manage the sheep entirely after my own fashion, and after much thought on the subject, and seeing so much harm done by the usual salves, I set myself to consider what were the real objects to be gained by salving. I considered they were twofold; first, the destruction of vermin, and, second, the growth of wool of superior quality. Now, it is clear that the more innocent the substances used, so much the better will it be for the sheep as well as the wool; for, in looking at the composition of the usual salves, it is easy to see that the tar, the turpentine, the juice of tobacco, and arsenic, are all merely calculated to kill vermin, and cannot possibly be beneficial to wool, but rather detrimental; while the absorption of a portion of any of them through the pores of the skin cannot fail to hurt the animal more or less, according to the quantity absorbed. Butter, therefore, appeared to be the only article that could benefit the wool, and at the same time not hurt the sheep. I then considered that possibly oil of the cheapest sort, and used by itself, would serve the intended purposes; but as oil runs off too easily by the heat of the sun, or even by that of the sheep themselves, it occurred to me to mix it with a portion of tallow, which, while it is very nearly of the same nature, would tend to harden the salve, so as to retain it, and I wished to prove this by experiment. I felt assured that I would get superior wool, and I hoped and trusted that it would also prevent vermin on the sheep; but feeling some doubt on the propriety of leaving the tar entirely out, I mixed a portion amongst the oil and tallow in my first experiment. I mixed equal portions of tallow and train oil, weighing together 12 lbs., with 8 pints (16 quarts) of tar, for 100 hogs. I then smeared 400 with that sort of salve, and it proved much better in its results than anything I had ever seen before, both for quantity and quality of wool, and the vermin were also kept away. The wool-stapler said he had never had a clip come through his hands equal to it. Encouraged by this success, I next year left out the tar entirely, and smeared 400 hogs with tallow and oil alone, in the proportions given above; and I found that I had a still larger growth of wool, and of superior quality, so much so, that it realised in the market some

shillings per stone more than any wool cured by salves containing tar—at the same time the advantage to the sheep was most decidedly apparent. From these results I have no hesitation in saying that oil and tallow form the best salve for sheep of any that has hitherto been tried; and that, if the sheep-farmers of Scotland would use that salve alone, they would find their advantage in obtaining—1st, about a third more money for their wool, on account of its superior quality and purity; and, 2d, an improved condition of their sheep. But as long custom renders people unwilling to leave off old habits, it will be difficult to convince them of the propriety of the change, and particularly as to refraining from the use of tar, which was long the only substance used. For this reason I would recommend farmers to try the oil and tallow mixed with a portion of tar, to begin with, and afterwards to dispense with it by gradual decrease; or to try the oil and tallow on a few sheep only, and compare these carefully with other sheep under the usual treatment, and I have no fear of the result being entirely in favour of the oil and tallow, both in regard to satisfaction as well as profit.—*Mr. Stewart, in the Transactions of the Highland Society.*

Manufacture of Butter.—From the account of the experiments of Professor Trail, contained in the Transactions of the Highland Agricultural Society, are derived the following results:—"1. That the addition of some cold water facilitates the process, or the separation of butter, especially when the cream is thick and the weather hot.—2. That cream alone is more easily churned than a mixture of cream and milk.—3. That butter produced from sweet cream has the finest flavour when fresh, and appears to keep longest without acquiring rancidity; but the buttermilk so obtained is poor, and small in quantity.—4. That the scalding of the cream, according to the Devonshire method, yields the largest quantity of butter, which, if intended for immediate use, is agreeable to the palate and readily saleable; but if intended to be salted, is most liable to acquire, by keeping, a rancid flavour. The process of scalding is troublesome, and the milk after the removal of the cream is poor, and often would be unsaleable, from the taste it has acquired from the heating.—5. That churning the milk and cream together, after they have become slightly acid, seems to be the most economical process, on the whole, because it yields a large quantity of excellent butter, and the buttermilk of good quality.—6. That the keeping of butter in a sound state appears to depend on its being obtained as free from uncombined albumen or casein and water as it can be, by means of washing and working the butter when taken from the churn."—*Report of Commissioners of Patents, U. S.*

Rent-day.—To those agents who, by good fortune, acquire the management of estates, and who have no experience but what they borrow from their friends, the author begs them to get practical men to set out and superintend the work, and, in the face of the present times, assist the tenant in doing that which he cannot do himself, and, by so doing, enable him to procure his rent at the time it becomes due, instead of whipping him up and threatening him with distress the moment he got into arrears, and thus meet him with a face all smiles and thankfulness, instead of one as long as a fiddle, and grievances to recount sufficient to fill a sheet of foolscap paper. There is no class of men upon earth so grateful as the British farmer. I do not mean the gentleman farmer, but the man who gets his living for himself and family from his farm, and whose all is invested in it; and there is no man whose heart is so light and happy as the farmer, who, with his half-year's rent in his pocket, can meet his landlord, or the agent of his landlord, with a smiling face, pay his rent, enjoy his dinner and a pipe afterwards, and then return home with the pleasing reflection to his family that he met his landlord, and that he behaved kindly to him, and promised him various things which required doing upon his farm. It is this class of farmers, too, who want assisting, as, when the harvest is over, he has to begin to sell his spring Corn to pay his servants' wages, his Wheat, part to pay his Michaelmas rent, and before Lady-day his stock-yard is cleared. Great rises in the market he never can reap the benefit of, because he cannot keep a Wheat-stack to look at; it is only the gentleman farmer who can derive any benefit from the sudden advance of the market. The system, too, of giving back 10 or 15 per cent., and in some instances 20 per cent., is bad in principle as well as in practice—it gives the landlord a fictitious rental, and returns to the tenant a sum of money in bad times, which he cannot afford to lay out upon his land, but uses for other purposes.—*Hutchinson on the Practical Drainage of Land.*

The Cultivation of Rape.—The value of Rape for spring food has frequently engaged the attention of your correspondents and yourself. You have on several occasions recommended the mode of raising the Rape-plants in a seed-bed, to be transplanted when Flax or Corn is removed; and you seem to doubt the success of sowing the seed after these crops are taken from the ground. I have for several years sown Rape on my Flax ground, broadcast, with perfect success. I would recommend sowing it at three times: the first as early as possible, which this year may probably be about the 1st August; the second about the middle of August; and the third on the 1st September. Rape sown on the 1st August will, in an ordinary season, give a good cutting very early in April; and that sown 1st September will last till the Clover is ready for cutting. The ground occupied by the Rape may be sown with Spring Vetches in May and June, in order to succeed the second cutting of Clover. A portion of the Flax-ground may be sown late in September with Winter Vetches, and another portion in February with Spring Vetches. These will come into use a full crop between the first and second cuttings of Clover, and may be succeeded with transplanted Swedish Turnips, which may be supplied in the best manner by thinning the sown Swedes to 6 inches at first, and, when the plants are strong, removing the alternate ones for transplanting. The ground on which Flax has grown is the best adapted for the treatment described, the Flax crop being the first taken from the ground. Two full crops of green food are thus secured in the same season. Manure must be given to the Rape and transplanted Turnips; but if the house-feeding system be carried out to the full extent, there will be no scarcity of manure for every purpose; and it is good economy to get the manure into the land as soon as possible after being collected. Rape and Vetches are essential to a complete system of house-feeding; they fill up the intervals in spring, summer, and autumn, when Turnips and Clover cannot be commanded. Cabbages, to a moderate extent, are also most useful. By planting early and late Cabbages in early spring alternately, the early kinds are brought forward for use in July and August; and the late, then standing at wide distances, have room to complete their growth by October and November.—*J. A., in the Dublin Farmers' Gazette.*

Notices to Correspondents.

BARLEY.—*Youell & Co.*—Your specimens (it arrived in a mutilated state) is a long ear of six-rowed Barley. The grain appears fine and plump.

BOOKS.—*J. R. Pearson.*—Sinclair's "Hortus Gramineus Woburnensis."

CAMELINA SATIVA.—*E. B.*—Mr. Sproule's directions for the cultivation of Flax may be safely followed in most particulars, with reference to this plant. See former Numbers of the *Gazette*. Further information hereafter.

COLTSFOOT.—*T. R. Avery.*—Your note of July 23 is the only one we have received from you. The best way to rid the land of Coltsfoot is perseverance in pulling the flowers in spring, and the leaves with as much root as possible whenever they appear.

EARLY SPRING CROPS.—*J. Rosetta.*—You may have Cabbages early in April, by sowing the seed of an early sort in beds now, and transplanting at the right time. And if you sow Vetches in September, on good soil, you may expect to be able to cut them early in May.

FAILURE OF CROPS.—*Leicestershire Farmer.*—The only chance of a remedy for your case, so far as we know, lies in sowing late Turnips; and in sowing early Cabbage, to transplant in October for use in April.

FIXATION OF AMMONIA.—*S. Newington.*—Burnt gypsum contains about half its weight of sulphuric acid. The greater certainty of its operation would induce us to prefer the latter, though at greater expense. Unquestionably, it is advisable to convert the carbonate of ammonia into sulphate, or some other fixed form of ammoniacal salt. The difference in price between sulphate and carbonate of ammonia arises from the mode of their manufacture. The former is prepared from gas water, most of which used to be wasted as useless.

GAS-LIME.—*Jack Spratt.*—If you first expose it for a considerable time to the air, it may be beneficially mixed with manure.

GYPSUM.—*W. T. B.*—This manure may be adulterated with lime. Purchase only from a respectable dealer. The application of more than is necessary to fix ammonia is not injurious, and may be beneficial. Gypsum is sold in powder; if you obtain it in the solid form, it may be pulverised by burning.

MANURES.—*L. O.*—The manure from the tan-yard, which you describe, is probably superior per bulk to ordinary farm-yard manure. Old ashes in night soil dilute it, and so far injure it; but they are not injurious in themselves.

POTASH.—*Constant Reader.*—This alkali can be applied to land as nitrate. Apply 1 cwt. of saltpetre, which is nitrate of potash, per acre.

POTATOES.—*Patto.*—Your abundant haulm justifies your anticipation of a good crop. Do not roll the plant down—we never heard of such a thing. Try the effect of pulling the blossoms.

SMALL FARMS.—*An Inquirer.*—We cannot learn that any question has been received from you on this subject. We heartily wish that Cobbett's perspicuity could be transferred to all writers on rural affairs. But how is that to be done? There are few men who are very clear-headed, and no education will render persons perspicuous whose ideas are perplexed.

TANNARD SWEDE.—*A Reader.*—There is a variety of this form; apply to your seedsman.

TURNIP CUTTERS.—*W. C.*—An implement of this class was exhibited at Southampton by Mr. Philipps, of Bristol, having a cross-cutting apparatus, reducing the finger-shaped pieces in which the Turnip is delivered to a uniform length of about ¼ inch. All roots are the better of being washed, whatever the mode in which they are to be given as food. Your other questions next week.

WIREWORM.—*Fudge.*—Now that they are actually at work on your Swedes, we know of no help for you.

MISCELLANEOUS.—*Claudiocestriensis.*—We do not know Mr. Smith's address, but a letter to him at Deanston would probably be forwarded.

***As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, July 29.—Per stone of 8 lbs.

Best Scots, Hereford's, &c.	3s	8	to	4s	0
Best Short Horns	3	4	3	8
Second quality Beasts	2	10	3	4
Calves	3	8	4	8
Pigs	3	0	3	8
Best Downs & Half-breds	3s	8	to	4s	0
Best Long-wools	3	6	3	8
Ewes and second quality	3	2	3	6
Lambs	4	0	4	10

Beasts, 2633; Sheep and Lambs, 27,530; Calves, 188; Pigs, 312.

The supply of Beasts to-day is large, and the trade very heavy; on the whole, prices are lower. 4s for the best Scots, &c., is quite an extreme quotation, not being generally realised; many of the best Short-horns, also, are sold under 3s 8d, and middling qualities are very heavy on hand—several remain unsold. The number of Sheep is larger than we have known for a long period, and, considering the quantity, the prices, although lower, are better than could be expected, showing a disposition to improvement, should the supply at all decrease, which is highly probable. Lamb is a shade lower, still, there are many buyers for the best qualities, which suffer but a small reduction. Calves are rather shorter, and a little better trade.

FRIDAY, Aug. 2.

We have a fair supply of fresh Beasts, which, with those left from last Monday, cause a large market. Trade is heavy, though we cannot quote prices any lower—indeed, the trade having been pretty good in the dead market since Monday, has caused a good attendance of buyers. The supply, also, of Sheep and Lambs is pretty good, but there is a good demand, and everything makes fully 2d per 8 lbs more than on Monday. Veal is rather better trade, there being several less than last week. Pork has also improved, the weather having been during the week favourable for the sale of this article.

Beasts, 807; Sheep and Lambs, 11,330; Calves, 414; Pigs, 270.
41, West Smithfield.

WOOL.—BRITISH, FRIDAY, AUG. 2.

Our English Wool Market continues active. The demand for nearly all descriptions is good, and prices have slightly advanced.

	per lb.					per lb.			
Long-wooled Wethers	1s	0d	to	1s	1d	Southdown Sheepskins	1s	1d	to	1s	2d
Do. Mongrels	1	1		1	2½	Kent Fleeces	1	1		1	1½
Southdown Fleeces	1	0		1	1						

JAMES PEARCE, Wool Broker.

COVENT GARDEN, Aug. 2.—In consequence of the late favourable weather, the supplies are amply sufficient to meet the demand. Fine apples of good quality are brought, and among them are some good Providences, Queens, and Montserrats. Some fine-looking bunches of Black Hamburgh and Muscat Grapes are to be met with, which are offered at nearly the same prices as last week. Peaches and Nectarines are not so large as we have seen them; and Apricots, although abundant, are very small. Orleans, Green Gages, and other kinds of Plums, are becoming more abundant; but Strawberries, Currants, Gooseberries, and Dessert Cherries, are getting scarcer, particularly the former; Cherries for preserving are plentiful. Of Pears, some good specimens of Jargonelle may be met with. The supply of Apples is good, and they are of larger size than they were last week; they consist chiefly of Junneting and a few Hawthorndeans. Abundance of good foreign Melons are in the market; but good English-grown varieties are scarce. A few Figs have been offered during the week at from 4d. to 6d. each. There has been little alteration in the price of Vegetables since our last Report. The late showers have favoured the growth of Peas, which continue to be well supplied, although not so abundantly as a few weeks back. Cauliflowers are fine, but they are becoming scarcer. Potatoes and Carrots are clean and good; French Beans are sufficient for the demand, and Celery is good for this early period of the season. Salading and Herbs of every kind are abundant. Cut Flowers consist of Combretum purpureum, Ceanothus azureus, Bignonia venusta, Alstromeria pelegrina, Carnations, Picotees, Heaths, Pelargoniums, Verbenas, Fuchsias, Gardenias, Roses, and a few Camellias.

FRUITS.

Pine Apple, per lb., 4s to 6s		Plums, per half-sieve, 2s 6d to 3s	
Hothouse Grapes, per lb., 6s to 9s		Strawberries, per gallon, 1s 6d to 2s	
Melons, each, 3s to 5s		Gooseberries, per hf.-sieve, 1s 6d to 4s	
Peaches, per dozen, 3s to 10s		Walnuts, pickl., per bush., 4s 6d to 5s 6d	
Apples, Dess., per bush., 2s 6d to 4s 6d		Oranges, per dozen, 1s to 3s	
— Kitchen, 2s 6d to 4s		— per 100, 5s to 14s	
Pears, Dess., per half-sv., 2s 6d to 3s		— bitter, per 100, 3s to 14s	
Cherries, Wall, per lb., 1s 6d to 2s 6d		Lemons, per dozen, 1s to 2s	
— Standards, per doz., 1s to 2s		— per 100, 5s to 14s

HOPS, FRIDAY, Aug. 2.

THE accounts are daily getting worse, and the duty is to day at 140,000*l.* Several lots of Hops have been sold during the week at better prices.

FARNHAM & SMITH, Hop-Factors.

MARK-LANE, MONDAY, July 29.

THE show of English Wheat by land carriage samples this morning was considerable, having, in addition to a liberal arrival, some portion of last week's remaining over unsold; the Millers evincing a total indifference to purchase, but little progress could be made with sales generally, even at a decline of 4*s.* to 5*s.* per qr. Foreign was equally difficult to dispose of, although offered at a reduction of 2*s.* to 3*s.* per qr.—Barley is very unsaleable, and the turn cheaper.—With the exception of new White Peas, which sell currently at our quotations, other descriptions, and Beans, are rather lower.—There was a fair quantity of Oats offering, which met a slow sale at a decline of 6*d.* per qr.—The nominal price of Flour remains unaltered, but the trade are generally selling at rather less money.

FRIDAY, Aug. 2.

The weather here since Monday having been changeable, and the accounts from many parts of the country describing it as bad, no disposition has been evinced to press sales of Wheat, either on Wednesday or this morning. The attendance of buyers was tolerably good, but holders not being inclined to accept the terms offered, very little business was transacted. The quantity entered for consumption during the week has been 47,533 qrs.—Barley and Beans are a very dull sale.—The greater part of the White Peas sold on Monday were refused; the show of samples this morning being large, they could not be disposed of, except at a decline of 4*s.* per qr. Maple and Grey remain unaltered.—The Oat-trade is very heavy, and foreign as well as stale qualities must be written 6*d.* to 1*s.* lower.

EDWARDS AND LAY.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating extremely very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Conservatories or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

GUANO (GENUINE PERUVIAN & BOLIVIAN)
ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, July 26, 1844.

GUANO.—For Sale, in bags of 1 cwt. each; just landed, with a succession of cargoes to arrive.

There being considerable variety in the qualities of Guano imported from different places, and indeed from the same island, each parcel will be chemically analysed with the utmost precision, to show its relative productive power. A copy of such analysis will be given to buyers, and also instructions as to the most approved mode of using the Guano, furnished by the experience of eminent Agriculturists in England and Scotland.

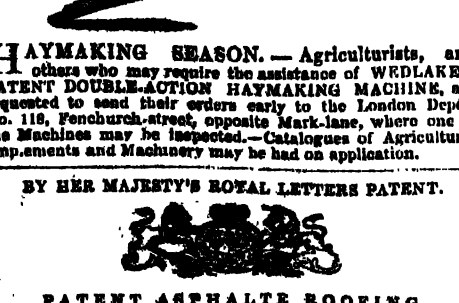
Large parcels will be delivered direct from the Ship, or waterside premises. Smaller quantities may be had at the warehouses, 24 and 25, Billiter-street; or delivered within any reasonable distance, at a trifling additional cost.—Apply to JAMES CLARK, 24, Billiter-street.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.



Price-current, London, June 12, 1844:—

WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street.

TO FLORISTS AND ADMIRERS OF FLOWERS.
BRAIN'S CONCENTRATED LIQUID GUANO, for the Garden, Shrubbery, Hothouse, and Conservatory.

This preparation is peculiarly adapted for the development of Flowers, furnishing them with the materials (in a soluble form) out of which they weave their delicate tissues and elaborate their beauteous colouring. It has no unpleasant smell, is easily applied, and thus recommends itself, either for the Garden or Drawing-room.—Price 1s. 9d. per quart Bottle, and may be had of most respectable Druggists and Seedsmen, with full directions for use inclosed.—Works, Thomas-st., Stamford-st., Blackfriars road.

HAYMAKING SEASON. — Agriculturists, and others who may require the assistance of WEDLAKE'S PATENT DOUBLE-ACTION HAYMAKING MACHINE, are requested to send their orders early to the London Depôt, No. 118, Fenchurch-street, opposite Mark-lane, where one of the Machines may be inspected.—Catalogues of Agricultural Implements and Machinery may be had on application.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 24 inches wide, at 1d. per foot, super. A discount to the trade.
THOS. J. CRAGGS, 9, Ingram-court, Fenchurch-st., London.

TURNIPS, &c.
DR. HALLETT'S DRY SOLUBLE FERTILISERS are composed of all the useful ingredients of the best Foreign Guano, which manure is already nearly exhausted, and no two parcels of which were ever alike. They contain also other ingredients equally useful, and are always to be produced of uniform strength; they are improvers of all soils, but most so of poor ones, and cannot possibly prove injurious to soil or crop, as they contain no heating or caustic materials, being simply and purely Fertilisers. Five cwt. of either of them is equal to nearly 20 tons of horse-manure as a Fertiliser. They are used, the one for all the varieties of Corn, Peas, Beans, Chicory, &c., and the other for Turnips, Mangold Wurzel, Natural and Artificial Grasses, and all Gardening purposes. This is the best protector yet discovered against the Fly in Turnips, for it gives a first growth three weeks beyond that of any other known Manure. Price of each Fertiliser, 10l. per ton, or 12s. per cwt.

Sold by MR. FOTHERGILL, 10, Upper Thames-street; and MR. G. HALLETT, at the [illegible] Wall, Blackfriars, London. The Fertilisers are manufactured under the immediate inspection of J. J. HALLETT, M.D., &c.

Agents for London, Messrs. WINSTANLEY, Chemists, 7, Poultry; Suffolk, Mr. W. REVANS, Yoxford; Norfolk, Messrs. BULLARD and WATTS, Norwich; Jersey, Mr. C. Kruger. Respectable country agents wanted.

KEENE'S PATENT MARBLE CEMENT.—This CEMENT is particularly adapted for the Walls and Floors of Conservatories and Greenhouses, being calculated, from its extreme hardness, to resist the wear incident to ordinary Plastering. For Floors it has a threefold advantage over Stone-paving. 1st, in its lightness; one inch in thickness of KEENE'S CEMENT suffering where 2 to 3-inch flagging would be employed. Next, in its appearance, combining, as it does, the hardness of stone with a uniform colour and even surface free from joints; and lastly, in economy, being one-third the price of Portland paving.

The most conclusive evidence can be given of the utility of KEENE'S CEMENT for these purposes by the Patentees and Manufacturers.—JOHN BAZLEY WHITE and SONS, Millbank-street, Westminster.

THE HARVEST.
DRUMMOND'S IMPROVED REAPING SCYTHE.—These Scythes, which continue to give great satisfaction for cutting Oats, Barley, and Wheat, are now offered for sale by the Subscribers, complete at 10s. each, or 12s. delivered in London, Liverpool, Hull, Belfast, or Londonderry. Should more than three be taken they will be sent free at 11s. each. *** Orders from other than regular customers to be accompanied with a remittance. W. DRUMMOND & SONS.

Agricultural Museum, Stirling, N.B., and 16, Dawson-street, Dublin.

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of searching thoroughly into the divisions of the teeth, and cleaning them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose—1s. An improved Clothes Brush, that cleans in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and successful manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the luxury of a genuine Smyrna Sponge. Only at METCALFE'S Sole Establishment, 130a, Oxford-street, one door from Hollis-street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6*, 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites; more wholesome and of less cost" —*Naval and Military Gazette*, April 8, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

BURBIDGE AND HEALY'S COOKING APPARATUS, combining Sylvester's Patents.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship; in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B. & H. can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made. A Prospectus can be forwarded, upon application, detailing particulars and prices, to 130, Fleet-street.

PRESERVES and CONFECTIONERY. — The superiority of BETTS'S PATENT BRANDY for PRESERVES and CONFECTIONERY, is testified by the fact that it is preferred to any other spirit by the most extensive WHOLESALE CONFECTIONERS in the METROPOLIS; for fortifying Home-made Wines it is invaluable; as an Ordinary Beverage it is congenial to the most delicate constitutions; and, as a Medical Stimulant, it is peculiarly adapted to persons of bilious or dyspeptic habits. Quantities of not less than Two Gallons, supplied at the Distillery, 7, Smithfield Bars, in Stone Jars, at 18s. per Gallon, exclusive of the price of the Jar; and in Glass Bottles, at 20s. per Gallon, Bottles and Case included.

CONSUMERS of BRANDY are respectfully informed, that J. T. BETTS, Jun., and Co., will not be responsible for any BOTTLED BRANDY that is not protected against fraudulent substitution, by the PATENT METALLIC CAPSULES, made of pure and solid metal (*not tin-foil*), embossed with the words "Betts's Patent Brandy, 7, Smithfield Bars," *to which attention is especially directed.*

EXTRACT FROM OLD MOORE'S ALMANAC for 1844.—"AUGUST.—CARE OF HEALTH.—This is generally the hottest month in the year; languor and inability for active mental and bodily exertion is experienced by all, but more especially by ladies and those of delicate constitution. Recourse should be had to that excellent medicine, Parr's Life Pills, which will quite re-invigorate the whole system, and render the heat of this month, which is otherwise so oppressive, as delightful as any month in the year."

PARR'S LIFE PILLS are sold by all respectable Medicine Vendors.

See the words "PARR'S LIFE PILLS," in White Letters on a Red Ground on the Government Stamp.

BRIGHT'S CUSTARD COMPOUND. — The ORIGINAL VEGETABLE PREPARATION, for making custards without eggs. Patronised by the Royal family, Nobility, and Gentry, with the approval and testimony, amongst many others, of the COOKS to SIX CROWNED HEADS. Sold in boxes at 1s. and 4s. each. Manufactory, 5, Holland-street, North Brixton, Surrey. Wholesale of all respectable houses, and retail by upwards of 1000 chemists, confectioners, grocers, Italian Warehousemen, &c., throughout the United Kingdom. Caution—Beware of imitations, and observe on all sent out the signature of the Inventor, JOHN BRIGHT.

AGRICULTURE, COMMERCE, NAVIGATION, THE CHURCH.—A. B. SAVORY and SONS, GOLDSMITHS, 14, Cornhill, London, opposite the Bank, have finished a few Splendid Pieces of PLATE, suitable for Presentation to Gentlemen connected with either of the above pursuits or professions, to which they invite the attention of committees who are in search of valuable testimonials for such occasions.

DOULTON AND WATTS, LAMBETH POTTERY and TERRA COTTA WORKS, High-street, Lambeth, London.

DOULTON and WATTS beg respectfully to solicit the attention of the Nobility and Gentry to the Figures, Vases, Fountains, &c., newly manufactured by them in Terra Cotta, the decided superiority of which over artificial Stone or Cement is well known. D. and W., from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, which being subjected to a high degree of fire, is rendered imperishable, and presents a sharpness and surface which no frost or changes of temperature can impair.

D. and W. are enabled to offer the above at a considerable reduction in price, and will forward Drawings and Designs Gratis on application.—Architectural work executed.

TO LADIES.
ROWLAND'S KALYDOR.—This Royally-Patronised and universally adopted Specific is a balmy, odoriferous, creamy Liquid, composed chiefly of extracts from the most rare Flowers and Herbs of an Eastern Clime. Its discovery was no less singular (by a Lady of rank), than its effects have been felicitous, during the last thirty years. It is the mildest and most efficacious preparation ever known for dissipating Tan, Pimples, Freckles, Discolorations, and other Disfigurements of the Skin. The radiant bloom it imparts to the Cheek, and the softness and delicacy it induces on the Hands, Arms, and Neck, render it indispensable to every Toilet.

Gentlemen will find it peculiarly grateful after shaving, in allaying irritation of the skin, and in rendering it soft and smooth.

Price 4s. 6d. and 8s. 6d. per Bottle, duty included.

CAUTION.—The great demand for this article excites the cupidity of *unprincipled Shopkeepers*, who vend the most *spurious trash* as the "GENUINE KALYDOR:"—when the genuine article is prepared solely by A. ROWLAND and Son, the amalgamation of its *costly exotic* materials renders any attempt to discover its component parts—thus proving the imposition of all other articles bearing the title of "KALYDOR." The genuine article has the words "ROWLAND'S KALYDOR" on the Wrapper.

*** All others are FRAUDULENT COUNTERFEITS!!!

IMPORTANT TO AGRICUTURISTS.

Now in the Press, the 2nd Edition,

A PRACTICAL ESSAY, with Proper Rules for the Application of GUANO AS A MANURE, arranged for all Soils and Crops, Horticulture and Greenhouse, with full instructions, reports, and results of the late Southampton Meeting, on the very extraordinary and beneficial effect produced from its application in Wheat, and so strongly recommended to be adopted at the approaching Wheat-seed season, as being a decided protection to the plant in severe weather, a preventive from the destruction of crops generally by the ravages of all insects, wireworm, &c., added to which the practical manner, reports, and results to be ascertained from the highly interesting meeting to take place on the 9th inst. at Glasgow, of the Highland and Agricultural Society of Scotland, who adopted Guano earlier, and more extensively introduced it than any Agriculturists or Societies in the United Kingdom.

Application [illegible] author only can be supplied, if by letter, post paid, [illegible] 6d.; and 1s 6d if to be posted prepaid and to inclose [illegible] Treatise on Guano, 2s.

N B —Genuine Guano supplied per ship at Liverpool, 6l 6s, and for spring delivery, 14l5, 6l. per ton. Payments by approved bills [illegible] three months date, or a discount allowed for cash — Direct to J. H. SHEPPARD, Chester.

WITH THE APPROVAL OF THE LORDS COMMISSIONERS OF HER MAJESTY'S TREASURY.

COMPLETION OF THE ZOOLOGY OF THE BEAGLE.

Published by J. CHURCHILL, Princes street, Soho; and may be had of all Booksellers and Newsvenders.

MIND COMPLAINTS, or NERVOUSNESS.—Clergymen, Noblemen, and all who suffer from groundless fear, suspicion, inquietude, &c., confusion, blushing, despondency, indecision, irresolution, head-ache, vertigo, loss of memory, delusion, inaptitude, for society, study, or business, blood to the head, restlessness, wretchedness, thoughts of self-injury, &c., can now not only be relieved, but tranquillised, made happy, and cured. The Rev. Dr. WILLIS MOSELEY, late of Cambridge University, after enduring these sufferings 14 years, discovered their cause, seat, and a perfect cure; and for 20 years has had no relapse. By the same means he has cured numerous clergymen, medical men, noblemen, &c.; and of 11,000 applicants, knows not 20 uncured who have followed his advice. Numerous testimonials can be seen, and references given. Most get well in six weeks Means of cure sent to all parts. Apply or write. At home from 11 to 3.—9, Charlotte-street, Bloomsbury.

FIFTY POUNDS REWARD.—The hard substance obtained by pressure from the Crude Cocoa-Nut Oil, is an essential ingredient in the PATENT COMPOSITE CANDLES; and, as EDWARD PRICE & Co, hold the Patents for this process, and grant no licences under them, it follows, either that the imitation Composite Candles are entirely different from the Patent one, or that the imitators are infringing the Patents the first is generally the case, but to protect themselves against the possibility of the other, EDWARD PRICE & Co. hereby engage to pay a reward of Fifty Pounds to any workman or other person, who may give such information respecting parties pressing Cocoa Nut Oil as shall lead to their conviction. The name of the informant will be kept strictly secret, and he need not take a prominent part in the proceedings, as all that E. P. & Co require, is the first clue to the discovery of the infringers, which they will then follow up for themselves This advertisement is being published in every newspaper of any circulation in the United Kingdom.

The Candles are now so well known to the Public, that it is hardly necessary to state here that they burn more brilliantly than the best wax, and give so large an amount of light, as to be cheaper, taking this into account, than the commonest Tallow Candles. They may be had of most of the respectable Tallow Chandlers throughout the kingdom, but purchasers must insist on being supplied with "PRICE'S PATENT CANDLES," otherwise they are liable to be deceived with some of the imitations, all called, like the real ones, "Composite." Those parties, really in the trade, who do not yet keep them for sale, are informed that they can purchase of the Patentees, or of Palmer & Co, Sutton-street, Clerkenwell, any quantity, large or small, at the Wholesale price, and that allowances are made in an increasing ratio, to parties taking to the amount of 50l, 100l., 150l, or 200l., at a time; and a very large allowance indeed to parties taking so large a quantity as to enable them to become wholesale agents for an entire district —Belmont Vauxhall. July 24th, 1844

Neatly bound in cloth, price 1s. 6d.,

THE SCIENTIFIC PHENOMENA OF DOMESTIC LIFE, as they are presented in the House or in a walk in the Fields, familiarly explained by CHARLES FOOTE GOWER, Esq., and arranged under the following heads:—The Bedroom; The Breakfast Parlour, The Morning Walk; The Kitchen; The Study; The Summer's Evening, &c. &c.

JAMES RIDGWAY, Piccadilly, and all Booksellers.

MR HOARE'S NEW WORK ON THE VINE:

This Day is published, 12mo. 5s. cloth,

A DESCRIPTIVE ACCOUNT OF A NEW METHOD of PLANTING and MANAGING the ROOTS of GRAPE VINES. By CLEMENT HOARE, Author of "A Treatise on the Cultivation of the Grape Vine on Open Walls."

London: LONGMAN, BROWN, GREEN, and LONGMANS.

Printed by WILLIAM BRADBURY, of Stoke Newington, and FREDERICK MULLETT EVANS, of No 7, Church-row, Stoke Newington, both in the county of Middlesex, printers, at their office in Lombard street, in the precinct of Whitefriars, in the City of London; and published by them at the office, No 5, Charles-street, in the parish of St. Paul's, Covent-Garden, in the said county, where all Advertisements and Communications are to be addressed to the Editor.—Saturday, August 3, 1844.

THE GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE.

A Stamped Newspaper of Rural Economy and General News.—The Horticultural Part Edited by Professor Lindley.

No. 32.—1844. SATURDAY, AUGUST 10. [Price 6d.

NURSERY OF L. VAN HOUTTE, at GHENT, BELGIUM.

GLADIOLUS GANDAVENSIS, V.H. (Glad. gandiensis, *Paxt.*)—Fine Bulbs at 10*s.* 6*d.* With the usual discount to the trade. N.B. All letters to Belgium must be paid.

CAMELLIA.—A Seedling Camellia, raised by a gentleman in the neighbourhood of Manchester, and named "Duke of Lancaster," a drawing of which may be seen at Mr. G. Charlwood's, 14, Tavistock-row, Covent Garden, London, from whom further information may be obtained; also at R. S. Yates's, St. Ann's square, Manchester.

PINE PLANTS.—Persons in want of the above have an opportunity of choosing from a particularly strong and healthy stock, warranted clean, at moderate prices. Apply personally or per post to W. Davis, Green-street, Marlboro'-road, Chelsea.

QUEEN VICTORIA FUCHSIA.

JOHN SMITH begs respectfully to inform his friends who have kindly favoured him with their orders for the above splendid FUCHSIA, that his stock only consists of a few Plants, and is therefore obliged to defer sending it out this year.
Dalston Nursery, August 8, 1844.

T. and J. BACKHOUSE, Nursery & Seedsmen, York, beg to offer to the public strong plants of the following new and rare species:—Achimenes picta, 18*s.* 6*d.*; Aristolochia gigas, 10*s.* 6*d.*; Lisianthus nigrescens, (small) 2*s.* 6*d.*

T. and J. B. have also a good stock of Lisianthus Russellianus, Phlox picta, Van Houttii and bicolor, 1*s.* 6*d.* each; Achimenes hirsuta, 2*s.* 6*d.*; and Pentstemon Murrayana, 2*s.* 6*d.*

J. and J. FAIRBAIRN, beg most respectfully to acquaint their friends and the public, that they have now many very interesting specimens of HEATHS in flower, which they feel assured will be found worthy of inspection. Open every day, (Sundays excepted) admission gratis.—Nurseries, Clapham, near London, Aug. 8, 1844.

INGA PULCHERRIMA. (Figured in "Paxton's Magazine of Botany" for August, 1844.)—Fine Plants of this extremely elegant and beautiful Exotic, with most of the other new and rare Plants of the season, may be obtained of the undersigned, at the following low prices:—

Inga pulcherrima, 7*s.* 6*d.*
Achimenes picta, 10*s.* 6*d.*
Æschynanthus Hornfieldii, 7*s.* 6*d.*
Amycia zygomeris, 7*s.* 6*d.*
Clerodendron splendens, 10*s.* 6*d.*
,, squamatum, 5*s.*
Hindsia, or Rondeletia longiflora, 18*s.*
Epacris campanulata rosea (the finest selected from 1000 seedlings), 7*s.* 6*d.*
Habrothamnus elegans, 15*s.*
Tremandra Hugelii, 10*s.* 6*d.* to 21*s.*
Veronica speciosa, 1*s.* to 15*s.*
Erica elegans, fine and healthy, 15*s.*, 24*s.*, and 30*s.* per doz.

Thomas Jackson, Kingston Nursery, Surrey, August 8.

THE WALCHEREN CAULIFLOWER.

MESSRS. MARNOCK and MANLEY beg to inform their friends and the public that they have a few packets of the above genuine article left, which should be sown for a general crop to stand the winter from the 12th to the 20th of August. Owing to the excessively dry season, the spring sowing has not turned out so favourable as it otherwise would have done; but they will warrant it to answer every description given of it in their treatise; Price, 4*s.* per ounce.
Nursery, Hackney, Aug. 8, 1844.

THE BEST TWENTY-FOUR VERBENAS EVER OFFERED, for 21*s.*, or TWELVE for 12*s.*

GEORGE SMITH begs to offer the following splendid Verbenas, which comprise the choicest varieties of the season. They were shown at the Royal Botanic Gardens of London, and were much admired for their fine form and distinct colours; they obtained the First Prize. Great Yarmouth Nursery, August 8, 1844.

KINGHORN'S NEW SPLENDID CALCEOLARIAS of 1844.

WILLIAM MAY, F.H.S., having been the fortunate purchaser of the entire stock of Five of the best sorts of Calceolarias raised by Mr. Kinghorn this season, and exhibited by him in May last (vide *Chronicle* and *Gazette* of May 25th,—the Editors of which pronounced them as very superior to "Lady Constable" and all others in present cultivation). The Five will be sent out in sets, of which due notice will be given. Parties wishing to possess these splendid varieties to address him at Hope Nursery, Bedale, Yorkshire.

W. M. has at present a fine stock of that beautiful new Exotic DRYMONIA PUNCTATA, which will be sent free on receipt of a Post-office order for 6*s.*; as also SEEDS of his very select varieties of PANSIES, CALCEOLARIAS, and HOLLYHOCK, in packets at 2*s.* 6*d.* and 5*s.* each, post free.

The Seeds may also be had of Mr. Watkinson, Horticultural Agent, &c., Market-place, Manchester, of whom may be ordered the Calceolarias, &c.

N.B.—W. M.'s newly published general Catalogue of Plants, with descriptions of his Calceolarias, Fuchsias, Geraniums, Pansies, Roses, Cinerarias, Camellias, &c. &c. may be had on application.

RARE, AND BEAUTIFUL; COLUMBINE.—The Subscribers beg to intimate that they have saved Seeds of a superb variety of Aquilegia glandulosa. This splendid Columbine is a hardy Perennial, and forms one of the most gay border-plants in cultivation; it grows to the height of from 12 to 18 inches, abounding in two coloured blossoms—blue and white—of the size and shape of the common Passion-flower. Packages of about 150 Seeds are sent free at One Shilling per packet, or for stamps of that value.
John Gibson and Co., Nurseries, Forres, N.B.

NEW SEEDLING PANSY.

JOSEPH FRYER begs to offer to the notice of the Public a very superior Seedling Pansy, named Standard, of which the following opinion has been given:—"Your Seedling Pansy is a decidedly good flower; the form as near perfection as anything we have seen; substance unobjectionable, good size (just covers a crown piece), and the colour rich and full; upper petals deep violet purple, with a band of the same colour round the lower ones, which are bright yellow; the eye of brownish crimson; full and distinct."—See "Florist's Journal" for July. Good Plants are now ready for sending out, postage free, at 3*s.* each, with trade allowance if 3 are taken.

J. F. likewise begs to remind his friends that he can now supply healthy young plants of most of the leading varieties of Pansies, from 8*s.* to 18*s.* per dozen, postage free. A remittance required from unknown correspondents.
Clarendon Nursery, Camberwell, London, Aug. 9.

MESSRS. J. AND H. BROWN are now sending out to any part of the Kingdom the following very desirable Plants:—

Chrysanthemums, newest and best varieties, by name, 9*s.* per dozen
Fuchsias, all the leading varieties, 6*s.* to 9*s.* per dozen
Angelonia grandiflora, 9*s.* per dozen
Scutellaria splendens, 9*s.* per dozen
Bouvardias, four varieties, 6*s.* per dozen
50 Hardy Herbaceous Plants, 25*s.*
100 ditto ditto 45*s.*
12 varieties of Tea-scented Roses, 9*s.* per dozen
Yellow Noisette and Yellow and White China do., 9*s.* p. doz.
Fine New Buff Rose, Eliza Sauvage, 18*s.* per dozen
New Crimson Odorata Rose, 12*s.* per dozen
Alba and Rosa odorata do., 9*s.* per dozen
Fine Blooming Plants of Achimenes grandiflora, longiflora, pedunculata, and rosea, 6*s.* per doz.; hirsuta, 1*s.* 6*d.* each
The new Achimenes picta, 7*s.* 6*d.* each
Gesnera tuhiflora, fine new white, 2*s.* 6*d.* each
Pentas carnea, 3*s.* 6*d.*; Thunbergia chrysops, 7*s.* 6*d.*; Inga pulcherrima, 5*s.*; Veronica speciosa, 3*s.* 6*d.*; Brugmansia floribunda, 2*s.* 6*d.* each
Fine Cineraria, Primula, Calceolaria, and choice Geranium Seed, 1*s.* per paper; and other Flower-seed, 3*d.* and 6*d.*, can be sent by post, for stamps.
Albion Nursery, Stoke Newington, London.

EXHIBITION OF LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment Florist to Her Majesty, begs to inform the Nobility, Gentry, and Amateurs, that his extensive assortment of this most beautiful Lily, which has been so much admired, is in flower, and will continue in perfection about three weeks, and may be viewed every day, Sundays excepted. Admittance Gratis.
Clapham Rise, August 10, 1844.

DUTCH FLOWER BULBS.

J. CARTER, Seedsman and Florist, 238, High Holborn, London, respectfully informs the Nobility, Gentry, and his Customers in general, that his Annual Catalogue of Genuine Dutch Bulbs, &c. will be published as usual on the 1st of September, and that it will immediately be forwarded to his Customers. In case of accidental omission, he begs to be reminded thereof.

The annexed Advertisement contains a List of such Seeds as are proper for sowing during this and half the following month, with this exception, that Double Hollyhock, Queen, and Brompton Stock should be sown immediately.

FLORICULTURAL SEEDS.

J. CARTER, Seedsman and Florist, No. 238, High Holborn, London, begs leave to recommend the following Seeds for present and autumn sowing. The Annuals he has selected will flower in the autumn if sown this month. He would recommend a second sowing early in September; for those sown in the autumn will flower earlier, and much finer than the spring sown, particularly in dry seasons like the present. 1.—Hardy Annuals in Assortments.

8 fine Calliopsis	2*s.* 6*d.*	8 fine Schizanthus	2*s.* 6*d.*
8 — Clarkia	1 6	20 — *German Stocks.	5 0
12 — dwarf Larkspur	2 6	8 — *Tenweek	2 0
8 — tall Larkspur	1 6		
7 — Nemophila	2 0	40 — hardy Annuals	3 0
8 — Godetia	1 6	20 — ditto	4 0
6 — Gilia	1 0	10 — ditto	3 0

* All Stocks require protection in winter, the others not.

2.—Hardy Biennials and Perennials.

8 fine Campanula	2*s.* 6*d.*	40 fine Perennials	10 6
8 — Dianthus	2 0	20 — ditto	5 0
8 — Pentstemon	2 0	10 — ditto	2 6
8 — new Scabious	2 0	Antirrhinum, 10 fine var. mixed	2 6
6 — Antirrhinum	1 6	Delphinium, 8 ditto	2 6
6 — Aquilegia	1 6	Hollyhock, 16 fine var. mixed	1 0
20 — Hollyhock	4 0	Scabiosa, splendid new mixed	2 6
12 — *Queen Stocks	2 6		
6 — ditto	2 0		
5 — *Brompton	2 0		

3.—Greenhouse Seeds.

10 fine Sorts	4*s.* 6*d.*	Chinese Primrose, mix.	1*s.* 6*d.* Per packet.
8 — Climbers	4 0	Finest mixed Cineraria	1 6
8 — Alstræmeria	4 0	— Calceolaria	1 6
4 — Thunbergia	2 0	— Gloxinia	1 6
3 — Portulaca	1 6	— Erica	2 6
Phlox Drummondii, scarlet	1 0	— Gladiolus	1 6
Ditto, 20 var. mixed	1 0	— Verbena	1 0
8 fine Tropæolum	2 0		

And most other Flower Seeds contained in his General Catalogue for 1844.

*** A comprehensive Catalogue of Dutch Bulbs will be published at the usual time.

EARLIEST STRAWBERRY in CULTIVATION.—Strong Plants of the PRINCESS ALICE MAUDE STRAWBERRY, which has proved itself to be the earliest grown in this country, are now ready to be sent out, at 20*s.* per 100. As an Early Strawberry it has taken the first prize at all the Horticultural Exhibitions in the early part of the season. Also Plants of the British Queen, Deptford Pine, Prince Albert, and all the leading kinds. To be had of Warner and Warner, Seedsmen, 28, Cornhill, London.

SHILLING'S QUEEN CABBAGE.—This month and part of August being the time to sow Cabbage Seed for the Autumn and Spring Planting, J. & S. Shilling having a little Seed left of the above very superior kind, which they highly recommend to those who have not already tried it, beg to offer it to the Public generally, in half oz. packets, postage free, at 2*s.* 6*d.* each, on the receipt of postage stamps or a Post-office order.—Northwarnborough Nurseries, Odiham, Hants.

*** Agent for London, Mr. Keanan, 4, Great Russell-street Covent Garden.

MESSRS. EPPS beg respectfully to offer the following new and valuable Plants:—

Achimenes pictæ, 1s. 6d.	Gloxinia Cartwelli, 7s. 6d.
A. hirsuta, strong plants, 2s. 6d.	,, bicolor, 7s 6d.
Beddies Lindleyana, 7s. 6d.	,, magnifiora, 7s. 6d
Thunbergia chrysops	,, insignis, 7s. 6d. (these are the finest varieties known)
Drymonia punctata, 10s. 6d. (for description see Paxton's Magazine for June)	Begonia speciosa, 1s. 6d.
Habrothamnus fasciculatus, 5s.	Rose, Cloth of Gold, 7s. 6d.
Bougmansia suaveolens, 4s.	Fuchsia, 'Kentish Bride,' blue corolla, pink tube and sepals, decidedly the finest variety sent out this year, strong plants, 3s. 6d.
,, Knightii, 5s.	
Pentas carnea, 5s.	
Clerodendron incisifolium, 7s. 6d.	

Orders to be accompanied with a remittance or a respectable reference.—Tower Nursery, Maidstone, Aug. 8, 1844.

THE HAMPSHIRE BROWN COS LETTUCE.—Persons desirous of possessing a very superior LETTUCE during the winter and spring will *not* be disappointed if they sow the above kind any time this month. Sold by J. and S. Sibling, in ½ oz. packets, at 2s. 6d. each.

SIBLING'S QUEEN CABBAGE, which is highly recommended for garden purposes, should be sown immediately, for the autumn and spring planting, ½ oz. packets at 2s. 6d. each, sent free on the receipt of postage stamps or a Post-office order.

London Agent, Mr. Kernan, 4, Great Russell-street, Covent Garden.

P.S.—To purchasers of the Lettuce Seed the Advertisers take the liberty of recommending a few seeds being kept to sow in the spring, to prove it for the summer.

Northwarnboro' Nurseries, Odiham, Hants.

TO NOBLEMEN AND GENTLEMEN'S GARDENERS.

EARLY POTATO SEED.—Mr. SMITH having been very successful in raising Early Potatoes from the Seed of the Potato Plum, is happy in being able to offer Potatoes for seed of so early and fine a quality as has not been equalled. The first is his six weeks Dwarf Seedling. This is a very fine early Potato; so early that with ordinary cultivation it will be ready for use in six weeks from the time of planting. It is particularly well adapted for forcing, being so dwarfish in the stem as not to exceed from four to six inches in height. The Potato is very shallow-eyed, and of first-rate quality, but not large, the largest being about the size of a bantam's egg.—Price 10s. the imperial pound.

Second, his prize-taking Seedling. This is a very early, large, and fine Potato, shallow-eyed. It has taken the first prize at the Berwickshire Horticultural Shows during the last two years for its size, beauty, and good quality.—Price 15s. the imperial stone.

Third, his second Early Seedling. This is a Potato of first-rate quality—comes in class after the Prize taker; is a rich bearer and shallow-eyed, making up the blank between the first Early and what is commonly termed American or second Early.—Price 15s. the imperial stone.

Those wishing to be supplied with seed of any of the above Seedling Potatoes will address their order to Mr. Smith, Gardener, Ayton, Berwickshire, with a Post-office order for the amount of their demand. They are requested to give their address distinctly, that the Potatoes may be forwarded without delay to the proper quarter. Early application will be necessary to obtain a supply, as the stock is limited.

All orders will be punctually attended to, and the Potatoes forwarded, packed in boxes, with moss or hay, to protect them from injury by carriage. Ayton, Aug. 9, 1844. M. Smith.

BENTALL'S IMPROVED PAPER FOR DRYING PLANTS.

W. AND T. BENTALL earnestly invite the attention of Botanists to the above Paper; its perfect adaptation to the purpose for which it is prepared having been fully proved. The following valuable testimonial has been lately received:—

"I highly approve of your new Paper for drying plants, and consider it far preferable to the Cambridge Chalk Paper, which I previously employed, but which will now be entirely discarded by me in the preparation of plants for the herbarium. I have also found it most valuable in drying Algæ, the most decisive test, in my opinion, to which such papers can be subjected; and can safely recommend it to all engaged in the study of these plants."—*Rev. W. S. Hore, M.A. F.L.S., &c., Stoke, Devonport.*

Sir W. J. Hooker, K.H., L.L.D., &c. Professor Lindley, C. C. Babington, Esq., M.A. F.L.S. &c., H. C. Watson, Esq., F.L.S. &c., have also kindly allowed the use of their names as strongly recommending it. To be had of the Manufacturers, Halstead, Essex; and of their Agents, Mr. E. Newman, 9, Devonshire-street, Bishopsgate, London; and Mr. R. S. Melntosh, 12, Catherine-street, Edinburgh.

Sizes, 16 by 10 inches (when folded), 14s. per ream, 20 by 12 inches, 20s. do.; 16 by 20 inches, 28s. do.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and despatch.—This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by men or women. It is easily set, so as to deliver the exact quantity of Seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Mangold Wurzel Seed, Wheat, Barley, Peas, and all kind of Garden Seeds. 1*l.* 10*s.* each. Commission allowed to Agents.

These Dibbles may be obtained of Messrs. Cottam and Harlem, 2, Wimsley-st., Oxford-st., London, through the agency of the principal Agricultural Implement Sellers, in the United Kingdom; or from the Inventor, by letter, to his address, inclosing a Post-office order for the amount.—Richard Smith, Upper Hall, near Droitwich, Worcestershire.

HOTHOUSES, CONSERVATORIES, &c., made and fixed Complete in all parts of the Kingdom. One, two, and three-light Cucumber and Melon Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom; warranted best material. Two-light Boxes and Lights complete, from 1*l.* 8*s.* Garden-Lights made and glazed from 1*s.* per foot, at Jas. Watts' Sash Manufactory, Claremont-place, Old Kent-road. *** Reference given.

CONSTRUCTION OF HOTHOUSES, &c.

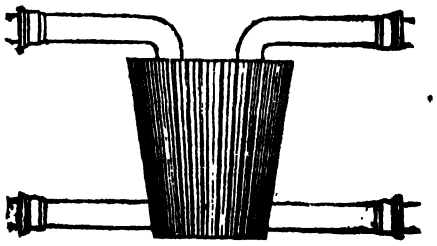
THE great want of skill in the construction of Old HOTHOUSES, &c., as well as in the cultivation of that most liberal of all plants, the VINE; the loss sustained on moneys expended on horticultural erections, without studying the convenience and capabilities of such erections being made available to the double purpose of a Stove and Vinery, must be manifest to all practical men. As every Hothouse, Stove, or Greenhouse, is convertible into a Vinery 7 months in every year, it is the intention of the writer, a thoroughly practical gardener, to offer his services, and tender his advice in alterations of old or new works of this kind, on such terms as must insure his engagement by all parties about to erect or alter buildings of this description. To all Amateurs, Gardeners, and others lacking skill, whose crop of Grapes or Vines have failed, within 7 miles of London, he offers his services, advice, and direction at attendance, from 1*l.* per year; and pledges himself to insure a crop on the principle of No cure, no pay, No crop, no money. For further particulars, apply by letter, inclosing 2 penny stamps, when a prospectus, &c. will be forwarded. Direct to Mr. Protheroe, Messrs. Gibbs, Seedsmen, Half-moon-street, Piccadilly, London.

LYNDON'S PATENT SPADE.—Sold by Green and Constable, Ironmongers, 86, King William-st., London-bridge. Horticultural Tool Chests, Bright Ladies' Spades, Morley's Patent Water Pots, Scott Vernon's Patent Hoes, with a general assortment of Garden Implements.

REFINED PLEASURE to LOVERS of BOTANY.—The Nobility and Gentry are respectfully informed that the splendid WARDIAN PLANT CASES, which excited so much attention and obtained a Medal at the Mile Chiswick Fête, are now on view at No. 39, Argyll-street, Regent-street.

The suggestions of Professor Lindley have been carefully carried out by the manufacturer, Mr. Ferrs, so as to elicit the entire approval of that eminent authority. The varied charms of Nature are aided by the gorgeous enrichments of Art; and the Invalid, however exalted her station, may now enjoy, at all seasons, the beauties of Flora, in a cabinet not unworthy a place in the most aristocratic mansions.—Apply to Mr. Nottingham, as above.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. Bailey also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. Bailey were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

BURRIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.

Burridge and Healy respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, Burridge and Healy refer them to the Horticultural Society's Gardens, Chiswick; also to Mr Glendinning, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.	Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
In. ft.	*s.*	*s. d.*	*s. d.*	*s. d.*		
10 1 5	20	7 6	6 6	2 6	30 feet.	12 to 20
Ribbed Boiler.						
10 2 2	20	10 6	7 6	2 6	50 to 70 ft. 4 in.	Under 25 to 40
12 2 15	30	12 6	7 6	3 6	80 to 125 feet.	40 to 65
14 3 10	35	17 5	8 6	4 6	150 to 250 feet.	65 to 100
18 5 5	42	25 0	9 6	5 6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24 8 15	50	35 0	8 6	7 6	500 to 600 feet.	

If 2-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. Mr. Rendle, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

CONICAL BOILERS.—The Boilers invented by John Rogers, Esq., are made of several sizes, and may be obtained of John Shewen, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road: Robinson's, Tooting; Pontey's, Plymouth; The Horticultural Society's Gardens, Chiswick, and in the Gardens of the Royal Botanical Society, Regents'-park.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL, and BRISTOL.
47, Lime-street, Aug. 8, 1844.

GUANO.—For Sale, in bags of 1 cwt. each; just landed, with a considerable quantity of cargoes to arrive.

There being considerable variety in the qualities of Guano imported from different places, and indeed from the same island, each parcel will be chemically analysed with the utmost precision, to show its relative productive power. A copy of such analysis will be given to buyers, and also instructions as to the most approved mode of using the Guano, furnished by the experience of eminent Agriculturists in England and Scotland.

Large parcels will be delivered direct from the Ship, or waterside premises. Smaller quantities may be had at the Warehouses, 24 and 25, Billiter-street; or delivered within any reasonable distance, at a trifling additional cost.—Apply to James Clark, 24, Billiter-street.

Sales by Auction.

TO NOBLEMEN, GENTLEMEN, SEEDSMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS have received instructions from T. and C. Lockhart, of the late Firm of T. and C. Lockhart and Duncan, in consequence of a dissolution of Partnership, to submit to public competition, by auction, on the premises at Parson's-green lane, Fulham, and at 136, Cheapside, London, about or before the 14th September next, the whole of the late partnership's Stock and Fixtures, of which further notice will be given.—This valuable Stock consists of a unique collection of BULBS and FLOWER-ROOTS of every description, which has been carefully selected, both at home and abroad, during the last 25 years, together with a quantity of the newest and most choice Flower Seeds, well worthy the attention of the trade; a newly-erected Hothouse with boiler and hot-water pipes, a capital brick-built pit, boxes, frames, handlights, six nests of seed-drawers, two desks, two bulb stages, hardy herbaceous and other plants, standard roses, a quantity of box edging, bushel and other measures, a Chubb's patent Iron safe, scales, weights, bags, paper, garden-utensils, cutlery, sieves, pots, sundries, &c. &c. &c.

May be viewed one week prior to the Sale, and Catalogues had.

BEDFORDSHIRE.—Very Eligible Freehold Estates in the parish of Sandy, cultivated as Garden Ground, and offering to Trustees safe and profitable Landed Investments, not to be influenced by any change in the Corn-laws. Also a Freehold Family Residence, and other property, at Caldecote. The whole Tithe-free and Land-Tax redeemed.

MESSRS. RUSHWORTH AND JARVIS are instructed by the Mortgagees, with the concurrence of the Devisees in Trust under the will, to sell by Auction, at Garraway's, London, on Friday, Aug. 23d, at 12 o'clock, in 15 Lots, (unless previously disposed of by private contract), a very desirable Freehold Property, comprising 170 acres of land, with two Farm Homesteads, situate at Beeston, in the parish of Sandy, a district proverbial for the remarkable richness and fertility of the soil, and highly valuable as garden ground; a portion of which was late in the occupation of the deceased, and the remainder is let on long leases to responsible tenants, at almost incredibly high rents; and substantial additional advantages to the property may be looked for from the newly projected Line of Railway, direct from London to York, which is contemplated will pass over this estate. There are likewise several Cottages, a Wheelwright's shop, and Beer-house, at Beeston Green. Also a spacious Family Residence, with possession, in a fine sporting country, and having extensive stabling and out-buildings; a Licensed Ale-house, eleven Cottages near thereto, and 4 acres of luxuriant garden ground adjoining, situate at Caldecote, only one and a-half mile distant from the preceding property, and equidistant with the capital Market Town of Bedford, and only 47 miles from London on the great north road.—Printed particulars, with plans, may be obtained on the premises at Caldecote, at the principal Inns in the neighbouring towns, and in London, of Messrs. Barker, Rose, and Norton, Solicitors, 50, Mark-lane; Messrs. Gregory, Faulkner, Gregory and Bourdillon, Solicitors, 1, Bedford-row; at Garraway's; and at the Offices of Messrs. Rushworth and Jarvis, Land Surveyors and Auctioneers, Saville-row, Regent-street, and 19, Change Alley, Cornhill.

RARE ORCHIDACEÆ FROM THE EAST INDIES.

MESSRS. J. C. AND S. STEVENS beg to announce they will sell by Auction at their Great Room, 38, King-street, Covent Garden, on Thursday, 15th Aug., at 1 o'clock, a case of Terrestrial and Aerial ORCHIDACEÆ, which have just arrived in fine Health, and gathered during the months of Jan. and Feb. last, on the Steeps of the Ghauts, in the Presidency of Bombay. On view 2 days prior to the sale, and Catalogues had of the Auctioneers, 38, King-street, Covent Garden.

TO FLORICULTURISTS, NURSERYMEN, & CONNOISEURS.

MR. E. E. STONE will sell by Auction, on the Premises, 22, Park Place West, Liverpool Road, Islington, on Tuesday, August 13th, at 12, a Splendid and Valuable Collection of FOREIGN PLANTS, comprising a superb assortment of Meluecacti, Euphorbia, Aloes, Verbenas, Fuchsias, and other Stove and Greenhouse Plants; an excellent Tulip Stage and Utensils; also the surplus Household Furniture, a Richtoned 6½ octave Piccolo. The whole the property of a gentleman removing. May be viewed the day prior, and morning of Sale; and Catalogues had on the Premises, and of Mr. Stone, 89, St. John Street, near Smithfield.

TO BE DISPOSED OF.—An Extensive and Old-Established COUNTRY NURSERY, where a considerable Business has been carried on for many years. Any respectable person with a knowledge of the business would find this concern worthy of immediate attention. Apply to Mr. George Gray, No. 23, New Corn Exchange, Mark-lane, London.

N.B.—None but principals will be treated with.

VALUABLE CHURCH-PREFERMENT.

TO BE SOLD, THE NEXT PRESENTATION to the RECTORY of RICKINGHALL INFERIOR, in SUFFOLK. The Incumbent is in the 66th year of his age, and the Net Income arising from the Commuted Tithes, Glebes, and Surplice Fees, average about 550*l.* per annum. Also, the NEXT PRESENTATION to the RECTORY of RICKINGHALL SUPERIOR, possessing a Net Income of 437*l.* per annum.

For further particulars apply to Mr. Burcham, Auctioneer, Norwich.

TO CAPITALISTS.

TO BE SOLD, to pay a clear Five per Cent., THE TOLLS arising from the Navigation of Vessels laden with Corn, Coals, Timber, Stone, &c. &c., passing along the River Waveney, from Beccles to Bungay, Suffolk, with a Capital Residence, Malting Office, Business Premises, &c., at Bungay.

The above Property is let on Lease at 1300*l.* per annum, six years of which Lease were unexpired at Lady-day last.

For Price and further Particulars apply to Mr. Burcham, Auctioneer, Norwich.

TO HORTICULTURAL BUILDERS.

A GENTLEMAN wishes for a PLAN and ESTIMATE for a small GREENHOUSE or CONSERVATORY, to be erected at the end of his Drawing-room (which end faces the west, and the front the south, and from which a door of communication opens), size 15 feet 6 inches by 12 feet; there is a return wall of 3 feet to be glazed with Drake's Sheet Glass, and finished in the best manner.—Direct to E. L., at the Office of this Paper.

The Gardeners' Chronicle.

SATURDAY, AUGUST 10, 1844.

THERE has lately been laid before the French Academy of Sciences a most important paper on FORESTING. The author, M. Chevandier, who appears to have the charge of one of the French forests, has been investigating the effect of water upon the produce of wood, and his results are not a little startling.

From a multitude of experiments made with trees growing on the sandstone of the Vosges, he has ascertained that, powerful an agent as water is well known to be, its effects are not in proportion to its quantity, but to the manner in which it communicates with the roots of trees. For example, he found that if the quantity of timber furnished by Spruce Firs in a given time, on a given space, in the swamps (*terrains fangeux*) of the Vosges is taken as 1, the produce in dry land will be about 2, in land so situated as to receive rain water as it falls between 4 and 5, and in stations where the soakage of running water maintains a continual freshness rather more than 6. He endeavoured, he says, to collect together all the cases where the same tree growing in the same soil and aspect, nevertheless had its roots in a different condition as to water. He felled them in large numbers, keeping an exact account of their age and of all the circumstances that appeared likely to have influenced their growth; and he found, upon comparing trees of the same age, growing in the same soil, that the differences produced by the action of water were constantly in the proportions above stated, so far as Spruce Firs are concerned, to which M. Chevandier's observations appear to have been confined.

The following figures, which have furnished the proportions alluded to, express the annual increase in dry wood of the Spruce Fir:—

	Kil.		Years.
Swampy land . . .	1.84	Mean age at which the Spruce is felled . .	101.88
Dry land	3.43	Ditto	71.57
Land watered with rain water . . .	6.25	Ditto	74.45
Land watered with running water . . .	11.57	Ditto	99.45

In order to show more strongly the value of these considerations, M. Chevandier gives the following average rate of growth of the Spruce Fir, when about 100 years old:—

In swampy land less than	1	kilogramme*
In dry land less than	3	,,
In land which is watered, about	20	,,

This gives for the total weight of a tree a century old—

100 kilogrammes	or ⅓ of a stere†
300 ,,	or 1 stere
2000 ,,	or 7 steres

according to the circumstances in which it has grown. "And if we calculate the value of a tree, reckoning its price to be according to its size, we arrive at this conclusion, that a seed of the Spruce Fir will become, at the end of a century, and according to the state of the soil with respect to water, a tree worth 1½ franc, or 7 francs, or 65 francs."

It is impossible to estimate too highly the value of facts like these, which deserve the most serious consideration of all planters. Nothing can show more clearly how much of the results of planting depend upon circumstances little taken into account. The value of irrigation in particular is very striking; and M. Chevandier strongly urges the owners of mountain woods to turn the favourable position of such places to account, by introducing a good system of ditching. The plan which he finds most advantageous is to cut on the hill-side horizontal ditches, about a yard wide and deep, and 12 to 15 yards apart, which will catch the rain as it runs down, and, afterwards soak into each other, so that what the uppermost ditch loses the next below it receives, and so on. Such a plan has been carried into effect in the forests belonging to the plate-glass works of Clichy, and he finds it neither expensive to make nor to keep in good order.

The facts elicited by M. Chevandier's experiments have a very wide range, and affect every branch of husbandry quite as much as growing Spruce Firs.

OUR readers are aware that very shortly after the appearance of this Journal we pointed out the many advantages possessed by NEW ZEALAND as a country for agricultural and horticultural emigrants. From time to time we have produced evidence of the correctness of our original views upon this subject, which we have never found it necessary to modify in the smallest degree. Nevertheless, the colony has, as our columns have also shown, fallen into a state of the greatest embarrassment, and the operations of the New Zealand Company have been brought to a stand-still. It was our intention some time since to advert to this unfortunate state of affairs; but we have deferred doing so until the Report of a Parliamentary Committee, appointed to inquire into the state of New Zealand, should be made public. That Report is before us.

It now appears that the distress of New Zealand has arisen—not from bad climate, sterile or uncultivable lands, open roadsteads, or the operations of land jobbers—but from monstrous mismanagement on the part of the Government Officers. The Committee declare "that the difficulties now experienced in New Zealand are mainly to be attributed to the fact, that in the measures which have been taken for establishing a British Colony in these Islands, those rules as to the mode in which colonisation ought to be conducted, which have been drawn from REASON and from experience, have not been sufficiently attended to;" and they have passed a series of resolutions, very strongly condemnatory of the conduct of the Colonial Office, or its agents. They declare that the local authorities have made a treaty with the natives, which is only *a part of a series of injudicious proceedings;* that their acknowledgments of a right of property on the part of the natives in all the wild land *was an error which has been productive of very injurious consequences;* and that the non-settlement of land claims (one of the first duties of the Government officers) *has been productive of great confusion and mischief.*

All political discussion being studiously excluded from our columns, we forbear from making any remark upon this announcement of the Committee; indeed, we only produce it in order to show that no kind of reason exists why confidence should be shaken in the excellence of the soil and climate of New Zealand for the purposes of British cultivators, and that the disasters of the settlers are owing to misgovernment, and nothing else. We expect with impatience the evidence as to the capabilities of New Zealand that has been elicited by the Parliamentary inquiry, and shall take the earliest possible opportunity of making it known. In the mean while, it is most satisfactory to learn, that in spite of difficulties thrown in the way of the settlers by those whose duty it was to assist them, the colony is steadily rising into importance. In the words of the Report of the Directors of the New Zealand Company, dated July 31—"It appears that the natural resources of the country are sufficient to outweigh impediments to prosperity occasioned by misgovernment. In the midst of the anxieties produced by the massacre at Wairoa, and the continued operation of the causes of that calamity, five vessels in the course of three months sailed from Wellington for London, entirely laden with the produce of the Company's settlements, consisting of oil, whalebone, flax, ornamental woods, and wool."

ON THE PURITY OF WATER.

EVERY one is aware that water varies very greatly in nature—some waters being what is termed soft, and therefore well adapted for washing, and various domestic purposes; whilst other waters are said to be hard, and are unsuitable for washing, &c. In fact, when we examine the numerous operations in the arts, in which water is employed, we find that the successful performance of most of them is more or less dependent on the purity of the water employed. For some purposes soft water is requisite, whilst for others hard water is preferable.

The purity of the water employed for gardening purposes is a matter of considerable importance, and therefore the causes which affect its purity, the substances which modify its properties, and the methods of purifying it, are all subjects of some interest to the gardener. The natural waters of the earth—namely, sea and spring water—are hard; they are not pure water, but contain a portion of saline and earthy matter dissolved in them. Sea-water contains by far the largest quantity of these substances; but spring-water also contains them; and, in consequence, both these sorts of water are hard. In order to purify such water, we have only to boil it, and convert it into vapour by heat. Pure water rises in the form of steam; the impurities of the water are not volatile—they cannot be raised in vapour by heat: hence they remain behind, whilst the water is converted into vapour, and obtained quite free from impurity when the vapour is cooled or condensed.

When we thus distil water, we do that on a small scale which is every day taking place on a large scale all over the surface of the globe. The heat of the sun every day raises a large quantity of water in vapour from the surface of the land as well as of the sea; and this vapour returns to the fluid state when cooled, descending to the surface of the earth in the forms of rain and dew. Rain-water is as much distilled water as that prepared artificially in a still; and therefore, as rain-water is free from earthy and saline impurities, it is the solvent of all natural waters.

A little consideration will convince us that though the water which comes from the clouds is pure and soft, or at most contains minute traces of such substances as it may find in its descent through the air, yet that when it reaches the surface of the earth and soaks into the soil, it must soon dissolve a small quantity of such salts of lime, &c., as the soil contains, and in consequence become hard again. The water of springs is always more or less hard, yet it has previously been soft, for springs are caused by an accumulation of rain-water, which has filtered or drained through the soil and strata below it, in passing through which it dissolves a small quantity of earthy matter, and in consequence becomes hard.

The substances which commonly exist in hard water are sulphate and carbonate of lime, either separately or together; and in greater or less quantity they give to most spring waters the character and property of hardness. Sulphate of lime, or gypsum, is soluble in water, but only to a small extent, 500 parts of water dissolving about one part of the sulphate, or in other words, every gallon of water being able to dissolve about 150 grains of sulphate of lime. Perfectly pure water does not dissolve carbonate of lime, but water which contains any carbonic acid gas readily dissolves a small quantity of carbonate of lime; now rain-water always contains a portion of this gas which it absorbs in passing through the atmosphere, and the presence of which does not give it any character of hardness, or at all interfere with its economical uses; hence rain-water is able to dissolve a small quantity of carbonate of lime, and therefore in passing through a soil containing either sulphate or carbonate of lime it dissolves a little of these substances, and becomes hard.

The water with which plants are naturally supplied, is the pure soft water which is condensed from the clouds; hard water containing much lime is not well suited for the nourishment of plants, and indeed the presence of any quantity of the salts of that earth in water, is found to kill many of the more delicate plants. It is obviously impossible to purify the water for gardens by artificial distillation, and besides it is generally unnecessary, for, as has just been stated, rain-water is distilled water, and it may readily be collected and preserved in tanks for use, for any reasonable time. Rain-water, which collects from a clean slate roof, contains nothing but a small quantity of carbonic acid, ammonia, and other matters derived from the atmosphere, which is greater of course in towns and the vicinity of places where much fuel is burnt, than in the free and open country. It also generally contains a small quantity of organic matter, derived from birds, insects, and other similar sources. These impurities, particularly if present in any quantity, cause a tendency in the water to become foul, but do not at all interfere with its uses for horticultural purposes. The water which drains from tile-roofs generally contains a portion of lime, derived from the mortar; but even then the quantity, except in particular cases, is but small. No good garden should be without rain-water tanks, well made, and properly covered, to prevent earth or rubbish falling in; and rain-water alone should be used for syringing, washing, or watering delicate plants. For common purposes, and where the supply of rain-water is insufficient, river or spring-water must be employed; but such water is always inferior for horticultural purposes to rain-water, being more or less contaminated with sulphate of lime.

Water which contains carbonate of lime, dissolved in consequence of the presence of carbonic acid, may be greatly improved by several means; if it be boiled, the carbonic acid gas is expelled; the carbonate of lime being then no longer soluble, falls as a white powder, and the water becomes soft. The same effect is gradually produced by mere exposure to air; it is found that spring-water of this kind, after some days' exposure, becomes milky, and throws down a quantity of carbonate of lime, as the carbonic acid is given off from the water. Lastly, such water may be purified by the addition of a little quick-lime, which takes the carbonic acid at once, forming carbonate of lime, which is insoluble, and therefore separates, together with that carbonate of lime which the water previously contained in solution, owing to the presence of carbonic acid.

Spring or river water, holding sulphate of lime in solution, may be purified by the addition of a little carbonated alkali; thus, when carbonate of potash or soda is added to such water, these salts decompose each other, sulphate of potash or soda is formed, together with carbonate of lime, and the latter, being insoluble, separates as a white powder. If only a small quantity of the alkaline carbonate is employed, it considerably improves the water, for the alkaline salts are less objectionable than the sulphate of lime. There is one practical difficulty in the use of this process, which is, that if the water contains any free carbonic acid, the presence of that substance prevents the precipitation of the carbonate of lime, by rendering it soluble in water; this can only be obviated in the manner before stated. Carbonate of ammonia would be far preferable than carbonate of potash or soda, inasmuch as the resulting salts of ammonia remaining in solution would be not merely harmless, but even beneficial; it is, however, unfortunately the case, that carbonate of ammonia does not precipitate lime so readily as the carbonates of the common fixed alkalies; the carbonate of lime formed remains in solution, in consequence of the presence of carbonic acid. Carbonate of ammonia contains,

* A kilogramme is about 2lbs. 8oz.

† A stere is rather more than 35 cubic feet.

in proportion, more carbonic acid than either carbonate of potash, soda, or lime; hence, when it decomposes salts of lime, there is more carbonic acid than the lime can combine with, and this excess, which remains in the water, renders the carbonate of lime formed also soluble. On the other hand, carbonate of potash or soda contain, in proportion, just as much carbonic acid as the carbonate of lime; consequently, when they are employed, there is no excess of carbonic acid set free, and the whole of the lime is precipitated. If, however, hard water of this kind is exposed to the air for some time after the addition of carbonate of ammonia, the whole, or at least by far the greater part of the lime is precipitated. Any liquid containing carbonate of ammonia (such as common liquid manure) may be used for this purpose; but it must always be remembered that the carbonate of lime will not precipitate until the excess of carbonic acid is expelled or has escaped.—*E. Solly.*

TREATMENT OF HALF-HARDY PLANTS DURING WINTER.

The two principal things to be guarded against in the preservation of half-hardy plants during the winter months, are frost and dampness—both very destructive in their influence, and both exerting that influence in a different manner. But although the natures of frost and dampness are of very opposite characters, and their modes of influence widely different, the presence of the one materially augments the influence of the other; and it follows, that by preventing one, we in a great measure guard against both.

The first thing, then, that should engage our attention, is dampness, for if this is present, frost is more severe. To prevent dempness there must be a free circulation of air; the plants must be placed on a dry bottom, and if they are in a situation which will admit of a fire occasionally, it will render the pits or house dry, but it should be used very sparingly, and only when absolutely necessary. When plants are housed for the winter, it is a common practice with many gardeners to plunge them (I speak only in reference to half-hardy kinds) in some moist substance, whereby they may, by the porosity of the pots, absorb sufficient moisture for their support, without having recourse to the watering-pot. There are no doubt many advantages in such a system, but the disadvantages far outweigh them. Damp is engendered; there is a continual evaporation going on; and if the weather should be such (as is often the case for weeks together) as to prevent the removal of the lights, in order to produce a free current of air, the moisture finds no means of escape, and thus accumulating, causes the young and imperfectly organised wood often to damp off. But even with all care and attention, damp will attack some plants, and generally those that are most succulent in their nature, or the young and tender tops of others. We should therefore watch narrowly, and remove every leaf or shoot affected, as damp not only destroys the individual immediately affected, but extends its influence to those in the neighbourhood of the one so affected. It is contagious. It engenders mould, which being a species of Fungus, is rapidly disseminated, attacking and destroying wherever the damp has prepared the leaves for its reception. Neither should plants be too much crowded, as that obstructs the free circulation of air.

Watering should of course be done sparingly, but still it will be required occasionally. Care, however, must be taken to preserve the foliage as dry as possible, as there being but little sun in winter, and that not of sufficient strength to evaporate the superabundant moisture rapidly, it quickly rots the leaves, especially of Pelargoniums, and similar plants having leaves which form a kind of dish in which the water accumulates in considerable quantities. When fire is had recourse to for drying the house or pits, choose a fine day, and give all the air possible, so that the moisture dislodged by the heat may be dispersed. It is an absurd custom (but still often practised) to attempt to dry a building by fire-heat when every aperture is closed. The damp is certainly removed from all the crevices, but the confined atmosphere becomes saturated with moisture, and coming in contact with the walls and other objects at a lower temperature than the atmosphere itself, this moisture becomes condensed, and runs down in streams, or stands upon the walls in large drops, not a particle of it escaping, there being no aperture for it to do so. Many plants are no doubt placed for convenience, and from other causes, in shady situations. Some kinds require such treatment. In all such cases, however, they should be removed, as autumn approaches, to some place where they may enjoy the full benefit of the sun and air, in order that their juices may become elaborated, and their young and tender shoots get well ripened.—*Walter Wakefield.*

Home Correspondence.

Fourcroya gigantea.—Two noble Agave-like plants in the stove of the Royal Botanic Gardens of Kew, which are considered to be the Fourcroya gigantea, Ventenat (*Agave fœtida*, L.), give promise of flowering in a very short time. They are nearly of the same size, caulescent; the stem is 2 feet 4 inches high, crowned with a noble tuft of sword-shaped leaves five to seven feet long, spreading in all directions, their thickened bases giving a height of 9 foot 2 inches additional (in all 3 feet 6 inches), from the summit of which, in the centre of the foliage, the flower-stalk springs. This flower-stalk was first perceptible on Wednesday of last week (July 24th); and attention was directed to it by a remarkable appearance of the plant, the thickened bases of the leaves separating, as it were, from each other, so as to leave a space between them, into which a penny-piece might be inserted, and the lower leaves falling down so as, in a measure, to conceal the stem. On the 28th July, Mr. J. Smith found that this flower-stalk had already gained a height of 6 feet 8 inches; and on the 30th, of 8 feet 6 inches. To-day (August the 1st), at noon, its height was 10 feet, and in girth, at the base, 1 foot 2¾ inches. Its present appearance is similar to that of a young shoot of Asparagus, but more tapering, coming, indeed to a very sharp point at the top. The scales are distant, and the lower ones are beginning to spread, while the rest are pressed close to the stalk; but none of them exhibit at present an appearance of flower-buds. The growth of the flower-stalk in the two plants has kept pace, the one with the other, in a very remarkable manner; there is scarcely a perceptible difference in height between them, and as each is in a tub about 3 feet high, the whole height of the plants from the floor may be estimated, at noon on the 1st of August, at 16 feet 6 inches. The inside of the stove where they are placed being 26 feet high, some of our friends have congratulated us on having ample space, without removing the lights; but, calculating from the few instances upon record of the flowering of this stately plant in England, we must reckon upon a length of 30 or 32 feet from the flower-stalk; and instructions are already given for an opening to be made over each plant in the roof. Those of your readers who may be disposed to see them, will find them in the house usually called the Conservatory, or that one which is distinctly seen from the green (of Kew) before entering the gardens. Fourcroya gigantea appears to have flowered for the first time in Europe in the Botanic Garden of Schönbrun, Vienna, and it was figured by Jacquin, in the "Icones Plantarum Rariorum," vol. ii. p. 379. Its flowering panicle was 32 feet high. Another specimen blossomed in the Paris garden in 1723, and was figured by De Candolle in the "Plantes Grasses," tab. 126. Ventenat has given the height of the flower-stalk at different dates. It was from the 9th of August to the 4th of September before it had attained to 10 feet. By the 25th of October it had reached its greatest elevation, 22 feet; its more rapid growth having been checked by exposure to cold. In 1821, a Fourcroya gigantea blossomed at the seat of the Right Hon. Earl Powis, of Walcot, in Shropshire, and a figure was given of it by Dr. Sims in the "Botanical Magazine," tab. 2250. It had attained a height in the flower-stalk of 30 feet. None of the figures now mentioned give anything like a good idea of the stateliness of the species of Fourcroya, partly owing to the necessity of giving it upon a very reduced scale, and partly owing to the vast size of the panicle, in proportion to the foliage, gigantic as the latter are. The crown of leaves is in all shown to be sessile, or nearly sessile; whereas our plants are, as all authors describe them, caulescent. According to the first edition of the "Hortus Kewensis," it was cultivated at Hampton Court garden in 1690. Being a species of slow growth, it is possible the Kew plants may be of that age, and derived from Hampton Court. The Fourcroya longæva, of Karwinski, a species allied to this, is said by the Mexicans to flower only once in 400 years; but our species is but a dwarf in comparison of that, of which beautiful representations are given by Zuccarini, in the 16th vol. of the "Nova Acta Acad. Nat. Curiosorum," and which is said to have a stem 40 to 50 feet high, and a flower-stalk 30 to 40 feet high. — *W. J. H., Kew, Royal Botanical Gardens.*

Scorching Effects of the Sun.—The spotting of Vine-leaves under glass, so fruitful a source of speculation at present with your correspondents, and on which some conflicting opinions are entertained, depends in many instances on sun and water, but not in the manner pointed out by the lenticular theorists. A drop of water, as you have shown, on the surface of a leaf, cannot concentrate the sun's rays, so as to burn the leaf on which it rests. The under-surface of the glass of a hothouse, however, on being bespattered with water from a syringe or engine, will leave drops of water adhering to it, of various sizes and degrees of convexity, forming plano-convex lenses, which will concentrate the sun's rays and act as burning-glasses on the leaves adjacent, scorching them with brown spots and destroying their beauty, independent of the loss of green surface for the vital functions of the plant. Although pointing this out as one of the causes of the spotting of the Vine and other plants near the glass of hothouses, I would by no means hold it forth as the only one; but the above may satisfy the anti-lens gentlemen that water may burn the leaf of a plant, although not exactly in the way hitherto held out by the opposite party. Scoresby, when in Greenland, set fire to gunpowder with a double-convex piece of ice; no wonder then that a leaf may be scorched with a plano-convex lens of water.—*Vitimus.* [With much deference to our correspondent, we must regard his explanation quite as unsatisfactory as the others. Water lenses will no doubt act as well as those of glass or ice: but how do the lenses get into focus? Are not the leaves too far off the glass? And do not the drops of water shift and change their form, and run down the glass before they can act? Besides other obvious difficulties.

Scorching Effects of the Sun.—I have a plot of Scotch Firs two to three feet high, about 5000 in number; on the night of the 25th July it was a drizzling rain, and the next morning, being the 26th, the sun got out very hot; early that morning, about 9 o'clock, I passed by them and found them quite brown, and now they look as if they had had a fire amongst them. This must either be the effect of the sun and dew, or there must have been a frost in the night; but either way the sun must be the cause of it. The plot faced the east; on the north-west side I had several plots of Scotch and Larch, and only a few scorched. I perceive for the last month in this neighbourhood we have had several frosts in the night.—*F. K. O., Cliff Vale.* [This is a specimen of the sort of reasoning applied to this subject. The scorching was caused by the sun, or the dew, or the frost—or something else. Very likely; but by which? Not by the sun, because the same thing happened on the north-west side.]

Charcoal, Preparation of Cuttings, &c.—The following are the results of a few experiments relative to the application of charcoal in the propagation of plants, and also on the preparation of cuttings for insertion. In the spring of 1842, I propagated a considerable number of various kinds of plants in different ways, and some of these in charcoal; I sifted some rather fine, into which I inserted cuttings made from the young wood of Abutilon striatum, and Lantana Sellowii, together with others made from Fuchsias, and various other kinds of greenhouse plants: these became well rooted in a comparatively short space of time. The Abutilons emitted roots in great abundance, and seemed particularly fond of charcoal-grains, small particles of which adhered to the rootlets in great quantity. These cuttings were inserted in charcoal alone; but notwithstanding the success attending the experiment, I prefer mixing the charcoal with a little good soil and silver-sand. Sand is, no doubt, the best ingredient for propagation, but where it is scarce (as it is in some places), charcoal will be found advantageous. I also used charcoal in propagating Pelargoniums, for which I prepared a mixture of charcoal and loamy soil of about equal parts; the charcoal was not sifted very fine; 48-sized pots were used, at the bottom of which I placed a little Moss, and filled up the remainder with the prepared compost. I inserted one cutting in the centre of each pot, and the whole of the pots were plunged to the rim in the bark-bed in a propagating-house, containing a gentle and steady heat. I never saw cuttings do so well as they have done, many as I have seen; in the space of ten days or a fortnight the roots were protruding through the bottom of the pots. The cuttings were then taken out of the bark-bed and hardened off, and in a short time they became fine healthy plants; although it was evident that the compost was suitable for them, it is not to that alone that I ascribe my success, but, in a great measure, to another cause, viz. that of properly preparing the cuttings. It is the common practice to cut through the joint and remove three or four of the lowermost leaves, but the removal of these (I am fully convinced) is of great disadvantage, as it is generally admitted that the foliage has an office to perform, viz. that of elaborating the sap or juices of the plant. The sap ascends up the minute vessels of the cuttings, and, entering the leaves already formed, and undergoing the elaborating process, is converted into cambium, or the proper juice of plants, by exposure to the influence of light and heat. Afterwards it descends, forming wood in its course, but in considerably less quantity in cuttings than in rooted plants. After it has reached the base of the cutting, it comes into immediate contact with the soil or compost, of whatever nature that may be, and there it assumes a congealed appearance, or white warty substance, which, owing to the sap continually descending, enlarges until it is forced into different directions in the shape of roots. These supply the plant with food, growth commences and proceeds, and the plant elongates and soon becomes established. If we deprive a cutting of its lowermost leaves, we deprive it of a considerable portion of its power to emit roots. I have inserted a great quantity with every leaf attached, and these retained the same healthy appearance as before they were taken off the parent plant; many of them rooted rapidly, and not one leaf died until after they had become well-established plants. It is evident that the leaves were of service to the cuttings, from their remaining so healthy; these cuttings were inserted deep enough to bury in the soil the whole of the leaf-stalk of the lowermost leaf. It is worthy of remark that those cuttings having the largest leaves, rooted quickest; thus showing that the descent of the sap was stronger and quicker in them than in others with smaller foliage, but which, nevertheless, also succeeded well. How different was the case of some tried on the old plan of removing the leaves! Many soon became languid, some ultimately withered away, and those which did succeed were much slower in emitting roots. In removing the leaves, generally a small portion of the foot-stalk is left, which sap enters, but on account of the leaf being absent, is not elaborated; consequently, these become dropsical, and damping off very often, kill the cutting. This would not have been the case, had the leaves been left on. In preparing cuttings, do not cut through the joint, but close at its base, as the vessels connected with the lowermost leaves are then retained entire, which is an advantage not to be lost sight of; the cut should be made with a sharp knife, in order that the cutting may not receive the slightest bruise. For fear of disorganising the vessels, the cut should likewise not be suffered to become dry before insertion, as this to a great extent deprives the cutting of the power of absorption, and perhaps, in some plants, altogether. Shading is another essential point. Plants breathe, as it were, rapidly under the solar influence; consequently cuttings, being without roots, are not possessed of sufficient power for absorbing a requisite quantity of moisture to counterbalance the evaporation, and the consequence is (if shading is not resorted to) the cutting very quickly flags or droops, and is soon past recovery. To allow them to flag at all, is giving a severe check to the whole system, and in order to obviate this, recourse must be had to

shading. With regard to the Pelargonium, I would state, that to retain the leaves on the cuttings is highly serviceable. This, however, does not answer all plants indiscriminately; for on many of the hard-wooded kinds the leaves have either none or but very short footstalks; in such cases, then, a few of the lowermost leaves must be taken away; for, if buried in the soil, they *rot*, and destroy the cuttings. But, with these exceptions, there is much advantage in retaining all the foliage entire. With respect to charcoal, I may state that, for Salvias, Petunias, Fuchsias, Verbenas, Heliotropiums, Anagallis, &c., together with several climbers, as Cobæa, Lophospermums, and the like, charcoal is an excellent ingredient in their propagation, when mixed with a portion of good soil. For drainage also its value is well known, as on account of its open, porous nature, it admits a free passage for water.—*H. A. Wood, Statfold Hall.*

Pine-apples.—The perfection of Pine-growing is to produce them throughout the whole year; and to accomplish this desirable object is the ambition of all gardeners who have them in constant demand. This regular and continued supply is not to be afforded by subjecting the entire stock to one uniform treatment and temperature, or to have the plants of one age and size. Supposing, for example, a house 100 feet long, and of the usual width, divided into three compartments—plants of the same size are placed in each, and each division heated to the same temperature, and a healthy growing atmosphere maintained; the result, under such circumstances, will be nearly the same, although each of the divisions may be differently arranged, as long as the temperature and treatment nearly assimilate. If "A. B. C." had attentively studied this important part of the alphabet of Pine-growing, he would not now be living in dread of all his Pine-plants coming into fruit at once, and in autumn. Had "A. B. C." selected those plants which were likely to come up first, and which the practised eye can easily detect, and placed them in one of the divisions of his house, and then maintained a higher and drier temperature, the result would have been other than disappointment. Mr. Macintosh knows, as well as any man, the value of a good Pine-apple at Christmas; hence the remark alluded to by "A. B. C." applies, in all probability, to such plants as are very small, or mere suckers, as no gardener, in these days, would think of casting to the rot-heap such plants as those described by "A. B. C." merely because they were about to afford him good Pine-apples during winter.—*R. Glendinning.*

Pine-apples.—In a late Number are some remarks on the Pine-apple, by Mr. Roberts, who writes thus:—"I do not agree with a statement in Macintosh's 'Practical Gardener,' which says, that Pines starting into fruit in August are tantamount to being lost;" but waving this statement, I proceed to another in the same communication, where Mr. Roberts says that Queens showing fruit in August, would ripen good fruit by the end of October—a space of little more than two months. Now, I beg to say, that neither Mr. R., nor any other person, ever did, or ever can produce a good fruit in so short a time, and in particular at that season of the year.—*M. S.*

Bees.—Amongst the great mass of useful information which weekly issues from your Journal, can you supply a poor persecuted amateur bee-keeper with directions how to make himself more agreeable to his bees? I have heard that these little vicious creatures entertain strong aversion to some persons, and I am almost constrained, from the sad experience I have had of their attacks on my own person, to coincide in the opinion. I have been stung five times this season; twice for just peeping at them through one of their side-windows, while they were at work, and on the other occasions I was at least a dozen yards from their dwelling. On last Friday, while working in my garden, some 14 or 15 yards in an opposite direction to their straight flight from the hives, I heard, about my head, a fierce buzz, which I was aware portended mischief, and before I could either run, or guard against the impending danger, I received my assailant's venomous weapon in the most prominent feature of my face; the little wretch tugged and tugged to recover its lance, but so deeply fixed was it, that to extract it proved beyond its power. I immediately hastened into the house, and having pulled out the sting, I applied liquor-potassæ, which I had seen recommended in a Number of the *Chronicle*, as a certain cure; but, alas! so rapid was the course of the virus that it seemed to have outstript the remedy which I was led to anticipate from the alkali; for after assiduously applying it till the part was completely blistered, my nose became twice its natural size, to the horror of my wife, and the scarcely suppressed mirth of my children; the swelling quickly spread over one side of my face. To market it was impossible to venture the next day, and even on Sunday I fear I was considered to carry a double face in church. Now, Sir, can any of your scientific or learned contributors suggest a remedy for my distressing case? What can put me on good terms with my bees? And if this be impracticable, is there no infallible means of counteracting the effects of their sting? Dr. Bevan mentioned volatile alkali as preferable to liquor-potassæ; if hartshorn be meant, I beg to state that in my case that has failed to afford relief. Pray pity my condition, and recommend an antidote to *A would-be Lover of Bees.*

Bedding out Plants.—When I plant out a bed of anything, if the season is likely to be dry, I first make a hole for the plant, and in the bottom of this I put some rotten dung, or any sort of material that will retain water; I water this well, and then put in the plant, filling the hole to within two inches of the surface; I again water well, and then fill up the hole, and in this way I proceed with all the rest. If I am obliged to water the plants afterwards, I cause the beds to be hoed over next day, as soon as they are dry enough; plants do better under this treatment than by watering them so much as is usually done; when there is no appearance of dew I damp the leaves over late in the evening. If I was to plant a bed and water it all over, it is very probable the roots that were deep in the soil would possibly not be touched, consequently they would naturally come to the surface in search of food, and next day when the water is all evaporated, they are left under the influence of a scorching sun. Now, if we can keep roots down until the bed becomes covered with foliage, the shade soon brings the roots to the surface; for instance, if we take a Pelargonium in a pot exposed to the sun, the roots are all at the bottom; but shade the soil with Moss or a similar material, they will come to the surface, and so it is with a bed of plants in the flower-garden.—*A. Threlkeld, gr. to J. Marshall, Esq.*

Bedded-out Plants.—I beg to differ from the statement of "W. P. A." respecting bedded-out plants in flower-gardens, for at the present time I could not possibly wish to see the beds here, one and all of them, in a more flourishing condition; the plants are looking well, both with regard to foliage and flower, and that without the use of the watering-pot, which has not been once employed since the time of planting out. The manner in which the beds are prepared is described at p. 619, 1842, and I imagine, if the soil is prepared as is there stated, that even in a season like this there will be no need of the watering-pot, shading, &c., which in nine cases out of ten does more harm than good.—*J. Clarke, Tandridge Court, Surrey.*

Gooseberries.—We have received from Mr. John Fardon, of Woodstock, the following statement of the weight of Gooseberries shown by him at Oxford, for which he obtained first prizes:—

Growth of Forest Trees.—The following passage occurs in Gilbert White's "Miscellaneous Observations" appended to most editions of his "Natural History of Selborne," and it in some measure illustrates this subject, on which you reply to "A Subscriber" in a late *Chronicle.*—*T. B., Selborne.*—"It has been the received opinion that trees grow in height only by their annual upper shoot. But my neighbour over the way, whose occupation confines him to one spot, assures me that trees are expanded and raised in the lower parts also. The reason that he gives is this: the point of one of my Firs began for the first time to peep over the opposite roof at the beginning of summer; but before the growing season was over, the whole shoot of the year, and three or four joints of the body beside, became visible to him as he sits on his form in his shop. According to this supposition, a tree may advance in height considerably, though the summer shoot should be destroyed every year."—*White's Selborne.*

Strawberries.—In all probability it is mice that have cut off "στρφον's" Elton Pine Strawberries, while green, close to the calyx. If he examines them he will find that they are divested of a great portion of their seed; I have suffered this season from the same depredators to a considerable amount. The remedy I employed was kitchen droppings mixed with arsenic: spread this on thin slices of bread, cut in small pieces; late in the evening lay it round the beds, and on the following morning pick up what is not used. With one application only I have got clear of the pests.—*R. Allan.*

Wasps.—These are very abundant this season, and great is the havoc they are making amongst the fruit. I have already destroyed upwards of 70 nests. My method of destroying them is very simple and effectual. I mix sulphur and gunpowder in about equal quantities, with a little water, to the consistence of a thick paste, and while this is soft, I cut it out into pieces of about a quarter or half an inch thick and an inch long, and when dry I roll each piece in a bit of match-paper. In applying it to the nest, I take a piece of stick and cleave it at one end; in this I fasten one end of the match paper, ignite the opposite end and hold it to the hole of the nest, and, allowing it to explode, I stop the hole with a clod or my foot, in order to prevent the smoke from escaping. In an instant the wasps are suffocated. I then dig out the combs and mix them up with the earth, for if they are not dug out and destroyed, they recover from their suffocation. — *R. Allan, Drumbanagher.* [Turpentine is a far better remedy, as Prof. Henslow stated last year.]

Societies.

HORTICULTURAL SOCIETY.

August 6th.—R. W. Barchard, Esq. in the Chair. The Marquess of Titchfield, Lord Saltoun, Sir F. Goodricke, Bart., Sir J. W. Guise, Bart., Sir H. Webster, Colonel R. Ferguson, G. G. Kirby, Esq., H. R. Yorke, Esq., M.P., T. Kelsall, Esq., W. Williams, Esq., T. Rawsthorne, Esq., and F. L. Popham, Esq. were elected Fellows; and Dr. T. Cantor, of Penang, a Foreign Corresponding Member. The Exhibition included several objects of great interest. Two magnificent specimens of Fuchsia exoniensis were contributed by Mr. Ayres, gr. to J. Cook, Esq. This Fuchsia is well known to produce flowers of the finest colour and best form; but when it was shown at a former Exhibition, some doubts were entertained with respect to its habit of growth. Mr. Ayres's specimens, however, furnished ample proof that this kind has not only the finest blossoms of any sort we yet possess, but has also an excellent habit. These plants were upwards of 5 feet high, and their gracefully drooping branches covering the pot, were loaded with blossoms, and were clothed from top to bottom with abundance of fine healthy foliage.—From the same gardens were Pentas carnea and Achimenes multiflora in very fine condition, and also another sort named Bentonii, bearing much resemblance to the old A. coccinea; together with a most beautiful Clerodendron paniculatum, in a state of great perfection, producing a spike of flowers fully 18 inches long. A Knightian Medal was given for this, and a Banksian was awarded to the three first-mentioned plants.—Mr. Mountjoy, of Ealing, was awarded a Knightian Medal for a most beautiful specimen of the red-flowering Lilium speciosum, having 4 branches, bearing no less than 70 of its showy blossoms. From the same collection was also Pentas carnea, a Gladiolus named Glory of Ghent, with large vermilion and yellow flowers, and apparently raised between G. cardinalis crossed with psittacinus, and specimens of Phlox Van Houttii, which, on account of its beautifully-striped flowers, is so great an acquisition to hardy herbaceous plants. Mr. Mountjoy also sent Gloxinia cerina, flowers of a seedling Lœasa, and a Plectranthus with pale-blue flowers.—Mr. Edmonds, gr. to the Duke of Devonshire, received a Knightian Medal for an excellent Cattleya crispa, in good health, and having 5 fine spikes loaded with showy blossoms.—From Messrs. Henderson, of Pine-apple Place, were Cleome pentaphylla, Linaria triornithophora, called flava, and a fine mass of Achimenes hirsuta, in profuse bloom, growing in a shallow pan. Messrs. Henderson stated that they grow all the varieties of Achimenes in shallow pans, and they imagine that the plants flower much better under such treatment than when they are planted in deep pots. It is probable that this, as well as some of the other sorts which are apt to become too luxuriant, and consequently flower but sparingly, would do better if they were grown on blocks, and were treated similarly to Orchidaceous epiphytes. This has been partly proved in the Garden of the Horticultural Society, where a bulb of A. pedunculata accidentally got into the Moss on a block along with one of the Orchidaceous plants, where it is now growing, and although one of the worst of them to flower, it is quite a mass of bloom. Messrs. Henderson also sent a new Heath, named Hendersonii, with bright pink flowers; and a fine specimen of Babingtonia camphorosmæ, a fine autumn-flowering plant, with Heath-like foliage, and producing fine spikes of delicate pink blossoms; a Banksian Medal was awarded for the Heath, Babingtonia camphorosmæ, and Achimenes hirsuta.—From Mr. Jackson, of Kingston, was a Lobelia-looking plant, with dark purple flowers, belonging to the genus Tupa, but named a species of Cristaria. It was from South America, and is new to gardens.—Mr. Robertson, gr. to Mrs. Lawrence, sent a plant of the very useful Niphæa oblonga, Oncidium Papilio superbum, volubile, and Stanhopea graveolens, called a variety of oculata; the pale variety of Cattleya Mossiæ, with large showy lilac blossoms; the insignificant-looking but rare Epidendrum glaucum, and another Orchidaceous plant, having small green flowers, with the lip striped with brown; several fine specimens of Heaths, and a magnificent Cuphea Melvilla, covered with blossoms, for which a Knightian Medal was awarded.—From the garden of G. F. Cox, Esq., of Stockwell, were some good Orchidaceous plants, including Cymbidium lancifolium, Cycnoches ventricosum, Catasetum Russellianum, with watery-looking pale-green flowers; the rare Sophronitis cernua, Eulophia cochlearis, small, but in good health; Oncidium Papilio, and the red and white varieties of Lilium speciosum, together with the beautiful Dendrobium chrysanthum, and the true Stanhopea oculata, for which, as well as for the Dendrobium, a Banksian Medal was awarded. — Good specimens of Fuchsia exoniensis were contributed by Mr. Kendall, of Stoke Newington, and Mr. Chandler of Vauxhall, confirming the fact so abundantly proved by Mr. Ayres's plants, that this Fuchsia has an excellent habit. Mr. Kendall also sent a seedling Pelargonium, named Warrior.—From Messrs. Lane and Son was a seedling Fuchsia, named Beauty Supreme; and another, called Pickwick, was from Mr. Cormack, of Deptford.—A specimen of the pale variety of Catasetum maculatum was sent from the garden of J. H. Schroder, Esq., of Brixton.—Messrs. Veitch and Son, of Exeter, exhibited what they considered to be a new species of Cyrtopodium, sent from Peru by their collector, Mr. Lobb, but which appeared to be only a pale variety of C. punctatum; and likewise Torenia asiatica, not of sufficient beauty to render it of much moment in a horticultural point of view.—Of Fruit there were some good specimens. Mr. Henderson, gr. to Sir G. Beaumont, Bart., was awarded a Knightian Medal for two fine Queen Pine Apples, weighing 4 lbs. 5 oz. and 4 lbs. 6 oz. They had small crowns, were perfectly ripened all over, and although not so large as some that have been formerly exhibited, they were excellent specimens of good Pine-growing. Mr. Henderson also showed another, called a Globe Pine, weighing 4 lbs. 5 oz.—From Mr. Fish, gr. to H. H. Oddie, Esq., was a Providence Pine, said to have been produced by a plant only 15 months old; it was not a remarkable specimen of growth—the weight, which was 7lbs. 2oz., was its principal merit. Mr. Fish also sent specimens of his hardy green-fleshed Melon, the heaviest of which weighed 6 lbs.—Mr. Povey, gr. to the Rev. J. Thornycroft, received a Knightian Medal for a Providence Pine, weighing 8 lbs. 13 oz., and measuring 22 in. round, and 7½ high—the number of pips in height was 10.

R was a remarkably handsome fruit; the crown was however, rather large.—Mr. Hamp, gr. to J. Thorne Esq., showed a Queen Pine, weighing 3 lbs. 14 oz., and a Black Jamaica of the same weight, they were stated to have been grown on the tank system.—Finally, Mr Bolton, gr. to C. Winn, Esq., was awarded a Banksian Medal for a handsome Brown Providence Pine, weighing 6 lbs. 11 oz., and measuring 18 in. round and 9 in high Mr. Bolton stated that the plant from which this was cut is only 12 months old, the sucker was taken off the old stool without roots in 1843, it was potted, and in February last was turned out of the pot into the bark-bed and planted in chopped turf mixed with a small quantity of charcoal The plant had been only five times watered with liquid manure since February. Mr Bolton writes, that beside this three other plants of the same age produced fruit each exceeding 6 lbs in weight —Mr. Barker gr to the Rev I Thurlow sent a large mass of the fruit of Musa Cavendishii which was over ripe in the centre, while the point was quite green, thus showing the fruit which ripens in succession, in the different stages of growth —Specimens of a Seedling Cherry were sent by Mr. R Buck, of Blackheath — E. Thompson Esq, of Stanely Hall, received a Knightian Medal for 3 fine bunches of Black Hamburgh Grapes the heaviest of which weighed 1 lb 8 oz., and also for three beautiful bunches of Black Prince, (called Lombardy) weighing 1 lb 8 oz. and 1 lb 6 oz —From the garden of the Society was the well known Mormodes aromaticum Catasetum Russellianum, and a new variety of Dendrobium secundum, received from Mr. Fortune, who found it growing about Anger Point. It produces beautiful racemes of dark purple blossoms, which are quite different from the pale flowers of the old species From the same collection was also the new Achimenes picta which independently of the beauty of its flowers has a pretty greyish-striped foliage that the others do not possess. Along with this was A longiflora and grandiflora the smaller variety of Erica cubica, the well known Stephanotus floribundus, Statice Dickensoni, Myoporum parvifolium, Clerodendron fœtidum, and a collection of cut flowers of Verbenas.

COUNTRY SHOWS.

Royal Berkshire Horticultural Society July 25 —This was the second Show for the season The following is a list of Prizes

Carnations 1st Mr Willmer for Lawton's Marquess of Westminster, Willmer's Bompland, Middlesex Hero Tilbrook's Grenadier Smith's Mrs Betts, Wilson's Harriet Strong's Duke of York Defiance, Brown's do Watts's Bishop of Gloucester, Jacques's Phœbus Hedley's William Cobbett Duke of Northumberland, Hepworth's Brilliant Babbins's Squire Mayhew Queen's Duchess of Kent Holmes's Count Paulini, Willmer's Prince of Wales, and others 12 varieties Messrs Lyne and Son for Stone's Venus, Brocken's Flora's Garland Brinkley's Defiance, Ely's Mr Fuller Conquering Hero Fewcher's Dr John, Pearson's Enchantress, Headley's Achilles Smith's Duke of Wellington, Hero of Middlesex Turner's Princess Charlotte and Wilson's Harriet *Amateur's List* 12 varieties Rev A H Matthews, for Strong's Duke of York, Brickett's Defiance Cant's Victoria, Hales's Prince Albert, Strong's Esther Duke of Northumberland, Ely's Lord Milton, Ely's Lady Ely Scorah's Bloomsbury, Brown's Bishop of Gloucester Mansley and Beauty of Woodhouse *Feathers* 1 Mr Willmer for Wells's Duke, Masson's Charlotte Jessop's Sir W Middleton Fly's Criterion, Glidden's Miss Hemsell Leaver Lydia Barnard's Miss Barnard Glidden's Sir R Peel, Brutton's Queen Victoria Kirtland's Princess Augusta Sykes's Flora Willmer's Princess Royal, Queen Adelaide Wilson's Isabella Barrard's Bloomer, Ely's John Bull Green's Victoria, Cook's Veronica and Glidden's Vespasian 12 varieties 1 Rev A. H Matthews for Willmer's Princess Royal West's Matilda Burrough's Mrs Bowyer, Matthews's Enchantress Tillworth's Isabella Sir William Middleton, Matthews's Cynthia Green's Victoria Cook's Victoria, Brinkley's Perfection Matthews's Regina and Trip to Cambridge 2 Mr West for Glidden's Princess Royal Trip to Cambridge, Glidden's Vespasian Matilda Sharp's Miss Vicars, Kirtland's Queen Turner's Queen Nos 24 31 Mr Cook for Princess Royal Wilson's Flagstaff Trip to Cambridge, Wain's Victoria Cook's John Hampden, Kent and Queen, Cook's Venus West's Matilda and No 1

Guildford Horticultural Society July 25 —This was the first meeting for the season Several prizes were awarded but we have only received a list of rewards without the names of the flowers for which they were given

Northampton Horticultural Society July 10 —At this the Annual Meeting the following prizes were awarded —*Scarlet Bizarres* 1, Mr Holliday for Harvey's Conqueror 2, Mr Jenkins, for Martin's Spitfire 3 Mr Jacquest for the same *Crimson Bizarres* 1 Mr Holliday for Ely's Earl Milton 2 Mr. Cheny, for Wakefield's Paul Pry 3 Mr Carter, for the same *Scarlet Flakes* 1, Mr Carter for a seedling 2 Mr Holliday, for Addenbrooke's Lilia 3 Mr Archer for Wilson's William the Fourth 4, Mr Cheny for Chadwick's Brilliant 5, Mr Hardwick, for a Seedling *Rose Flakes* Mr Holliday for a seedling, called Duchess of Buccleuch 2 Mr Bullock for Mr George Crowe 3, Mr Hardwick for Lady Ely 4 Mr Bullock, for Mr George Crowe *Purple Flakes* 1 Mr Weston, for Harvey's Commander; 2, Mr Holliday for Evans's Queen Victoria; 3, Mr Carter, for Village Maid; 4, Mr Holliday for Queen Victoria; 5, Mr Cheney, for Bellerophon 6, Mr Jenkins for Commander 7 Mr Perkins, for Ely's Mary *Red Feathered Heavy edge* 1 Mr Jacquest, for Martin's Prince George; Mr Weston, for the same, 3, Mr Jenkins, for Green's Adelaide; 4, Mr Carter, for Sharp's Duke of Wellington 5 Mr Bullock for Prince George 6, Mr Archer, for Duke of Wellington; 7, Mr Holliday, for Barraud's Cornelius; 8, Mr Hardwick for Duke of Wellington; and 9, Mr Perkins, for Prince George *Red Light edge* 1 Mr Bullock for Wood's William the Fourth 2, Mr Holliday for Holliday's Henrietta; 3, Mr. Carter, for Glidden's Fraser; 4 Mr Cheny, for a seedling, 5, Mr Archer for Wood's Queen Victoria 6, Mr Jenkins, for Teazer, 7, Mr Weston, for Weston's Surprise; 8 Mr Hardwick, for Sharp's Bloomer *Red Feathered edge* 1, Mr Archer, for Green's Adelaide; 2, Mr Holliday for Duke of Wellington; 3, Mr Perkins, for Martin's Grenadier 4 Mr Hardwick for Duke of Wellington; 5, Mr Jenkins for Martin's Ruler and 6, Mr. Carter, for Teazer *Purple Flakes, Heavy edges* 1, Mr Holliday, for Kirtland's Princess Augusta of Cambridge; 2, Mr Bullock, for Beetham's Princess Victoria; 3 Mr. Hardwick, for a seedling; 4, Mr Carter for Princess Victoria. *Purple, Light edge* 1, Mr Holliday for Ely's Grace Darling; 2, Mr. Carter, for Kirtland's Princess Victoria; and 3, Mr. Jacquest, for the same *Purple, Feathered edge* 1, Mr. Holliday, for Wilson's Flagstaff; 2, Mr Jenkins, for Sharp's Invincible; 3, Mr. Jacquest, for Dobbler's Juliet; 4, Mr. Hardwick, for a Seedling; 5, Mr. Weston, for Gill's Enchantress; and 6 Mr Bullock, for a Seedling. EXTRA PRIZES —*Pan of Scarlet and Crimson Bizarres* Mr. Holliday, with 2 of Harvey's Conqueror and 1 of Martin's Splendid scarlet Bizarre, and 2 of Mansley's Robert Burns, and 1 of Ely's Lord Milton's crimson Bizarre *Pan of Carnations* Mr Holliday, with Harvey's Conqueror scarlet Bizarre, Lord Milton crimson Bizarre Marquess of Granby, scarlet-feathered; Lady Ely, red feathered Evans's Queen Victoria, pink-feathered *Light-edge Picotee* Mr Archer, with Stinkler's Purple Perfection.

Reviews.

Spain and the Spaniards, in 1843. By Capt. S. Widdrington, R N, F.R.S. 2 vols, 8vo. Bosne

THE author of these volumes is already advantageously known by his "Sketches in Spain," published some years since—a work which gives us the only account of Spanish natural history which is to be found in modern English literature. When Captain Cook (now Widdrington) returned from Spain with accounts of new Pines, Oaks and other plants, to be found in a quarter of Europe so often visited by English, his statement excited no little surprise, and it was only by raising them from seeds and cultivating them in our gardens, that their existence, as new species, was satisfactorily established It was, therefore, with no small interest that we commenced the perusal of his new volumes, and we have not been disappointed.

When the learned professor of chemistry at Oxford volunteered to explore the localities in Spain where phosphorite was said to exist in such abundance as to offer an inexhaustible supply of phosphoric acid to our agriculturists Captain Widdrington agreed to accompany him The work before us is the result of that tour, extended through Navarre, the Castiles, Estremadura, Grenada, Leon, the Asturias, and Galicia, during which every opportunity of acquiring information regarding the social, political, artistical, and agricultural condition of the people was seized by one thoroughly acquainted with their language and customs

The phosphorite the great object of the journey, was found at a place called Logrosan, in the heart of Estremadura so far removed from the coast as to leave small hope of its being possible to export it profitably even if it were in great abundance But in fact the quantity appears to be inconsiderable compared with the reports that had been heard of its abundance

"The town of Logrosan stands upon and is chiefly built out of a mass of very hard and compact schist mostly black, with large veins of quartz The beds of this slate are nearly vertical, and run from S S W to N N E, being in fact part of the great system of Estremadura The vein or bed of phosphorite appeared to me to be conformable with these slates, and from observation at the junction near the road where it is best seen would appear to have been raised together with them at least I could come to no other conclusion It appeared to me quite independent of the granite and other formations, and to belong entirely to the slate The vein is of unknown depth, the quality improving as you descend, according to the accounts of the people, borne out by our own observations In general it is about six or seven feet in thickness, but in the lower division rather more, and also at the higher extremity appeared to widen very considerably It is, however, not pure throughout this width but passes into silex and some pieces were sufficiently hard to form flints before the introduction of percussion locks In some parts it has a rich leaden appearance, and I received a cut in my hand by a fragment, whilst working with the hammer quite as clean as if done with a knife. By the great kindness of Senor Luna we were allowed to dig or do what we liked and to carry away any quantity of the mineral Dr Daubeny might wish, with a view to the future analysis We accordingly determined to take four mule loads, each load or carga being calculated at eight arrobas, or 200 lbs, which quantity was put into two strong bags made of the coarse linen woven in all these towns From the specific weight being very great the cargas when made up had the appearance of lead or other heavy mineral The distance to Seville is about five days' journey and the contract was made to convey it at so much per carga, return of course included The terms were extravagantly high and quite out of the question for anything except experiment, but we had no remedy should any quantity ever be required, it must be sent by cars round by the high road of Merida

"After the requisite quantity had been quarried, which was soon done we selected the most pure samples for packing up, and although this appeared to be the best site for quarrying the mineral, at least one half was useless, from its being so siliceous The finer parts have a purple and white laminated and reniform structure like some depositions of carbonate of lime. It is extremely phosphorescent when pulverised and thrown on coals or charcoal and there is no doubt the accidental discovery of this circumstance, and its very different appearance from any of the adjacent rocks, originally led to the discovery of its existence in this remote and little-frequented district."

We regret that our limited space should prevent our making many extracts from this interesting work. We must, however find room for the author's account of a Spanish Oak —

"From the southern verge of the Serrania de Ronda, above Marbella, I have traced it, during my various tours, to the centre of the mountains of, Leon, almost to the water-shed of Asturias, and from the Alcaraz above Guadalaxara, to the western parts of the Sierra de Morena. The tree is seen, almost without exception, as scrub or copse, in which state vast tracts of it are to be met with in the wide region of its habitat. I have not the smallest doubt that the genus of this tree has furnished the Quercus humilis of the older botanists, whose works have, until quite recently, furnished the materials for the compilations called the Natural History of Spain. The foliage differs considerably in size and colour, as usual in copse, and this is another reason for its figuring under different names. It is a very beautiful deciduous tree, and when in health is second to none of the European species in appearance, and I have no doubt is hardy enough for our climate. The foliage is a dark shining green, the leaves of a sort of oval shape, and serrated; they vary in size from one inch in length, or less, to four inches; so much so that only a great deal of practice would enable any one to avoid confounding and splitting it into species. I suppose from the locality this is the tree figured by Boissier, as Q. Alpestris; which absurd name he proposed to confer on it, but the Quercus Quexigo would be far more appropriate, and his plate does not much resemble this tree, although he calls it Quexigo. The timber of the Quexigo is of good quality, but as they never grow together, there are no means of comparing its absolute value with that of the Q. robur. The bark of the large trees is corrugated much in the same way as that of the Encina. The elevation of the zone the two species inhabit is exactly similar, but I have not seen the Quexigo so low to the south as the congener, and I am not aware that it is found below the centre of the Sierra Morena, and the Serrania de Ronda. The medium height at which it is generally seen is from 2000 to 3000 feet above the level of the sea, although both in the mountains of Leon, and in the Serrania de Ronda, it attains a greater elevation. Wherever they are seen in juxtaposition, as in the Serrania de Guadalupe, and also in the Leon district, the species that is placed immediately above it is the Alcar, or Quercus toza, mentioned in my former work as forming a zone in the Guadarrama and S. Nevada. This is the woolly-leaved species so common in the Landes, and at the foot of the Pyrenees, and I believe also in the Bocage of La Vendee, the most northern habitat that I can quote belonging to it."

At Jaen Captain Widdrington found in the markets 'a round Pear, not to be distinguished in appearance from an Apple, of extremely good flavour." What can this be?

The following account of the bees of Estremadura is interesting. The case of the hiveless bees is new and curious: —"Bees abound in this district, and increase to such an extent that they return an enormous profit to those who take the trouble of looking after them. The common hive is the hollow stem of the Cork-tree, which is cut in lengths and is perhaps the best material in the world for the purpose, next to it is the common straw one used in England, both these substances have the same valuable quality of being non-conductors of heat and cold. They had never heard of such a thing, much less practised it, as killing bees, and were surprised when I mentioned such a custom. I ascertained a very curious fact in their economy that is well worth attending to A gentleman was mentioned in my former work as living near Casalla, whom I visited in his cortijo there, where he was farming the property he had purchased with his own fortune, from the Carthusian convent of Casalla, and which had been restored to it, without a farthing being reimbursed, by the orders consequent on the invasion of 1823. This is the Canon Cepero, so well known in the first Cortes at Cadiz, of which he was one of the most eloquent and distinguished members. After the death of Ferdinand he recovered his property, resuming his station as canon of Seville, and was living in the house of Murillo, where I paid him a visit. He told me that being shut up in the convent of the Cartuxa at Seville by order of Ferdinand after his return in 1814, a lot he shared with nearly all who had distinguished themselves in preserving the throne during the war of independence, by way of passing the time he applied himself to study the economy of bees, which he had followed up at Casalla, and was so successful in his management that in a very short time he had a thousand hives' When the civil war commenced circumstances' caused their being neglected and dispersed, and some swarms, finding no holes or cavities to suit them, attached themselves to a beam in an outhouse, where they made their combs in a similar manner to that by which the tree wasps suspend their curious fabric from the branches. They were so well satisfied with this novel situation that they never left it nor swarmed, but kept adding successive combs, until they nearly reached the ground, and hung from the point of suspension like a huge living and waxen stalactite. The owner never disturbed them, but had the lower combs cut off as they were wanted, and the colony had now remained for a considerable period, without their showing the least disposition to change it. This is certainly rather important information for the managers of apiaries, and may serve to confirm the statements lately published on the practicability of inducing the insect to work downwards."

Garden Memoranda.

Messrs Youell & Co, Yarmouth.—The conveyance from Norwich to Yarmouth by the railroad forms a very agreeable ride; the country being level, a passenger enjoys a sight of the surrounding scenery without interruption during his transit, from the "Ancient City" to the mouth of the Yare. In a recent visit to the former place, I was induced by this easy mode of conveyance to visit the establishment of the Messrs. Youell, to see their extensive collection of Carnations and Picotees. The stage alone is furnished with more than 200 pots, and double this quantity forms a reserve, which enables them to fill up the vacancies as they occur, by which the Exhibition is kept in good condition for a considerable

three. The stage on which these flowers are arranged would probably be more effective if divided into two; for in arranging so large a quantity for general effect, it is difficult to give the due preponderance to colour, without a much larger proportion of flakes and bizarres, compared to the number of Picotees. This assortment, like all good collections, is composed of the standard varieties, which have stood the test of years; with the fine sorts more recently introduced. In their growth the stems are rather short, but the flowers are full-sized and good in colour; the flakes are particularly fine; the bizarres partake of the fault of the season, that of being rather pouncy in the white. It is through this establishment that the Picotees raised by the Rev. I. Barroughes, an enthusiastic and successful cultivator of this favourite flower, find their way to the public. I noticed a new variety raised by this gentleman, named the Duke of Newcastle, a flower of first-rate properties; it is a light-edged purple; the petals are large and of good form and substance, even on the edge; the colour unbroken, the pod good, and with less disposition to burst than is common. Another new flower, named Mrs. Benyon, from the same source, apparently a fine variety, not sufficiently open to form a correct opinion of, and a new variety named Cook's Unique, red edge, with large stout petals and good crown, are two fine flowers which will soon find their stations in general collections. The Fuchsias here are numerous and well-grown. To a collection of the finest sorts in general cultivation, are added many seedlings of great merit of Messrs. Y.'s own raising, and from seedlings of the present year, three have been selected, which are handsome and distinct varieties—named Laconii, Elegans, and Eliabs; the last-mentioned variety has a very faint pink tube, sepals tipped with green, corolla deep blood-colour, and the flowers are a good size. Among the seedling Verbenas, a few distinct varieties have appeared—one named Leonora, a rich lilac purple, with a light eye, is a very bright and beautiful flower; Rose charmante, a brilliant rosy pink of a peculiar tint; British Queen, a large handsome lilac; and Hebe, a delicate grey; Vulcan, which is a very distinct flower, has the fault of curling back, and will, on this account, be less effective. In the grounds I noticed a very extensive collection of Araucaria imbricata, in fine health and condition; Abies Deodara, and young plants of Pinus gerardiana and excelsa. This memorandum was made from the town garden—the nursery is some distance from Yarmouth.—*F. H.*

Miscellaneous.

An Easy Way of Making the Seeds of the Cedar of Lebanon Germinate.—M. Leroy (A[illegible]), a nurseryman at Algiers, employs a much more simple and natural method of raising Cedar seeds than the common one. Instead of extracting the seeds from the cones, he plants these last entire in the soil; the seeds find in this condition a moisture suitable for their germination; they unfold themselves between the scales, of which many perish of themselves. It is easy then to remove them, for after-transplantation, either into beds, into the open ground, or into pots. This way is convenient for gardeners who are engaged in the multiplication of such trees; for it comes nearest to nature, and all the fertile seeds germinate. M. Pépin has presented to the Royal Society of Agriculture some seeds of a Cedar of Lebanon, gathered from a single tree, planted in the Garden of Plants in 1735, by Bernard de Jussieu. These seeds germinated last winter in their cones, while still attached to the tree; from the end of January every gale of wind blew down several. This premature germination was doubtless owing to the mildness and dampness of the winter. This was the first time that M. Pépin remarked this fact. The greatest part of the seeds were very much swelled, others had their radicle already extended, to the length of one or two inches. The winged membrane which accompanied the seed was generally adherent. Many hundreds of those seeds collected on the ground, have been sown in February, and are in as perfect a state of vegetation as those which have been since put into the ground.—*Revue Horticole.*

Cider; the Antiquity of its Use in Normandy.—The use of the fermented juice of Apples and Pears was known in the sixth century, and perhaps before, because since 587 St. Radegonde, Queen of France, drank perry (*piratium*) daily. The cultivation of the Apple and Pear tree must have been followed in Gaul, under the government of the Romans, who, as we know, took great interest in this cultivation. As to the art of extracting a fermented liquor from these two fruits, the exact time of its antiquity cannot be fixed, but it is at least certain that it was known to the Gauls and afterwards to the Franks, long before the arrival of the Normans. Indeed, in the eighth century, in the famous Capitulary of Villis, which repeats the views of Charlemagne upon the finances and administration of his dominions, is found a curious list of the different trades which he thought necessary to be in each of his great estates. This illustrious Prince ordered that they should contain persons who were able to brew beer and beverages made with Apples, Pears, and other fruits. Other records of the same period frequently mention the use of cider; and at the time of the fourth irruption of the men of the North, into Neustria, in 862, some authorities, not less respectable, speak of the alleys of Apple-trees which surrounded the ancient abbey of Fontenelle or Saint Wandrille, which these conquerors entirely destroyed. Hugues de Goernay, in the charter of the foundation of Ghis Ruissel, given to the monastery a right to one of his Argile orchards. We also see, in a record of 1183, that the Abbey of Jumiéges received a donation in Apples, sufficient to make enough cider for their consumption. There are numbers of charters as ancient, in which one of the principal duties that the monarch requires of his vassals is to gather his Apples to make his cider. I am indebted to M. Deville, the director of the Museum of Antiquities at Rouen, for the knowledge of a curious document respecting this subject. It relates a passage of a poem, written by the chaplain of Philip Augustus, William Lebreton, who had followed this Prince at the conquest of Normandy, in 1203—1204. This is what he says—

"Non tot in autumni rubet Algis tempore pomis
Unde liquare solet siceram sibi Neustria gratam;"

Algis is the province of Auge, and from *sicera*, an ancient Latin word, which signified all fermented liquors except wine, is derived our word *cidre*, which was then written *sidre*. Noel found that cider was among the goods which went up the Seine in 1315, and that in 1407 it was sold in Paris by wine-merchants. It appears very clear to me that we are not indebted either to the people of Navarre, Biscay, or to the Northmans, for introducing the cultivation of the Apple-tree into France, and for the art of brewing Apples. But I think it is equally certain that it was only towards the end of the 13th or 14th century that the use of cider became general in Normandy. Before that period beer, then known under the name of *cervoise*, was the common drink, even in those provinces which at the present time produce the most Apples. Many facts prove it. In towns and country villages there were brewhouses, some of which are known to have been very ancient, one of which was at Lillebonne. In 1358 there were brewhouses at Rouen. The acts of Dieppe mention beer, in speaking of the liquors which the fishermen took out with them to sea; and we know, besides, that there were very few religious houses which had not mash-tubs, boilers, and other utensils necessary for brewing this liquor. If, as we doubt not, Normandy possessed great numbers of vineyards before and during the middle ages, bear, and afterwards cider, counterbalanced at a very early period the use of wine, which has never been in our country anything more than a very indifferent drink. The cessation of the cultivation of the Vine has in my opinion been caused by the disforesting of our country, for the old and lofty forests protected the sides of the hills planted with Vines from the north winds, and consequently assisted in ripening the Grapes. In proportion as the forests of Normandy, which formed an extensive net-work, were felled, the quantity and quality of the wine decreasing every year, the inhabitants had recourse to other liquors, the preparation of which depended less upon the inclemency of the weather.—*Comptes Rendus.*

CALENDAR OF OPERATIONS
For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

After the middle of August—in dull weather—established stove plants should not be watered late in the afternoon; the dryer the stove is kept at night, through the autumn the better the plants will ripen their wood; and we all know that on the perfect maturity of each season's growth depend in a great measure the success of flowering and fruiting exotic plants: therefore allow the plants as much room as possible for the next three months. This cannot be too much insisted upon. An early vinery, where the leaves are all fallen, would be a good place into which to remove some of the stronger specimens from the stove for six weeks or so; here, with dry atmosphere, and plenty of air and light, they would ripen their wood perfectly, and the Vines would not be injured by the treatment.

Conservatory.—Those with fixed roofs and narrow pits attached outside for planting stove-climbers in, for furnishing the rafters, are now coming generally into use, and the experience of a few years will suggest further improvements in this way. "Devonian's" experience this season (p. 504) has proved what I have long asserted, that none of the hardy climbers should be allowed to run into the upper portion of a house having a fixed roof. Even the Mandevilla, which flowers equally well in the stove and in the open air against a conservatory wall, will succeed better in the lower part of such a house. There can be no question about the next best climber to suit "Devonian's" house without the aid of a stove pit: it is the Stephanotus floribundus. A plant of this that has not been more than eighteen months planted out in the conservatory here, is now a complete mass of bloom from top to bottom, and growing away as freely as a Passion-flower which is against the next pilaster. Echites suberecta was planted last spring, and it promises to rival the Stephanotus. I mention these things in order to keep people from planting out such climbers in a conservatory from this time till next April. A great step in furtherance of this mode of applying tender climbers would be to procure old plants, and train them on the rafters of a stove or vinery one season before they are removed to the borders of the conservatory, but where there is a pit at the back of the conservatory to receive them this precaution is not necessary.

Greenhouse and Pits.—Many of the more tender Heaths suffer much from wet autumns, and nurserymen turn these into pits or greenhouses about this time. Pits are by far the best places for such plants, as the glass can be put off and on as circumstances may require. Chrysanthemums and Violets must be well attended to from this time; give abundance of liquid manure to both, now that they are strong enough to make use of rich food. A plant or two of the Cactus truncatus might be put into the Gardenia frame, or into an empty Melon pit, with other plants requiring heat; they would flower sooner than the general stock, and a few of them might be kept back for succession.—*D. H.*

II.—FLOWER GARDEN AND SHRUBBERIES.
Out-door Department.

In addition to a proper preparation of the soil of flower-beds, it will also in another season be advisable to place more reliance upon Annuals for an early spring display; and consequently, a proper preparation must be made by sowing a general collection of the best kinds towards the middle of September. In the spring, I recommended the planting of beds thicker than usual: and accordingly, instead of allowing one plant to every square foot, as was the rule in former years, I planted two. The result, considering the season, has been satisfactory, my beds having been filled and in full bloom for the last six weeks; but then this has been attained by an expenditure of labour which not one gardener in fifty could command, and therefore, though the beds are full, there is no particular credit in the matter, as in ordinary seasons I have seen them quite as well stocked by the middle of June, and without much care to many plants. Now, in the coming season, I intend to plant three plants on every square foot, and instead of propagating and keeping the plants in the usual way, in stock-pots, I intend to strike three plants in a large 6s. pot, filling the pot half full of soil in the first outset, and then earthing the plants up as they advance in growth; thus our plants will be all autumn-potted; and though they may require more room for the winter, turf-pits are readily built, and, with proper attention, they preserve plants as well as can be desired. No amount of labour, however judiciously directed in the spring, can make up for time lost in the preparation of plants in the autumn. Those who have the best plants in November will have the best show of flowers next June.

Reserve-Garden.—Sow ten-week stocks immediately, under the protection of a hand-glass. Do not permit the young plants to become wet, or they will damp off. They are liable to mildew, but sulphur will check it.

Pits and Frames.—Proceed with the propagation of all bedding-out plants as expeditiously as possible, making choice of the more difficult ones first, such as Nierembergias, Lotuses, and the like. Leschenaultias for turning out next season should now be strong plants; give them another shift if they require it. Propagate scarlet, variegated, and common Pelargoniums as fast as you can get cuttings.—*W. F. A.*

IV.—PINERIES, VINERIES, &c.

Pineries.—Let the plants swelling their fruit be looked over twice or three times a week when the weather is hot, that they may receive no check for want of water. Dew the leaves over on the afternoon of every fine day. Much judgment should be exercised in watering the large successions during the next three months, as many of the pots are by this time so full of roots, that, if as much water were given to them as the roots would absorb, the result would be, by the commencement of winter, large and overgrown plants, which, however, would produce fruit of a very disproportionate size, owing to the plant having expended so much of its strength in the formation of leaves. Those who have given their larger successions the final shift will do well to prevent this overgrowth, by withholding, to a certain extent, the usual supply of water. The same effect may be produced by giving more air; but this would also check the growth of other plants in the same pit, which may rather require to be encouraged. If a pit heated with dung can be spared for growing the crowns and suckers in, it will suit them much better than putting them with the other plants in the larger pits. Prepare it by filling it with Oak-leaves, or partly-spent bark; apply but slight linings at first, to avoid having an undue degree of bottom-heat. Plunge the pots about two-thirds of their depth in a layer of tan, and shade till they become rooted.

Vineries.—Use great caution now to prevent moisture in houses where fruit is ripening, as it causes some of the thin-skinned kinds, as Muscadines and Sweetwaters, to crack. No pot-plants which require watering or syringing should be kept in the vineries with ripening fruit. Now is a good time to repair and paint, or make any necessary alterations in the early vineries. Vines in pots, when their leaves begin to fade, should be removed to the north side of a wall, and the pots laid on their sides, that the roots may be kept dry; a little litter may be laid over the pots, which will be of service to the roots, by preserving them from sudden changes.

Peach Houses.—In the late houses (the crop being now over) the trees will require to be watered and syringed with regularity. The lights should be open as much as possible to admit of a free circulation of air. After the crop is gathered, I find nothing better for clearing the trees of thrip and red spider, than applying soap leys to them with the engine.

Figs.—In fine weather too much air cannot be given where fruit is ripening. Supply the roots with water when necessary. For this no rule can be laid down, as much depends on the trees being in a state of luxuriant growth or otherwise, or on their being confined by walls. Those, whose roots are confined by walls (if bearing freely) will require occasionally a good watering with liquid manure.

Melons.—In dull weather the Melon plants will grow very fast, and will require strict attention to stopping and thinning. Give plenty of air, it will improve the flavour of the fruit. Withhold water when the fruit is ripening: a sudden supply of water at that time often causes the fruit to crack and become worthless.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Vines will now require much attention where there is a prospect of ripening the fruit. The bunches should receive their final thinning, and unless in the case of small sorts no more than one bunch should be left on a shoot. Remove all superfluous wood, in order to throw as much strength as possible into the fruit. If the spur system of pruning is adopted, leave as many shoots besides those in fruit as will be wanted next season; shorten bearing shoots one joint beyond the bunch, or to the joint at the fruit, provided the fruit is preserved, and one joint of lateral allowed to remain. Pick out a few of the buds at the axils of the leaves, towards the points of these shoots, that the buds at their base may be rendered more plump for next season. If the long or sure season rod system is followed no short shoots need be left that do not carry fruit, and these must be kept well shortened, so that by removing all useless growth and picking out the young buds in the axils of the leaves of such shoots, more strength and full exposure may be given to those long shoots you intend for bearing next year. Leaving a lateral with a leaf or two attached, has a tendency to strengthen the bud at its base, and prevents this bud bursting, if the shoot should be rather prematurely shortened; but some successful gardeners object altogether to the leaving of such laterals, considering that they render the buds three-cornered instead of plump and round. *Grafts* should now have their bandages loosened, and their shoots properly secured from winds.

Mildew.—See that it does not make its appearance on your wall trees. As a temporary remedy, nothing is preferable to flowers of sulphur. If merely the points of shoots become affected, cut them off at once. Some trees from their tender nature are very liable to its attacks, but in their case its ravages may be much modified, if not altogether removed, by paying attention to keeping the root and top of the tree in an equal state as respects temperature and moisture. Much knowledge may be gained respecting this troublesome enemy, by watching the circumstances in which it attacks the more common vegetables, as Peas, &c. *Onions.*—The remains of the autumn-sown Onions should now be got out of the ground as soon as possible. The same may be said of Shallots, Garlic, &c., as soon as their leaves decay. Spring-sown Onions may have their tops gently bent down with the head of a rake, to cause the bulbs to swell better. The sowing of seed to stand the winter, should proceed without delay upon cold stiff soils; on light soils, and warm situations, it will do a fortnight hence. No spring are better than the Strasburgh, or large White Spanish. *Celery.*—Prepare for earthing up the first general supply by removing all suckers and tying the plants neatly up. I earth up my first crops all at once, in a mass; in three weeks to a month before it is wanted. If earthed up at different times at this early season, many of the heads will run. We have had some for occasional use for more than a month. *Routine.*—Gather Herbs for drying. Plant out and hoe among winter crops. Clear Strawberry beds; make fresh plantations; sweep and roll the walks, and render the kitchen garden as much an object of interest as the pleasure-ground.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Put in, or glean the directions given in late Nos.

Coppice.—Attend to directions previously given for summer management in this department.

Young Plantations.—It is of great importance to keep the young plants and trees clear of all other stuff, cutting in, everything that overgrows or presses on them, or, that may injure their young and tender shoots. When too much shaded, young trees grow up tall and slender, and without a sufficient number

of side-branches. Remove or "shorten in" any very strong branches near the top that are likely to become rivals to the leader, or produce forks in the main stem; also "shorten in" any of the strongest side-branches, particularly where they are scanty, in order to increase the number of healthy shoots and leaves, for on this depends the increase of timber in the trunk.

Hedge-rows.—After boisterous winds the newly-planted trees should be examined, to see if they are firm at the root, and free from wind-waving.

Nursery Work.—The young plants will now be growing very fast; keep down weeds; train the young growing shoots of the present season in the proper direction.—*W. B.*

VII.—COTTAGERS' GARDENS.

As wasps are exceedingly numerous this season, protect by every possible means any fruit that is now approaching maturity. Among Plums, some recommend suspending bottles half filled with sour beer, honey and water, or any clammy liquid that will answer the purpose of entrapping them; and in favourable situations, where a Peach or Nectarine tree is cultivated, the fruit should be covered very thinly with wadding, as soon as there is the least appearance of any of them being injured. This, however, seldom happens before the fruit has attained its usual size and begun to colour. Collect any of the early sorts of Apples and Pears that are blown down, and lay them carefully aside on a dry floor or shelf. Let those that are bruised the most be placed by themselves and first taken for use. Continue to remove summer crops and prepare the ground for other vegetables. Those who are fond of Spinach may now sow a small quantity for autumn use. Where Parsley is much wanted and the spring-sown crop has either failed or is considered insufficient for a winter supply, an edging may be formed of the best curled sort, which will probably succeed better now than that sown in spring. The last sowing of Turnips for the season should also now be made, and a quantity of Vanack Cabbage may still be planted. This sort makes excellent spring Coleworts, and pushes fine sprouts from the stumps after it is cut. The last planting of Cauliflower and Broccoli had better now be got in. Tomatoes, if any, should be kept thin; cut out all useless shoots, and stop those retained at the first joint above the fruit. Keep Dahlias neatly tied up in order to prevent them from being broken by high winds, which are likely to prevail at this season. Trap Earwigs by placing inverted pots, having a little dry Moss in them, over the tops of the Dahlia stakes. In this way, by examining the pots frequently and killing the insects collected, these troublesome vermin may soon be got rid of. Stir up the surface of the ground among growing crops, and destroy weeds wherever they appear.—*J. M'H.*

State of the Weather near London for the week ending Aug. 9, 1845, as observed at the Horticultural Garden, Chiswick.

Notices to Correspondents.

Asparagus.—*A.*—The ground for the reception of your seedling Asparagus should be prepared before the plants begin to push in spring. It should be trenched 2½ feet deep, with at least 6 inches of rotten dung, or if the latter can be afforded a foot thick, so much the better. The ground should be trenched twice over, in order that the dung and soil may be thoroughly mixed. Plant in March, when the ground is in good working order, and rather dry than wet, in beds 4 feet wide, with 2 feet alleys between the beds. There should be three rows in each bed, the first a foot from the side, then a foot between each of the rows, will leave the third row likewise a foot from the other side of the bed; the plants may be a foot asunder in the rows, and covered over the crowns with fine soil, to the depth of about 2 inches. Some cultivators, French as well as English, prefer midsummer planting.‖

Bees.—*Undecided.*—You may introduce a little smoke from Tobacco, rag, &c. in the way you mention into the top hive. If that fail to dislodge the bees, you had better take off the hive, and fumigate them with puff ball, without disturbing those in the lower hive. Then put the apparently lifeless bees into an empty hive, and put it upon the top of the box; the bees will soon join those below. Except fumigation is often repeated, bees are not injured by it. *J. Wighton.*

Books.—*R. R.*—"Mills on the Cucumber." Sulphur is the only known *remedy* for red spider. A proper supply of moisture is the *preventive.*—*M. R.*—The first Latin grammar you can buy for 6*d.* on a book-stall, is as likely as any to answer your purpose. And add to it a Latin New Testament, which you can study by comparing it with an English one.—*A Constant Reader.*—Prof. Lindley has given up the idea of publishing a 2nd volume of his "Synopsis," now that the 5th volume of Smith's "British Flora" has appeared, with all the Cryptogamic plants fully treated of in it.

Cucumbers.—*Rus.*—A fruit 18 inches long, from the open border, without bottom-heat, and a handsome fruit too, is a remarkable specimen of good growth. Would it have happened in a season less hot than this?

Forest-trees.—*G.*—The following are quick growing, and will succeed, in an exposed situation: Quercus rubra, Turkey Oak, Ulmus vegeta, Alnus cordifolia, Acer pseudo platanus, Populus monilifera, Juglans nigra, Salix Russelliana and alba, Tilia europæa, and Sweet Chesnut.¶

Fruit-trees.—*G.*—*Cherries* for an orchard may consist chiefly of the following varieties:—Bigarreau, Bigarreau Napoléon, Büttner's Black Heart, Werder's Early Heart, Elton, Downton, Flemish, Florence, Knight's Early Black, May Duke, Morello. *Plums* for an orchard:—Royale Hâtive, Green Gage, Purple Gage, Coe's Golden Drop, Kirke's, Frotheringham, Washington, Ickworth, Imperatrice, Nectarine, Blue Perdrigon, Shropshire Damson, White Magnum Bonum, Early Orleans.‖

Fuchsias.—*T. J.*—It is very true that *F. cylindrica* has unisexual flowers; but our answer referred to the common species. We have never heard of a hybrid with that species, nor can we see what good is to be expected by crossing so poor a thing. It is very improbable that a Digitalis should be fertilised by a Gloxinia or a Lophospermum; but the latter is far more likely than the former. If you can throw a decided violet into the petticoats of the self varieties of Fuchsia, you will render beautiful what are now much less attractive than they were expected to be. Self Fuchsias will be driven out of cultivation.

Grafting.—*A Reader.*—You must be a good operator to make one-year-old Beech cuttings take, as we see that you do. But although you may have succeeded, and although others also succeed sometimes by using such wood, depend upon it two-year-old wood is what it is safest to employ. Ask the nurserymen.

Heating.—*No.* 2.—Dion is an idle fellow, and says that he will do no more than he has done:—"The idea is all that I proposed to give; others must use their heads and apply it. Any clever workman will understand the mode of executing such a plan." We confess we see no difficulty in setting in brickwork such apparatus as he proposes, and in making a chimney to carry off the smoke, or in supplying fuel. There is no sort of necessity to keep the water always boiling. Once heated it will retain its heat for a long time. If not set in brickwork there would be a great loss of heat; but the brickwork might be very slight.—*F. K. S.*—The apparatus will work, no doubt. You had better construct a close iron box for the fire-place; make on one side a door for draught, and by which ashes can be raked out, and from the other carry a small pipe into the open air. In such a contrivance you may burn charcoal or good coke, without inconvenience. In raking out the ashes pour water on them, and they will not be troublesome because of their dust. Gas stoves do not suit plants—at least we should fear not; they would contaminate the air too much. You may no doubt keep your boiler in action by a Camphine or other spirit lamp, but it would be an expensive process. If expense is no object, that would be the best way of heating the boiler.

Horticultural Society.—*D. A.*—We will lay your letter before the Exhibition Committee. We do not see how holding a meeting on a Saturday is breaking the *Christian* Sabbath.

Horticultural Society of Paris.—*M.*—Upon a full consideration of the question, we have resolved not to admit any discussion concerning the Royal Society of Horticulture. French disputes must be settled in French journals. We have no means of judging what truth there is in your statement that "the prizes are never given to *things* but to *persons*," and if we admit letters on one side we must on the other. If matters are conducted as you represent, why do not the members of the Société Royale de Horticulture take the course that would be followed in England, viz., join in removing the present managers, and in introducing others in whom they have more confidence?

Hydrangeas.—*Corylus.*—In the Index for 1843 are references to the paragraphs respecting the turning these plants blue.

Insects.—*J. Fox.*—The aphides infesting your Lettuce roots, are the Eriosoma lactucæ of Curtis. I have often seen them attacking the plants in July, but generally in neglected ground. Mixing unslaked lime with the soil in the seed-beds, and trenching the land in winter, would probably eradicate the disease. *R.*—*A Constant Reader in the North.*—The scales infesting your Vines appear to be the Coccus vitis. Clear away the old leaves as they fall in the autumn, and in February or March you must strip off the old bark and burn it directly. When this has been judiciously done I have seen the most beneficial results; indeed the Vine-scale has been completely eradicated. *R.*—*L. T.*—If your Melon-leaves are spotted by insects, it is at an earlier period of the year, for we can find none on them now. From their appearance we should attribute the disease to damp. *R.*—*London.*—As we could find no insects upon your Melon-leaves, owing to their not being inclosed in a box, it is impossible to say whether they are injured by the Thrips or Aphides. The former cannot be extirpated, it is said, from their being able to bear a very high temperature; but fumigation with Tobacco will destroy the latter. *R.*—*E. Q.*—The insects you complain of are Cheilifers, and are useful in destroying the Acari which infest frames. I wish, therefore, you would observe their habits minutely, and report upon the subject. *R.*—*N. O. P.*—We are much obliged for the larva; but it is totally different from the former one, and feeds upon Aphides. *R.*—*W. C. T.*—Your beautiful Fir-galls are figured in the 3d Vol. of this Journal, p. 630, and at p. 661 are some farther observations. There are *both* apterous and winged specimens, and some pupæ, but they are all the Chermes abietis of Linnæus. *R.*—*F. H. S.*—The insects destroying your Beans are an Aphis; but surely it is not the same species which infests your Dahlias. The best means of getting rid of them is to nip off the heads or leaves which are most infested, and destroy them at once; then syringe the plants with tobacco-water, or you may dip the shoots into the liquor, when it is very warm. The Ticks are called Ixodus Ricinus, and will attack man as well as animals. *R.*

Local Horticultural Societies.—*Arbroath.*—We shall be happy to prepare the printed forms we suggested, if we find any disposition to use them. At present, however, yours is the only application for them.—*C. M. C. H. S.*—As your observations were general, not personal, and made to serve the best interests of such societies, it is discreditable to the individuals you mention that they should have regarded your communication as offensive. This shows that your statement was correct, and that the judges in whom the ill feeling has arisen are unfit to hold their offices. Since you ask our opinion, we have no objection to say—1. That it is disgraceful in any man to judge his own productions, and suicidal in a society to permit him to do so; 2. That good feeling ought to prevent all communication between the judges and exhibitors, until after the Prizes are declared; and that if this is not attended to, nobody will believe the decision of the judges to be impartial. The last question we cannot answer; nor is it necessary that we should do so, because it is quite clear that if any society is managed in the way you describe, that society must go to the dogs.—*J. L. Dartmouth.*—You have not been named as the person complained of, and we cannot enter into local disputes, which must be settled on the spot. Our correspondent's letter was intended to show one of the causes of the failure of local Horticultural Societies, and his criticism was directed against the Society rather than any exhibitor. Even if we were disposed to publish your letter, its improper language would prevent us. If you are the person meant, and the plants were your own growth, you should satisfy the committee on that point—not us.

Mildew.—If *A Constant Subscriber* will tell us what he means by mildew in a hothouse, we will endeavour to suggest a remedy. If his leaves are mildewed, he had better send some by post.

Mulberry-trees.—*M.*—Pray get us the full particulars; we shall be much obliged. They should include, 1, the diameter of the head of the tree; 2, that of the earth heaped up; 3, that of the space built round the tree; 4, the nature of the soil.

Names of Fruits.—*A. P.*—Your Pear No. 71, is not the French Jargonelle; it is the Summer Portugal. No. 35 appears to be the Old Colmar, as far as can be judged from wood and leaves, in the absence of fruit. The Apple No 80, is the Kerry Pippin;—*J. F.*—Your Cherry appears to be the White Heart.‖

Names of Plants.—*H. Regius.*—Drimia lanceæfolia, not lanceolata.—*J. B.*—The plant which has so much excited your surprise is the common state of New Holland Acacias in their youth. The greater part of them produce common Mimosa leaves at first, and then exchange them by degrees for simple leaves, which eventually become their only foliage. What species you may have seen we cannot say; perhaps *A. melanoxylon.*—*W. F. G. F.*—Catasetum tridentatum.—*R. B. B.*—Sambucus racemosa.—*A. B.*—That variety of the common Ash which is called *F. heterophylla.*—*Tyro.*—Ipomœa sanguinea. There are two plants in the gardens, called Dendr. revolutum; yours is one of them; but whether they are species or only varieties we have not just now the means of deciding.—*J. C. L.*—1. Epidendrum inversum; 2. E. squalidum. We do not know a white Acropera.—*J. W.*—1, 3. Asplenium adiantum nigrum; 3. Asperula cynanchica.—*Pan.*—Chenopodium Bonus Henricus—perennial; a bad sort of Spinach.—*C. R. D.*—Crassula obliqua.—*A Subscriber.*—No. 1, Blechnum orientale; 2, Pteris, or Doryopteris pedata; 3, Doodia aspera; 4, Davallia elegans; 5, Pteris tremula; 6, Aspidium, or Polystichum coriaceum; 7, Platycerium, or Acrostichum alcicorne; 8, Doodia caudata: 9, Rondeletia speciosa.‖—*T. O. M.*—Maudevallia infracta. The determination of Exotic Compositæ is so difficult, that we really cannot undertake it.—*Henry Winch.*—Cyenoches pentadactylon.—*X. Y. Z.*—Hypericum Elodes.

Peach-trees.—*H. C.*—Your plants are attacked by red spider, for which you have no remedy except continual syringing. If the fruit was not so near ripeness adusting of sulphur would drive off your enemy. All you can now do is to wait till the fruit is gathered, and then apply sulphur. The dry, hot weather has been the cause of the evil. It is to be presumed that your Morello Cherries have their roots in undrained soil. If so, your obvious remedy is to plant them so high that the roots cannot reach it—unless you can drain the soil better.

Plants for Bedding-out.—*Isle of Wight.*—Procure the following, and increase them this autumn. Either of these will do for the centre, viz.:—Scarlet Pelargoniums, Fuchsias, or Pentstemon gentianoides coccineus. For the smaller beds take Petunia superba, Beauty, or splendens; Gaillardia picta, Œnothera Drummondii, Verbena atrosanguinea, Bishopii, Taglionii, Queen, and Lobelia azurea. These will all flower during the summer and autumn.¶

Trees, &c.—*Delta.*—If Delta be not a gardener by trade she cannot legally remove the trees or bushes mentioned by her. *W.*

Miscellaneous.—*A Lady.*—There is no better plan of destroying green-fly on Pelargoniums in a greenhouse than that of smoking the plants with Tobacco. Oleanders and Camellias are the best plants for a large Elizabethan hall, where there is a great draught in summer, and but little sun; but they will not flower under such circumstances. There is no evergreen creeper so good as Ivy for concealing a rustic bridge. For plants for bedding out in the flower-garden, see above. Besides Oaks, Heath or Thrift form a good border edging. In raising young Oaks the Acorns are sown either in autumn or spring. The cause of your Strawberries, which have been very prolific, drying up, and not ripening their fruit properly, is no doubt owing to the dryness of the season.‡—*J. Power.*—It is a bad practice to mow the leaves off your Strawberries. See p. 755, vol. for 1843.‡—*M. A. G.*—Cuttings of the new sorts of Calceolarias will strike quicker if you give them a little bottom-heat, but they will also do without it.‡—*A Kentish Man.*—Manor Farm, Deptford.—*Dot.*—A Wisteria sinensis, a small Tecoma radicans, and a small Laurestinus will not bear moving now. It is supposed that the ants feed upon the sugar secreted by the aphides, and the motions you have seen may well be supposed to be connected with the operation. There is nothing surprising in your hybrid Cactus having formed a stem 3 feet 6 inches high in six years, or in its flowering in a sitting-room. It, however, shows that you are a good and kind nurse, or it would not reward you with bloom 16 inches in circumference and 4½ inches in depth.—*W. A. L.*—If you can lay your pond dry, why not pull the Water-Lilies out of the mud? We cannot recommend you to salt (!) them. What is to become of the salt when the pond is again filled with water?—*L. B. M.*—All glaziers can supply glass. We never recommend tradesmen, for obvious reasons.—*J. B. W.*—It is very doubtful whether your seeds are worth sowing.—*J. H. H.*—We regret to say that your very careful description does not enable us to recognise the plant to which you allude. The points to which you attended are not such as botanists can use for the purpose of distinguishing plants. If you could give us *one* blossom, however shrivelled and old, we should probably tell you what your plant is. Your description shows that it was no Vitis; and that being the case the plant has little interest.—*W. D.*—Allow your young Fuchsias to remain in small pots through the winter. In spring, when they begin to grow, shift them into pots of a larger size, and encourage them as much as possible to form good plants early in the season.‡—*C. H. Hungerford.*—Ceropegia elegans is a well-known plant, and may be procured from any respectable nurseryman.‡—*J. N. Q.*—You had better plant against your wall, riders alternately with dwarfs, the former to be removed as soon as the latter become large enough to take their places.‡—*R. D.* not received.

SEEDLING FLOWERS.

Achimenes.—*J. C.*—Your Seedlings are pretty; but they bear too much resemblance to Rosea and the Old Coccinea. We can discover no trace of Longiflora in them.‡

Calceolarias.—*J. B.*—Your seedling is a fine bold flower, ground a rich yellow, with large blotches in the centre, and having a margin of smaller spots around the outline; good form.*

Fuchsias.—*Y. and Co.*—No. 2 is a large, bright, showy flower; tube and sepals carmine, corolla large, with a tinge of violet, foot-stalks very long. 3—Tube and sepals rosy pink; the latter are very long and narrow, and curl up in a peculiar manner, which is not agreeable; corolla long, of a rosy vermilion.*—*J. T.*—*No.* 1.—The sepals and corolla of this variety are too much alike in colour, and the latter want substance. 4, 5, 6, are three flowers of the same character, and too small; they are also not new—similar varieties are in cultivation. 14 has a bad corolla; 2 and 7 are too much alike, and possess no novelty; and 3, which is the largest and most showy in the collection, has too faded an appearance in the sepals.*—*S. B.*—The three dark varieties 4, 6, 7, possess no novelty; the difference between the colour of the corolla and the rest of the flower is so trifling, that their appearance is dull, compared with many of the fine sorts that are now generally cultivated. 8 is the best, being a stout, well-formed flower, but there is a deficiency of the violet colour in its corolla. 1, 2, and 9 are specimens of an opposite character; the tubes and sepals are of the most delicate pink, approaching to white, with the latter tipped with green. 3 is the best in form; 1 is rather larger; these have rosy vermilion corollas; 9 is a smaller flower of the same character, with a tinge of violet in the corolla.*

Pansies.—*R. R., N. B.*—No. 2 is the better seedling; it is flat, and the eye well marked. In No. 1 the markings on the edges of the lip and side-petals appear too much like stains; they both want the substance of first-rate flowers.*

Pelargoniums.—*W. M.*—The Guernsey seedling is a promising flower; rich and fine in colour, with petals of good form and substance. We should like to see it again when in condition.*—*P. P.*—The form of your seedling is not good, and we have many of the same colour very superior to it.*—*De Jonghe.*—Your box was opened as soon as it arrived; but not a flower was left. The contents had been so much shaken by the journey that all the petals had fallen, except from *ruscum eroticum*, which is a small flower of good form and substance, pleasing in colour, but requiring a white centre to increase its vivacity.—Foster's Favourite, Sultana, Nymph, Pulchellum, Lord Chancellor and Nestor, Garth's Queen Philippa, Witch and Unit, Hodge's Oberon, Lyne's Duke of Cornwall, and Beck's Susanna.*

Verbenas.—*W. G.*—No. 1 rosy red; the flowers of this variety are small, and it is not novel in colour. 2, rosy purple, with large, light eye; a good flower, but not new. 3 is an excellent variety, but its place is already occupied by Amethystina.*

SEED-WHEAT.—Any one desirous of purchasing Seed for next year is invited to inspect the two varieties of Wheat, SHIRREFF'S HOPETOUN and MORTON'S RED-STRAW WHITE, 120 acres of which are now growing on WHITFIELD FARM, THORNBURY, GLOUCESTERSHIRE.

The present is the only season of the year when the value of any variety of Wheat as Seed can be ascertained by inspection; for, if the examination of a mere sample of the grain, which can be seen at any time, be nearly uninstructive as to its quality in the eye of the baker (see *Ag. Gazette*, No. 5), it is entirely so as to the productiveness or habit of growth of the variety to which it belongs. These points, which are of the highest importance in the eye of the Farmer, can be ascertained only by an examination of the growing plant when in full ear. Price, 8s. per bushel. JOHN MORTON, Whitfield, Thornbury.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

WEDNESDAY, Aug. 14 Agricultural Society of England.
WEDNESDAY, Aug. 14 } Meeting at Dublin of the Agricultural
THURSDAY, Aug 15 } Imp. Soc. of Ireland.
WEDNESDAY, Aug. 21 Agricultural Society of England.
THURSDAY, Aug. 22 Agricultural Imp. Soc. of Ireland.
FARMERS' CLUBS.—Aug. 22 { Richmondshire. Grove Ferry.

IT is a matter of no slight advantage attendant on the weekly publication of an Agricultural Journal, that the attention of its readers may thus be called to subjects of importance at the most fitting times. It is not meant that agricultural topics are of temporary interest only; the operations of husbandry, which, taken together, form the business of the farmer, each of them exert a special influence on the great result—the quantity of net produce, or the money income of the farm. And thus there is not a single question connected with the practice or the science of Agriculture, which can *at any time* fail to be of interest; but while the farmer may reasonably have an eye to the future, and to subjects which may hereafter require his notice, his first and best attention will probably and justly be devoted to the consideration of questions of present interest. Certainly, therefore, we cannot at present direct our readers to the consideration of a more important subject than the PROPER PERIOD FOR REAPING WHEAT.

It would appear, at first, that the farmer cannot be wrong in allowing his grain-crops to attain maturity—to become fully ripe; ancient practice, so far as it goes, would certainly justify him in doing so. This, however, is not always a good guide to go by.

If by the period of maturity the time be meant when a plant has acquired its greatest value as an article of food, certainly this stage in the growth of every kind of crop ought to be attained before it is harvested; it is, however, by no means certain that maturity in this sense is not attained by our Corn crops at an early period in the process of ripening. Indeed it may safely be asserted that grain has passed the period of perfection and has begun to lose its value before it has become dead ripe. In support of this the testimony of all Nature may be urged that strength and vigour progress with growth only up to a certain period.

General reasoning, however, of this kind could never have been so influential with any farmer as to induce him to alter so important and time-sanctioned a practice as that of leaving grain to ripen thoroughly. And, practically speaking, the question remained undisturbed, and we were vain enough to fancy that at least we knew when our Wheat was ready to harvest, till Mr. J. Hannam, of North Deighton, near Wetherby, Yorkshire, in the "Quarterly Journal of Agriculture" for June, 1841, boldly asserted that the practice of allowing Wheat to become fully ripe was an injurious one. This assertion was based on the details of a careful and elaborate experiment made during the previous year, 1840. In 1841, Mr. Hannam continued his investigations on a still more extensive scale, and the results thoroughly corroborated his former conclusions. In September, 1842, the details were published in the "Quarterly Journal of Agriculture," and the question was discussed at length, the conclusion being that *the best period for cutting Wheat is when it is raw*, i. e. *from* 10 *to* 14 *days before it becomes thoroughly ripe.*

This decision has been since confirmed by the testimony of both Science and Practice. Professor Johnston in his Lectures quotes Mr. H.'s results, and confirms them by argument. He also states in his "Elements" (p. 188, 3d Edition), as "the result of theory and experience," that "about a fortnight before full ripening is the proper time of cutting Corn—as the skin is then thinner, the grain fuller, the bushel heavier, and the yield of flour greater." Mr. Stephens in his excellent "Book of the Farm," corroborates Mr. H.'s position. Indeed both the English and American Agricultural press have supplied numberless cases in support of his facts and arguments. To these our limits will not allow us to refer; we may, however, as testimony of peculiar value, name, that amongst the authorities who support the practice Mr. Hannam advocates are several of our Farmers' Clubs; those, for instance, of Leominster, Stewponey, and Wetherby, have each passed resolutions in favour of the early cutting of Wheat. On Thursday of last week it was resolved by the Wetherby Club, that it is advisable to cut Wheat at from 7 to 14 days earlier *than is customary in the district*. This Club is in Mr. Hannam's immediate neighbourhood, and its testimony is therefore peculiarly valuable. Such, then, being the case, we cannot do better at this time than call the attention of our readers to the subject, and direct them for a full statement of the case to Mr. Hannam's papers in the "Quarterly Journal." To such of our readers as have not the means of referring to the back Numbers of that periodical, the following epitome of that gentleman's researches will not be uninteresting.

Mr. Hannam's first experiment was executed in 1840. Three samples were cut viz. respectively:—

No. I.	Green	cut . .	Aug. 4, 1840
II.	Raw	,, . .	Aug. 18.
III.	Ripe	,, . .	Sept. 1.

These were thrashed and carried to market, when the following prices were put upon them:—

No. I.	61*s.* per quarter.
II.	64*s.* ,,
III.	62*s.* ,,

In 1841, a more extensive experiment was instituted; 5 samples of half-a-rood each were cut, viz.:

No. I.	Very green	Aug. 12.
II.	Green	Aug. 19.
III.	Raw	Aug. 26.
IV.	Raw	Aug. 30.
V.	Ripe	Sept. 9.

These samples were threshed, and the samples were as follow:—No. 5 (ripe) was "bold, but coarse;" Nos. 1 and 2 (green), "fine in the skin, but small;" and Nos. 3 and 4, "equal in boldness of grain to No. 5, and superior in clearness of skin," being "unexceptionable as a sample." This desiccation, or drying-in of Nos. 1 and 2 proved that it was taken too early. The whole of the samples were shown at the Annual Show of the Wetherby Agricultural Society, Sept. 22, 1841, when the superiority of the raw-cut grain was confirmed by the Judges, who awarded to it "an extra premium, with a high commendation of the sample No. 3, cut a fortnight before ripe."—*Yorkshire Gazette, Sept. 25, 1841.*

Having in one trial ascertained the value of the samples by market, and afterwards by the opinion of a public meeting, in order to leave no loophole for doubt, Mr. Hannam determined to test their qualities at the mill. The gross quantity of each was ground and dressed by Mr. John Hardcastle, of Wetherby; and from the results we compile the annexed tables:—

No.	Grain. Quantity	Grain. Weight.	Flour.	Pollard.	Bran.	Waste	Cut.
	bush.	st. lb.	st. lb.	st. lb.	st. lb.	lbs.	
III.	$3\frac{1}{4}$	15 10	12 6	0 12	2 1	5	Raw.
IV.	$3\frac{1}{16}$	16 6	12 3	1 3	2 5	9	Do.
V	3	14 13	10 11	1 9	2 5	2	Ripe.

No.	Weight per Bushel of Grain.	Flour.	Pollard.	Bran.
	lbs.	lbs.	lbs.	lbs.
III.	$62\frac{6}{7}$	$49\frac{5}{7}$	$3\frac{3}{7}$	$8\frac{3}{7}$
IV.	$62\frac{42}{59}$	$46\frac{48}{59}$	$4\frac{35}{59}$	$8\frac{56}{59}$
V.	$59\frac{3}{7}$	$43\frac{1}{7}$	$6\frac{1}{7}$	$9\frac{3}{7}$

No.	Weight per cent. of Grain.	Flour.	Pollard.	Bran.
	lbs.	lbs.	lbs.	lbs.
III.	100	$80\frac{1}{14}$	$5\frac{5}{14}$	$13\frac{1}{7}$
IV.	100	$74\frac{3}{59}$	$7\frac{1}{59}$	$14\frac{30}{59}$
V.	100	$72\frac{1}{14}$	$11\frac{3}{14}$	$15\frac{1}{14}$

"From this we see," says Mr. Hannam, "that the bushel of No. III. gives more flour than the bushel of No. V. by $6\frac{4}{7}$ lbs., showing a gain of $15\frac{1}{7}$ *per cent.* in weight of flour upon *equal measures* of grain."

Again, we find also that there is an advantage of "nearly 8 per cent. of flour in favour of No. III. *upon equal weights of Wheat.*"

The theory upon which Mr. Hannam explains these astonishing results is, that as the sugar in the green plant becomes changed into the starch of the Wheat, so if permitted to remain till fully ripe another change will take place, the starch becoming gradually converted into *woody fibre;* for it is a well known chemical fact, that sugar, starch, and fibre, are composed of the same constituent elements united in the same proportions, and are one and the same substance in various forms—in some such way as water, ice, and snow are different forms of one combination of oxygen and hydrogen.

This gradual change to woody fibre takes place in many vegetables as they ripen, and it is by taking this into account that we can explain the curious fact shown in the Tables that the ripe Wheat contains 50 *per cent. more* "*flinty* particles"—"pollard," or "sharps,"—than the "raw cut grain." Hence it is no wonder that the flour of the ripe should be less *free* in the grain.

Mr. Hannam also claims a "better quality of flour," for the raw cut grain, and quotes the analysis of Professor Johnston, to whom samples were sent, from which it appears (see Lectures, p. 734) that the

Raw Wheat contained	9·9	per cent. of gluten.
Ripe do.	do. 9 6	" "

The other advantages claimed for cutting early, are a better quality and greater quantity of straw, a better chance of securing the crop, &c.

The quantity, *i. e.* the weight of straw must, it is evident, be increased, and it is equally true that its quality is improved owing to there being more soluble matter in the *fresh* than in the *dry* straw. In fact, the additional weight of straw is nearly all an additional weight of nutritive matter, starch, sugar, &c. which would when dead ripe have become fibre; and therefore it is of great consequence to the value of the straw either as an article of food or as a manure. We have not space to allude to the other indirect advantages which Mr. Hannam claims for early reaping Wheat, nor can we follow his arguments or facts so fully as we would wish on the points alluded to: if, however, we have been able to give our readers an idea of the case as it now stands, or to draw their attention to the further investigation of the subject, we shall have done them good service.

In conclusion, we give Mr. Hannam's estimate, based on his experiments of the money value of an acre of the same Wheat cut *raw* and *ripe.*

No. III.	Cut a fortnight before ripe . .	£14	18	0
V.	Fully ripe	13	11	8

—*H.*

APPEARANCE OF THE CROPS.

COLLECTED BY E. J. LOWE, ESQ., OF HIGH FIELD HOUSE, LENTON, NOTTINGHAMSHIRE.

ON tracing the appearance of the crops over England, and part of Wales, I have attained the following general results, viz.:—Wheat is, without a single exception, an average; if it can be called better in one county than another I should say it must be so in Oxfordshire; from this shire I have had specimens of ears of Corn sent containing upwards of 80 grains in each head. Oats hardly appear in any county to have reached an average; it is very short on the straw, and the account of it from Northamptonshire is worse than anywhere else. Early sown Barley will be nearly an average, with the exception of Westmoreland, Northampton, and Wales, where it appears to be deficient. But owing to the long drought in every county many acres prepared for Barley were not sown at all; and, also owing to the same cause, many acres were sown in the middle of May and June, which have vegetated at twice, consequently the quality will be very inferior, as well as the yield remarkably bad. Hay is a worse crop than we have known it for some years, not being half an average in any part of England, except on irrigated lands. This crop has been a complete failure in Northumberland, Cumberland, Huntingdon, Hertfordshire, Gloucestershire, &c. Clover and Grass seeds seem to share the same fate with Hay, but perhaps not to such a great extent. Beans vary very much; they are bad in Lincolnshire, Rutlandshire, Northamptonshire and Surrey. Of Peas, the best reports are from Ruddington Grange, Nottinghamshire, and Caunic Donnington, Leicestershire, where the plants are thickly sown the ground and well podded; they are very bad in Kent, land and Kent. Potatoes seem to have suffered in most counties; indeed, from what remarks I have obtained, there cannot be nearly an average. Where the Potatoes are most grown they appear the worst, from dry-rot. The accounts from Westmoreland, Lancashire, Staffordshire, Worcestershire, Wales, and Shropshire make them a failure. The Potatoes look very healthy in Nottinghamshire. Turnips, in all probability, will be an average crop, although in some few instances they have been entirely destroyed by the fly. Fruit is very abundant all over England. For full remarks on the crops I refer you to the observations from different people from every county, commencing in the North of England.

NORTHUMBERLAND. — *Berwick-by-Wooler.*—"We had a remarkably fine winter, and the months of February and March were favourable, though stormy. March was very wet till about the 22d, when it set in dry, and continued so until May 9th; then we had two wet days. It rained also on the 17th and 19th, succeeded by dry weather. Rain occurred on 7th June, followed by high winds, amounting to a gale on the 13th; it rained on the 17th and 19th, since which it has been generally fine. The season on the whole has been very dry. Wheat looks very well; spring Wheat, though thin, looks well. Clover and seeds are bad. Barley has borne the cold dry weather better than might have been expected. Oats look promising, but very short on the straw. Turnips look very well, except the early sown varieties, which are very irregular. Pastures are bare, but green."—*J. C. Langlands.*

CUMBERLAND.—*Hurraby, Carlisle.*—"We have two kinds of land—strong clay-bottomed and light sandy. On the former, crops are good; on the latter they have been burnt up by the drought—(the former land prevails). Grass is very light on all lands; Wheat very good; Oats and Barley in most places good. Turnips promise well. Fruit very abundant."—*J. Atkinson.*

WESTMORELAND.—*Kirkby Thore.*—"Wheat looks remarkably well, and a greater breadth than usual has been sown. Barley is a slender crop, less than we have had it for some years. Oats are very short, and cannot possibly reach an average. Potatoes are greatly deficient, dry-rot being general; I have seldom seen such a falling off on all kinds of soil. Turnips promise well. Clover and sown Grass will not be more than one-third of a crop; this observation also applies to meadow Grass."—*J. Crosby.*

Bowness, near Kendal.—"The crops of every description in this hilly district appear to look better than in any other portion of England that I have lately travelled over. I have consulted the best practical agriculturist in the valleys (Mr. Ullock) on the subject; the following are his remarks:—Wheat is above an average; Oats are a fair, healthy crop, though rather short; Potatoes are abundant; Grass about three-fourths of a crop, of better quality than usual."—*Mark Beaufoy.*

Lancashire.—*Chaigeley, near Clitheroe.*—"The prevailing wind for the last two months has been north-west, which has done much injury to the crops. Hay is much later than usual, though I do not expect it to be below an average. Many of the fields have reservoirs for flooding, which makes them feel the want of rain less. Potatoes have suffered the most, many of the sets never having vegetated, from the effects of dry weather. Beans are shorter than usual, but look very promising. Pasture Grass is rather below the usual average."—*W. Winstanley.*

Woolton Lodge, Woolton, near Liverpool.—"The constant dry weather we have had for the last three months has made the Hay crop very scanty; the old meadows, except on flat and moist districts, will not yield one-third of a crop. We have had rain within the last seven or eight days, which has improved the promise of Corn. Oats and Barley will be well headed, though short on the straw. Wheat looks very well. Our neighbourhood is more occupied as dairy farms, and there is a great scarcity of Grass for the cows."—*Dr. Winstanley.*

Yorkshire.—*York.*—"Grain crops generally look well, especially Wheat. Beans are very short; Turnips promise well; Grass is generally about half that of last year, or less, especially in the calcareous districts of the East Riding. Potatoes seem likely to be a good crop."—*J. Backhouse.*

Hall Gate, Doncaster.—"In this neighbourhood, although there is much sand and gravelly soil, the crops have not suffered nearly so much as was apprehended. I never saw Wheat look better. Hay crops have been light, and in some places have completely failed. Barley looks fine, and other crops look well."—*J. Hawley.*

Caernarvonshire.—*Bryngybria, near Conway.*—"Owing to the continued dry weather, spring Corn and Grass have suffered much. Hay crops are very light; Grass is very much burnt up; Potatoes very irregular; Barley very bad and very short; Beans and Oats are very short; Wheat in general looks fair, but not heavy."—*J. Williams.*

Cheshire.—*Neston.*—Wheat is an average; there is very little Barley sown, but it looks well; Oats look poor; Hay is very light, and pasture-land is burnt up; early-sown Turnips look well; south of us Corn and Potatoes look better."—*W. Quay.*

Derbyshire.—*Ripley.*—"Owing to the continued dry weather, Oats and Barley will be below an average. Wheat looks remarkably well; Hay crop is very small. I was near Chesterfield a few days ago, and should say — Hay crop there is near an average."—*J. Royston.*

Edale, High Peak.—"The crops generally look well. Wheat and Barley are very good, but much must depend upon the weather for the next two months; we do not commence harvest until the end of Sept. beginning of Oct."—*S. Langworth.*

Nottinghamshire.—*Ruddington Grange.*—"I never saw the Wheat universally, and the Barley generally, more promising to yield well. Wheat always does well upon the new red sandstone formation in a dry spring; the straw is firm, and the grain appears well fed. Barley short, but good; Beans short in the straw; Peas exceedingly well podded; Clover, where not spring cut, is a fair crop, say 30 cwt. to the acre; meadows which are not irrigated are exceedingly deficient—not more than one-third of a crop; Mangold Wurzel looks well, and also Turnips."—*C. Paget.*

High Field House, Lenton.—"Grass seems to be the chief thing which has suffered by the long drought; the Hay crop will not reach half an average; Clover and seeds look rather better; Wheat looks very well, and also Barley, though the latter is rather short on the straw. Oats, I fear, will not reach an average, and will be very short; Beans had, a few weeks ago, the appearance of a wretched crop, but are vastly improved; Peas, I think, will not attain an average; Potatoes look wonderfully well, excepting when on the sandstone rock, which are not so promising. Turnips look well, though we have a few exceptions, some fields having been totally destroyed by the fly. The soil generally is a rich clay, but part is on a sandstone bottom; on the latter the crops have suffered much for the want of rain, for we had scarcely any in the months of April, May, and June. Fruit is very abundant."—*E. J. Lowe.*

Marston Grange, Retford.—"I do not consider the effects of the weather will be serious to the crops. Wheat appears very good and rather early. Spring-sown Corn has not such a good prospect."—*R. Houghtinean.*

Lincolnshire.—*Boston.*—"Crops are greatly improved by the late rains. Wheat will be an average; Oats and Beans deficient; Barley is not grown here; Potatoes fair crop. The meadows are very light."—*S. Veal.*

Shropshire.—*Whittington Rectory, near Oswestry.*—"The pastures are very bare, and Hay very deficient, being only one-third of the usual crop; Potatoes will not be half the usual crop; Turnips are very unpromising; much Oats and Barley are short, (the former 6 inches high on poor clay land); Wheat short but very clean and good. With respect to cattle much depends upon the weather for the next six months. Some farmers have mowed their Oats to give to their cattle; others have cut for them branches of trees. Ox cabbage are not grown to any extent, but there are complaints about them: my own are doing well. Fruit is very abundant. I anticipate great destruction amongst the bees next winter, for they are scarcely collecting any honey."—*C. A. A. Lloyd.*

Staffordshire.—*Forebrook Rectory, near Stone.*—"I find the last rain in April was on the 5th; wind in that month from N.W. to N.E.; thermometer from 40° to 46°, barometer from 29.400 to 29.800; no rain in May, and wind almost always N.E. to E. In June a slight shower on 24th, two hours' rain on 25th, and in July 24 hours' rain on 4th; wind in June and July being chiefly N.W. I have been in various parts of the country, but I see we are more favoured than other places, the land not being drained, and full of springs, which has suited this season; Wheat is thin but well headed, (straw about 3 feet 6 inches high); Oats average from 2 to 3ft. 6 inches high; Barley good (not much sown); Potatoes have failed generally; I have seen no Turnips—those sown in first week in May never came up till the rain in June, and then the fly took them; Clover does not average above 10 cwt. to 15 cwt. per acre; Hay and the meadow land, where it is not watered, is a burlesque upon Hay-making."—*J. Curtis.*

Leicestershire.—*Castle Donnington, (Rectory).*—"Hay and Grass have suffered very much from the dry weather; crop very small. Wheat is very good; Barley and Oats have suffered much from the dryness, but since the rain fell have much improved, probably the crop will be below an average; Peas and Beans look very well, except the latter in places, which look badly; these are observations on the hills which are red clay, of the new red sand-stone formation. With regard to the crops in the valley of the Trent, which is composed of gravel and alluvial soil, Wheat is better than average, excepting partial failures on the gravel; Hay and Grass very failing; Barley much improved and likely to be nearly an average; Oats less favourable; Peas good, Beans improving, but it is doubtful if they will reach an average."—*S. K. Simm.*

Charnwood Forest.—"The crops are rather late, though they look well on the whole. Wheat is rather thin, but will be an average. Oats are very short; Barley full of weeds; Hay-crops remarkably light. Turnips and Potatoes look well."—*E. J. Lowe.*

Rutland.—*Empingham.*—"The depth of rain fallen during the spring quarter was only 1.52 inches, which is not much more than half the quantity that fell in the corresponding quarter of the remarkable year 1826, and the mean temperature in the shade was 10° greater than the average of several years recorded by Luke Howard, Esq., in his 'Climate of London.' Wheat is a splendid crop, owing to the dry weather; Barley was very little sown—some was sown so late as 21st June; the crop is very thin, and the late rain has caused a second crop to spring up; there will not be above one-third of a crop, and the quality very inferior—on cold land the crop looks well; Oats look very well, but short; Beans and Peas fall short of an average; Tares the worst ever known."—*W. Fancourt.*

Herefordshire.—"Wheat is a very good crop; Barley a complete failure; the same may be said of the Hay crop; Oats are light."—*J. Walker, Worcester.*

Worcestershire.—*Honeybrooke House, Kidderminster.*—"The long dry weather has been most detrimental to the Hay crops, not having any rain worth notice from Good Friday till 2d July; the generality of the crop is not more than half a ton an acre, while last year they were able to procure more than one and a-half ton. The grain is better than could have been expected—I should think on the whole a fair crop. The Potatoes turn out very badly, and as this is a Potato country, the loss will be considerable."—*A. Talbot.*

Warwickshire.—38, *Waterloo-street, Birmingham.*—"The Grass crop has been almost universally a failure. One gentleman cut only six tons from 20 acres; even low lands have been barren of produce. Wheat is an average; Rye an average; Oats rather deficient—they equal about two-thirds of a good crop; Barley is still worse, not more than half a crop; Beans are worse still; between frost and drought they will not reach more than one-third of a good return; Turnips are promising."—*S. Wright, M. D.*

Northampton.—*Courteen Hall.*—"Wheat is an average, the heavy and deep soils making up any deficiency there may be in the light and sandy lands; Barley, Beans, and Oats, are no doubt a failure. Hay there is, literally speaking, none; Turnips look well."—*W. Grew.*

Huntingdonshire.—*Little Barford Rectory, St. Neots.*—"In my situation on the plastic clays, the Wheat is thin with a good head; Peas ditto; Tares and Mangold Wurzel almost a failure."—*J. Arlington.*

Cambridge.—*Ely.*—"Wheat is an average; Barley good on heavy land, but very bad and late on light soils; many fields have been drilled in since 25th June. Oats on the high lands are bad, but on the Fens it will prove a good crop; Peas, though short, are well-podded and full; Beans are much improved of late; Hay crop is very poor; 2d crop of Clover looks well; Turnips (as some farmers say) look patchy, being two crops—those up before the rains, and those since; but on the whole I think they look well."—*G. Archer.*

Observatory.—"Wheat crop fine; Barley has failed very much, owing to the continued dry weather in spring, preventing proper tillage. No Oats sown here; Hay very light."—*J. Glaisher.*

Norfolk.—*East Dereham.*—"An average harvest—the Corn not being injured by the drought."—*J. Felo.*

Pulham, Mardeston.—"We can anticipate a full average crop. Barley will be inferior, part of the seed having vegetated since the rains, so that the crops will come in at twice; early sown Barley is very good—on the whole we shall have three-quarters of an average; Oats better than Barley, but are very little grown. The rain came in time to save the Pea crop, which will be an average; Beans have suffered very severely by the drought, there will not be above half a crop."—*R. B. Harvey.*

Suffolk.—*Thwaite.*—"The recent effect of copious showers has wrought magic in our fields; the Corn, except on light soils, is looking exceedingly fine; finer Wheat I never saw."—*O. Whitlecraft.*

Essex.—*Kelvedon.*—"Wheat looks excellent; the yield will be eight bushels more per acre than last year. Barley, Oats, &c., were looking bad, but the late rains have made a wonderful difference. A few days since we had a heavy mildew, which I am afraid will do injury. I was lately through part of Suffolk and the crops look very well."—*W. Wiseman.*

Saffron-Walden.—"The effects of the weather have been to reduce the Hay crops to quarter the usual average; Oats and Barley bad, except that early sown; Beans and Peas very dwarf. Clover and Trefoil almost destroyed on the lighter soils; Wheat a good crop, except in gravelly soils. Since the rains Oats and Barley have greatly improved."—*T. Spurgin.*

Dunmow.—"Wheat a good crop, though short in some places; Barley on clay lands, and where early sown, exceedingly good. In the Ruthing district, doubtless there will be a full average. I have had brought to me an ear of Barley having eighteen kernels on each side, and some of twenty have been picked from the same piece. Peas, though not generally a large crop, yet greater than anticipated; Beans very bad; few Oats sown, but what are, look bad; Turnips looking well; Mangold Wurzel nearly a failure."—*A. Barfield.*

Kent.—*Sandwich.*—"Wheat generally very good; Barley light and thin; Oats an average; Peas a very short crop; Beans likely to improve, but not very abundant."—*W. H. Weekes.*

Sussex.—*Parham, Petworth.*—"If the weather prove favourable there will be an average crop of Wheat; the Lent Corn is far from being good; Oats, Peas, Beans, and Barley, are all defective. The Hay crop is very light, many farmers not gathering more than half a load per acre."—*J. Morton.*

Surrey.—*Godstone.*—"Dry weather commenced on 25th March and continued till 25th June, when we had a heavy storm followed by showery weather. Wheat, more than an average; early sown Barley very good, late sown quarter less than an average; Oats an average; Beans very indifferent, full of blight, never can be an average; Peas very good; Turnips look remarkably well."—*E. Steaming.*

Middlesex.—"Hay is far below average; Wheat generally fine; Oats and Barley thin and light; Turnips do well; Potatoes are not defective. Great abundance of fruit."—*W. H. White, Royal Adelaide Gallery, London.*

Hertfordshire.—*Redbourn.*—"Wheat, with few exceptions, is above an average; Barley very bad, one patch being in full ear, the next only just up; what little was sown early looks better (great deal sown from 19th to 21th June); Oats, where sown late, suffer like Barley, but from what I see there will be near an average. The meadow Grass and Clover, with very few exceptions, were quite burnt up, so much so, that in many places they could not, on our flinty land, be mown at all. The fly has made great ravages amongst the early sown Swedes, the ground was in a bad state for their reception, being in dry hard lumps; the later sown Swedes and Turnips are exceedingly promising; Vetches, except where early sown, are very bad, both for green food and for seeding; the cold wet weather in February and March seemed to perish mine, which were rather late and on strong lands. Peas below an average, and Beans average not more than 12 inches high."—*W. R. Burnham.*

Bedfordshire.—*Luton.*—"Wheat is very promising; Barley and Oats have suffered considerably on dry gravelly soil, but the late rains have done wonders towards restoring the early sown Barley; the late sown has, in many instances, not come up at all. Grass crop is very short; meadow Grass, in some instances, is not sufficiently abundant to pay for the labour of making; there are some good crops in damp situations, by river sides, &c."—*W. Phillips.*

Buckinghamshire.—*High Wycombe.*—"The distinguishing feature of the season, comprehending April, May, and June, has been extreme dryness. The rain fallen during the three months only 1·537 in.; the next least quantity which fell in the same three months during the last 21 years was 2·990 in., and that occurred in 1834. But in further proof of the dryness of this season, I may state that the least quantity of rain in any one April, in the long period before mentioned, was in 1840, viz. 0·325 in.; in May, 1813, 0·384 in., and in June, 1826, 0·787 in. These, if added together, will make 1·493 in. The quantities this year were, as follows:—April, 0·387 in.; May, 0·625 in.; June, 0·525 in.; added together, 1·537 in. From this you will see that the excess is only 0·043 in., when the driest months out of all that occurred in 21 years were taken. Wheat very fine and abundant; Barley and Oats very good—former better in quality than produce."—*J. G. Talam.*"

Oxfordshire.—*Henley-on-Thames.*—"On the Chiltern hills, which are chalk with more or less clay, Wheat looks very well. Around Henley the Wheat will be a very abundant crop, many ears producing four and five grains in each spikelet. I can collect many containing 80 grains in each; but these are soon after mere chaff. Early sown Oats and Barley are good, but the late sown

Barley will be very deficient; much of the seed has not come up. Grass crops are also very deficient; Potatoes very irregular."—*J. W. Jeston.*

Berkshire.—*Reading.*—"No rain from March 25th to May 21st; again a cessation till June 18th. Wheat looks very well. The drought injured the summer Corn very materially. A great deal of Barley was sown in June; between Reading and Henley there are many fine fields of Barley."—*H. H. Coverlade.*

Kingston Inn, near Abingdon.—"Rain for April, 0·17 in.; May, 0 25 in.; June, 1·42 in. On June 30th we had very heavy rain. Hay very scanty, good prospect of a second crop; Wheat excellent in quality, as well as quantity; early sown Barley an average; the later sown sprang up at twice, which will hinder an average; Oats look well, but are not much cultivated; Beans tall and free from fly—in fact very good; Peas considered a good crop; Turnips very good."—*A. Murdock.*

Wiltshire.—*Warminster.*—"Wheat very good; Barley and Oats deficient on light lands."—*H. Robertson.*

Gloucestershire.—*Hanham, near Bristol.*—"Wheat very good; Barley bad; Beans partially failed; Grass very bad (from 60 acres I shall not cut 15 tons); Swedes look well; Vetches ditto; Mangold Wurzel has not come up, though sown on 10th April."—*E. Burrell.*

Somersetshire.—*St. Saviour's, Bath.*—"The Wheat crop is looking very well; Potatoes very bad; and the Hay crop a total failure. We have not had nearly so much rain here as in other parts of England. Rain fallen from 1st Jan. to 30th June, 10·43 in.; fallen in the three months, April, May, and June, 1·32 in.; Max. thermometer on 23d June, 91°."—*C. Blathwayt.*

Dorsetshire.—*West Bucknowle, Corfe Castle.*—"As to the effects of the N.E.-parching winds, and want of rain on the crops, Wheat on strong and deep land looks well; Barley and Oats in general very bad, much but just appearing above ground, for want of moisture; Hay crop very bad; Turnips look well. The late rains have improved all vegetation."—*W. Vons.*

Devonshire.—*Plymouth.*—"With exception of frequent rain during last week or two, we have had none since beginning of April. There is a great deficiency in all green crops. Wheat looks very well, and Barley an average."—*R. Bishop.*

Devonport.—"Wheat, though short in straw, is good in the ear; Barley very thin; Hay lamentably bad."—*T. Lancaster.*

Chagford, near Exeter.—"The drought commenced and continued, with exception of one or two slight showers, through April, May, and June; and so severe were its effects that pasture and meadow land was never known so scorched and barren. The soil is rather variable, in some cases rich and loamy earth, but more generally of a light sandy nature, composed of disintegrated granite, of which rock the entire substratum consists, with considerable quantities of peat in many of the vales. We border on Dartmoor, at an elevation of about 500 feet from the sea. Wheat will reach an average of about 20 bushels per acre; Spring Wheat cannot reach an average, having suffered much by the drought; Barley is very bad, except where drilled very deep in the ground; Oats good; Hay a complete failure; and Turnips look very well."—*R. Berry.*

Cornwall.—*Stratton. Rectory.*—"The rain that fell in April, May, and June, was 2 30 in. The drought has been very injurious; the Hay is light in the extreme; early sown Barley and Oats promise well, but late sown are very bad; Wheat looks well: it is rather short on straw, but has a good head. The pasture lands look very bare and burnt up."—*J. S. King.*

FARM BUILDINGS AT TIPTREE-HALL FARM.

The yards are so placed as to be entirely sheltered from the east, north, and north-west winds, whilst they are quite open to the south and west for sunny warmth: it is presumed the heat absorbed by the brick-walls and buildings during the day will be retained for a portion of the night, so as to produce a warmer atmosphere in the yards. The farm and other yards are on a perfect level; they are underdrained every four yards with stones and a pipe—same as the land. All the drains (except the roof-drains) terminate in the manure-tank; so that not a pint of water that falls directly on the yards ever escapes, except into the tank. All the water that falls on the roofs is conveyed through pipes to the brook. The sheep-yards, the bullock and horse stables, are all paved perfectly smooth with hard yellow bricks, set in cement; so that no liquid manure is wasted. This arrangement admits of cleanliness, without waste, by occasional washings. The Straw for litter being cut into chaff, is applied where required, without waste. The manure-tank is bricked, and set in cement. We put into it the solid manure as made, turning the moist bottom upon the top, as occasion requires, to prevent too violent a degree of fermentation, and adding occasionally sulphuric acid in water, especially in the summer months, or an occasional layer of earth. In winter we have always sufficient moisture in the tank. As we pump out the liquid manure from the well, which is three feet deeper than the tank, no solid manure can enter, there being proper gratings to prevent it. We choose a wet day, when nothing can be done on the land, to turn over the manure in the tank—there being a slated roof over it which keeps the men dry. It faces the north; so that the sun cannot shine on it to evaporate the ammonia and strength of the manure. In the winter, when we have a superabundance of moisture, we pump the liquid manure into Cranskill's liquid manure-cart, which holds 200 gallons, and apply it to the pastures, young Wheats, or fallows; first fixing the ammonia where required with sulphuric acid, being governed as to dilution by the strength by the dryness or wetness of the weather. We find the tank-manure of extraordinary strength, as well as density, from subsidence by fermentation and pressure. When filled to four feet above the ground, it contains about 200 loads of solid manure.

Manure, that is dropped in the day, is removed the following morning in barrows to the tank, so as to preserve its efficacy. The piggeries, paved with flagstones, discharge their moisture into the manure-well. The stone water-tanks in the yards and house are all filled simultaneously by one pump over a tank, 14 feet deep, bricked, and set in cement; into which is brought a never-failing stream of pure spring water from the valley below. This water formerly spoiled some acres, and caused the bog: but now it answers a much better purpose. I do not like the usual custom of giving manure-water to horses and cattle, instead of to the land. I presume they are, like ourselves, all the better for drinking pure water, instead of filthy compounds. The pump also supplies our copper, on which fits a perforated iron vessel, capable of steaming six bushels of Potatoes or other matter. This vessel travels backwards and forwards with wheels on a small iron rail; and by a lever, is capable of being filled, emptied, or placed over the copper by a strong lad. The cart-lodge is so placed as to avoid sun, and we consider a weather-tight implement house essentially necessary.

The barn is 130 feet long, 30 feet wide, and rises 18 feet before it springs the roof. The horse-power that drives the threshing-machine occupies 30 feet square on the ground-floor, and about 30 feet more is occupied by the granary and chaff-house, over which is the threshing apparatus.

The unthreshed Corn being on both sides of, and near to the threshing-machine, economises time in removal. On this account, and the facility of doing work under cover in bad weather, I like plenty of barn-room. I do not see the necessity of a steam-engine, as we do our threshing, chaff-cutting, &c., when we can do nothing else. The threshing-machine is of six-horse power; but we throw it out of gear, and work the chaff-cutter or corn-mill with two horses. We cut thirty-two trusses per hour into chaff. A crane (cost 50*s.*) fixed on the top of the granary in the barn, enables one man and a lad to load the sacks of Corn with ease, dropping them into the cart or waggon.

The iron gutters and pipes to our roofs may be found fault with on account of the expense, but I really cannot see the utility or profit of the present custom, that is, putting good and costly manure on Straw, and then washing it all out again with tens of thousands of gallons of pure water off the roofs, taking especial care that it shall poison the horse-pond, and then run down to enrich some stranger's meadow at the first flood. I hope in fifty years' time the farmer who does this will be considered insane. The idea of a man's throwing away his manure with his left hand, and with his right paying money to bring it back again, all the way from Peru or Africa, seems too ludicrous for the nineteenth century.

So far as we have had experience, pigs, poultry, and horses, thrive uncommonly well in our yards and stables, and no doubt our cattle and sheep will do the same. All our horse-feed is cut for the manger. Even our Tares and green food are cut up with Straw.

We contemplate clipping our bullocks when stalled in the warm stables, taking it for granted that Nature provided their long winter coats for open fields, as a non-conductor of caloric, and that they never were intended for artificial confinement. The thermometer will regulate our ventilation. They will be groomed every morning, the same as horses. There is quite as much reason for removing from their skins the insensible perspiration, as for grooming a horse. Health depends on cleanliness, as much in an animal as in a human being. In a state of nature, they would rub against a tree or fence. Having no such opportunity in confinement, we must do it for them. Some butchers agree with me that farmers often spoil the mutton as well as the fleeces, by keeping them on too long. Besides, a long coat requires support all the winter, as well as any other part of the body.

As to a good house, why, if our farmers are to be men of education and capital (which I hope they will be when they get Agricultural Colleges), I do not see why for a few pounds extra per annum, they should be deprived of the comforts of a proper residence. As my substantial brick and slate buildings are thought to be in advance of the age, I hope those who find fault with them will consider they are intended for the next generation.

If board and thatch are so very durable and advantageous in farmeries, why not apply them to towns and cities? My own opinion is, those temporary erections indicate either poverty or miscalculation. If there is "philosophy in frying a pancake," why should there not be "an adaptation of means to the end" in planning and erecting farm buildings?

In conclusion, as some of my farming operations are on so very different a plan from the common routine of proceeding, I will allow my farming friends to laugh at, but not to condemn them, till they have had an opportunity of seeing whether they answer or not. Should they by chance succeed, I shall expect those who now enjoy the joke will have the good sense to follow the example set them. If they do not, I shall certainly take care to remind them that they ought so to do.—*J. J. Mechi*, 4, *Leadenhall street.*

ON MINERAL AND INORGANIC MANURES.
No. XXIII.

By Professor Charles Sprengel.

d. Ashes.—As the ashes of the different sorts of fuel, of the various woods and peats for instance, of brown and common coals, &c., are of a very diversified composition—*i. e.*, as one sort contains much of potash, and another none at all, and so on—it follows, that their value as manures will be very different. And this is a fact borne out by experience, as we know that the ashes of some sorts of timber are very useful, whilst those of some sorts of peat are useless. Several sorts of ashes, as they contain no substance which decomposes the humus or other ingredients of the soil, act merely as food for the crops, whilst others act as solvents, as well as by nourishing plants by their component parts. The latter are, therefore, superior manures, although the former also possess comparatively a great value. As the effects of the different sorts of ashes are so diversified, we shall treat of them separately.

a. Wood and Vegetable Ashes.—Wood and other vegetable ashes are used for manure either in their original state, or after they have been washed; but, as in the former they are always very expensive, they are generally used in the latter. The refuse ashes are procured from bleacheries, potash and soap-boiling factories, being there used for the making of ley and carbonate of potash. These are always mixed with lime, which is added to it in order to make a caustic ley. If we, therefore, consider that vegetable ashes are deprived by water, not only of the potash, but also of all salts easily soluble in water (although some slight portion may still remain in them), it will be evident that ashes in their original state will always act more powerfully than after they have been thus extracted. But as the mineral ingredients of ashes, not soluble in water, are also to be found in different proportions in the ashes of the different woods and other plants, it follows that one sort of extracted ashes will benefit vegetation more than another. We shall first investigate ashes in their natural state, and explain their action, which cannot be done without knowing their chemical ingredients, which will best determine their value as manures. It would take up too much space to treat of all sorts of ashes used in agriculture; some of the most commonly used will suffice for our purpose.

1. *Ashes of the Red Beech.*—100,000 parts consist of—

5,520	parts	of silica.
2,330	,,	alumina.
3,770	,,	oxide of iron.
3,850	,,	oxide of manganese.
25,000	,,	lime.
5,000	,,	magnesia.
22,110	,,	potash, partly combined with silica.
3,320	,,	soda.
7,640	,,	sulphuric acid, combined with potash and lime.
5,620	,,	phosphoric acid, combined with lime.
1,840	,,	chlorine, combined with sodium.
14,000	,,	carbonic acid, combined with potash.
100,000 parts.		

Fresh *Beech-wood* ashes contain always less carbonic acid than is here stated, as lime and magnesia will (if the ashes are exposed to the air) attract the carbonic acid, and combine into carbonic salts; whence it follows that the per centage of this substance will be different, if the same sort of ashes be examined in a fresh state and after being exposed to the air.

2. *Ashes of Oak.*—100,000 parts consist of—

26,947	parts	of silica.
8,140	,,	alumina, oxide of iron, oxide of manganese.
17,380	,,	lime.
1,442	,,	alumina.
16,200	,,	potash, partly combined with silica.
6,730	,,	soda, ditto.
3,365	,,	sulphuric acid, combined with potash and lime.
1,920	,,	phosphoric acid, combined with lime.
2,408	,,	chlorine, combined with sodium.
15,468	,,	carbonic acid, combined with potash, lime, and alumina.
100,000 parts.		

3. *Ashes of the Pine.*—100,000 parts consist of—

6,093	parts	of silica.
17,030	,,	alumina, oxide of iron, oxide of manganese.
23,182	,,	lime.
5,016	,,	magnesia.
2,198	,,	potash, partly united with silica.
2,220	,,	soda.
2,228	,,	sulphuric acid combined with lime.
2,748	,,	phosphoric acid, ditto.
2 300	,,	chloride of sodium.
36,485	,,	carbonates of lime, potash, and magnesia.
100,000 parts.		

Fresh wood ashes contain also very often sulphuret of potassium, sulphuret of calcium, and manganate of potash; the sulphurets form (by longer exposure to air) sulphates, whilst the manganate of potash is changed into carbonate of potash and oxide of manganese.

All sorts of ashes formed under a high degree of heat, contain somewhat less potash than those formed under a less intense heat, as the potash (potassium) is partly expelled, and this should be taken into account in purchasing ashes; the former will act also less powerfully, as the great heat will cause a vitrification of the potash with the silica.

Looking at the above analyses, therefore, it will be evident that the ashes of Beech must be the most powerful, as it is the richest in lime, alumina, potash, sulphuric

and phosphoric acids. Experience has confirmed this. If 1000 lbs. of fresh Beech ashes are brought on the Magdeburg acre of land, the soil will receive thereby 250 lbs. lime, 50 lbs. magnesia, 221 lbs. potash, 33 lbs. soda, 76 lbs. sulphuric acid, 56 lbs. phosphoric acid, and 18 lbs. chlorine, whence it will be seen that several crops will be thus provided with these mineral substances. It is equally obvious that an equal quantity of Pine ashes will produce a less effect, because if the acre is manured with 1000 lbs., this will amount only to 21 lbs. potash, 22 lbs. sulphuric acid, and 27 lbs. phosphoric acid. And although the amount of lime is nearly the same in Beech and Pine ashes, still potash and the sulphuric and phosphoric acids are the most important ingredients of fresh ashes. The ashes of Pine act, it is true, also in respect of its carbonate of lime decomposing the organic matter in the soil, but the same is done by the carbonate of lime of Beech ashes, which effect is there increased by the greater amount of carbonate of potash; the more so, as potash is a stronger basis than lime.

SUGGESTIONS RESPECTING TURNPIKE TOLLS.

When I first heard of the appointment, by Her Majesty, of Special Commissioners to inquire into the grievances of South Wales, the origin of which grievances, and the subsequent insurrectionary actions of the Rebeccaites, was the unreasonable number of turnpike gates, erected by various turnpike trusts, and the consequent exorbitant demand for tolls, it immediately occurred to me that a plan of a less objectionable character might be devised for raising money to keep the turnpike roads in proper repair; I have subsequently reflected much upon the subject, knowing that the grievance was not confined to South Wales alone, but extended over the major part of the kingdom. I anticipated a general measure would have been resorted to, but finding a Bill brought before Parliament, only embracing South Wales, I venture, without entering into matters of detail, to publish a brief statement of a scheme, which I forwarded to them on the 1st January last.

In the first place I would suggest that all toll-gates should be removed, with the exception of those in the immediate vicinity of towns, where they may be allowed to remain, together with the attached houses, and made available as ticket stations. These premises would be eligible residences for Police officers and their families, who could thereby officiate in a double capacity; by attending to their constabulary duties, and also by giving tickets to, or receiving tickets from, travellers, according to circumstances.

Secondly.—All persons travelling by horse, gig, carriage, &c., and the proprietors of mail or stage-coaches, waggons, vans, &c. to take out an annual licence according to mileage or other specific arrangement. But all horses, carts, waggons, &c., used for purposes of husbandry, or carrying lime, guano, or any other kind of manure to and from farms, (except for hire,) and also for carrying agricultural produce to market, to be totally exempt. Districts to be formed under the special direction of Government; in these it would be necessary to station efficient officers for receiving, quarterly, the moneys paid for the various descriptions of licences; which moneys are to be disposed of in the following manner: viz.—to pay the creditors of the turnpike trusts interest upon their various secured sums at the rate of 4 per cent. (or the whole debt may be funded by Government at 3 per cent.), and the surplus to be divided *pro rata* £ per mile, for keeping mail and coach roads in repair; and £ per mile for other turnpike roads.

Thirdly. The present Turnpike Commissioners to be Local Commissioners, under whose superintendence the mileage allowance is to be expended.

Fourthly. Highways to be kept in repair by the occupiers of houses and lands within the respective townships, hamlets, or districts in which such roads are situate; land owners to contribute of the sum required for general improvements.

Fifthly. Vested interests in toll-gates to be protected; and, if possible, purchased.

Those persons, therefore, who make use of private carriages or horses, such as commercial travellers, &c., must take out an annual licence for that purpose, and the owner or owners of every coach, waggon, van, or other carriage used for hire or profit, with the exception aforesaid, must take out an annual licence regulated according to the average number of miles travelled during the three preceding years. From a calculation made in accordance with the foregoing suggestions, I have deduced the following result: viz.—That after paying 4 per cent. upon the sums secured to the creditors of the turnpike trusts, reserving annually a large amount for a sinking fund, and an adequate sum for surveyors, as also to meet incidental expenses, there will be a sufficiency for keeping the turnpike roads in repair throughout England and Wales. Were the above circumstances taken into serious consideration, no one, I believe, would entertain a doubt of the superiority of the scheme over that at present in force; that is to say, receiving tolls once in about every five miles. It will also be admitted, I apprehend, that persons contributing to the maintenance of turnpike roads will not have to pay nearly so much as under the present system; and likewise the charges for repairs of gates, toll-houses, law charges, clerks' salaries, and other expenses will be saved; at the same time affording just protection and encouragement to the agriculturist.—*Morris Sayce, Kington.*

Home Correspondence.

Saving Corn in Damp Weather.—In the laboratory we are in the practice of drying materials which do not bear heat, by aid of substances having strong attraction for moisture; one of which, lime, being largely used in manure, might be employed for drying the Corn, at no other cost than the labour. If the rick be made hollow, with the grain turned inward, a sufficient quantity of fresh quicklime placed within, and then all placed in from bottom to top, and covered over to exclude the external air, the lime will rapidly dry the air within, which will as rapidly draw moisture from the Corn, and so continue until the Corn is dry, or the lime saturated. And as quicklime will absorb about one-third its weight of water, a ton of lime will take between 6 and 7 cwt. of water, and thus probably dry 6 or 7 tons of Corn and Straw; for all this water must come from the Corn, if the external air is well excluded, and the lime raised from the soil by a bed of stones, gravel, or Straw. The lime must not, of course, touch the Corn, and therefore room should be left for it to swell in slacking. If there be no practical impediment to this method, the farmer may be enabled to save his Corn in the most capricious seasons, without the mortification of seeing it sprouting in the ear, as it stands or lies on the ground. It must be received only as a suggestion, having never, to my knowledge, been tried on the large scale; but its success in the laboratory gives reason to hope for its efficacy in the field.—*J. Prideaux.*

Folding of Sheep, &c.—For the sake of giving additional employment to the surplus labour of my parish, I broke up last winter an old sheep-walk on the upper chalk. As I have laid out 1000*l.* in buildings on 150 acres, I am anxious to follow the most approved principle of cultivation, and particularly desire the assistance of a practical and scientific agriculturist to determine the best manner of consuming 80 acres of Turnips, which are now, despite of the dry season, full of promise. On my clay farm I consume all my Turnips, Mangold Wurzel, &c., in yards sheltered with sheds for the cattle and sheep. I follow this practice, from the very obvious reason that in wet weather it is impossible on heavy clay to consume the crops on the ground. But this impossibility does not apply to the hill (chalk) farm. The universal practice here is to fold the sheep on the Turnips during the winter. It is plain that the exposure to wintry weather must be very prejudicial to the sheep in respect of their fattening; but then it is maintained by the old school here, that the advantage of the treading of the sheep, and equal distribution of the dung and urine on the land, cannot be compensated by any other means. I beg, therefore, the help of your counsel on this point. Would you on a light, *i. e.* chalk soil, cart your Turnips, and consume them in the yard; or would you rather erect in each Turnip field temporary shelter, such as is described in an early Number of your *Gazette*? It is clear that one must set off the cost of carting the Turnips, &c. to the yards, and then the manure back to the fields, and the loss of an equal distribution of manure on the field at the time, against the gain which the sheep will make by shelter in wintry weather. This seems to be an important subject of deliberation, applicable to all soils where the treading of the sheep would not be injurious.—*A. Hunstable.* [It is very hazardous work, acting directly in opposition to the experience of a whole district. We have no experience of a chalk soil, but we cannot be far wrong in advising you not to dispense with the treading of your land by sheep, which the farmers on chalk soils say is essential, unless you substitute something of a similar kind, such as the use of Crosskill's Clod-crusher, on your Wheats, which will enable you to adopt the economical plan (as our experience justifies us in calling it) of feeding your Turnips in sheds. Your safest plan is to draw only a portion of your Turnips at first, and feed them in sheds. The experience of a year will indicate the proper course in future.]

Carts or Waggons for Harvest Purposes.—In reference to a late Leading Article on "Carts *versus* Waggons," I can say from the experience of the two past and present seasons, that carts for harvest work, *i. e.* Hannam's harvest carts, are far superior to waggons; I will enumerate some of their advantages:—1. The cost is much less; my carts cost me 15*l.* each—they are well made. 2. They answer better than Scotch carts with wings attached for harvest work. Having one of mine fitted with wings, (I use Scotch or Cumberland dung carts, similar to those in common use, except that I have an improved way of tipping), I can speak from experience on this subject. I had three of them carrying Hay from a field about 200 yards from my homestead, where the rick was building, and having, through curiosity, noted the time it occupied to load and send them home, I found one passed my window every fifteen minutes, *i. e.* four in an hour; they were good loads well tied on and raked down—one man was pitching and one loading. As to their merits in working against waggons, I was last harvest employed in carting some heavy Oats from a field 1¼ mile from the homestead where the rick was building, and I borrowed two waggons of my neighbour, which, with three harvest carts of my own, made in all five carts and waggons. I went to the field and timed the men, to satisfy myself which took the longest time to load—the carts or waggons, (this I did unknown to the men, and it should also be remembered that my men had a prejudice against the use of single horse-carts, especially for harvest work, having been always used to waggons), and I found the carts occupied one-fifth less time loading than the waggons, each carrying the same load. I can give you another instance:—My neighbour, who all along had laughed at my doing all my work with carts, was one day busy Wheat-sowing, and beginning, as I suppose, to think of economising his horse-labour, came to me to borrow my harvest carts; I lent them of course; the next day on asking him how he got on, he told me that he had done as much work, *i. e.* had carted as many Beans with my three harvest carts and three horses as he had done the day before with three waggons and seven horses; others may think this strange, I do not. Let us see what the horses had to do. Three harvest carts will weigh rather more than 21 cwt. *i. e.* 7 cwt. each. One waggon weighs about 21 cwt.—as much as three carts; the Beans were on wet land ploughed into 8-feet ridges, with deep furrows; therefore the hind and fore wheels of the waggon must have been each in the bottom of a furrow or nearly so, in crossing the lands, and it would require a greater force to pull four wheels over two ridges than a cart over one with equal loads, for the waggon must be crossing two ridges at once. Then there is time saved in turning carts; one horse also moves much quicker than three can be moved together. Let a man once try them, and I think he would scarcely be induced to go back to waggons again, on any consideration.—*I. E.*

Liquid Manure.—For several months past many of your correspondents have dwelt voluminously on this subject: in fact, so much so, that it has become the engrossing theme of your Paper; and it is right that its merits should be discussed and made known; but it is too absurd to imagine that such wonderful results are to follow the application of liquid manure to land, as some of your able writers have described. I have a large cistern, a pump, and a liquid manure cart—all that is needful for going to work on a large scale. I have tried it on Grass lands, fallow for Potatoes, Wheat and Beans. I have applied gypsum with the same at the rate of from two to three cwt. per acre, but I have not yet perceived any very wonderful or astonishing results, although I have used it in wet weather, in dry weather, in spring, summer, autumn, and winter. It has proved useful, and done some good, and I do not wish to discourage the purchasing of pumps, carts, the sinking of wells, &c., &c.; only I would recommend that some of our most sanguine liquid manure men would be a little more moderate in their praises until evident results have been witnessed. It is *my* humble opinion that it would be far better, and more economical, to put burnt soil, turf, or road-scrapings, a foot thick, at the bottom of our farm yards, early in the autumn, to absorb the same, than to be at the expense and trouble of conveying it in carts from the cistern. It requires two horses to convey two hogsheads to the land when the ground is at all wet, and especially should the distance be far, it is a very serious expense. It is my invariable custom to put my store sheep into yards during the winter months. Last winter I had the bottom of one of the sheep yards covered with soil. It absorbed the moisture, kept the yard dry, and my sheep were remarkably healthy, free from foot-rot, and never wintered better. In turning the soil up with the manure in the spring, I found it thoroughly impregnated with the urine from the sheep. I should imagine that one cart-load of the said soil contained a very great quantity of the very best liquid manure. The expense of conveying it to the land has been considerably less than taking it from the cistern; besides I had an opportunity of putting the whole on my Turnip land at a seasonable time, whereas I could not have saved it in my cistern for the same purpose, as no place would have been large enough to have contained it. With all due deference to the opinions of the tank men, I would advise a trial of this plan previously to making cisterns, purchasing pumps, carts, &c., as I am of opinion it is the best way of securing the liquid manure, and by far the least expensive in conveying it to the land. In conclusion, I would beg my brother farmers to well digest the sage advice given by the noble President of the Royal Agricultural Society, at the late dinner at Southampton:—"Try cautiously those things which are likely to succeed, and do not expend large sums of money in things which you do not know whether they will succeed or not. If you find your experiments succeed, then go into the matter gallantly and well." So say I.—*Henry Hudson, jun., Wick, near Pershore, Worcestershire.*

Proper time to harvest Wheat.—I have to suggest, for the consideration of some of your correspondents—from whom I hope to hear through you upon the subject—the following considerations with reference to the ripening of grain crops. If a plant of Wheat be examined some two or three weeks before ripe, it will be found that the lowest joint, or perhaps the two lowest joints, are already yellow, ripe, and dead. The upper part of the straw—the ear and grain—are, however, still green and juicy. Now what I have to suggest is, that as the only connexion between the plant and the ground is useless for the conveyance of nourishment, and as the leaves, the only connexion between the plant and the air, may also by that time be considered as nearly useless and dead, the plant—straw and grain—must contain *then* all the nourishing material which it ever can acquire, however long it may be allowed to stand, to whatever stage in the process of ripening it may be allowed to reach before it is cut down. If this be so, the inference naturally follows that grain may be cut greener than is the general practice. And possibly in late districts, when the grain has been cut altogether green, the increased value of the crop (Oats for instance) as fodder, from this circumstance, may partly compensate for the loss which the farmer has sustained in losing a crop of grain.—*M. S.*

Steeping of Seeds.—I shall be happy to communicate the results of my experience in steeping seeds, when the proper time arrives for doing so, in the hope that I shall receive more valuable information in return. In the meantime I may safely state what may now be held as fact. The Corn steeped is taller than Corn not steeped,

growing side by side with it; it is also of a different colour, being of a lighter green. These remarks are true of Oats and Barley; Wheat steeped is taller, but of a darker green, and apparently later than Wheat unsteeped. Different steeps give different colours to the growing crop; thus, a steeping in nitrate of soda alone gives a darker green, and greater luxuriance than a steep compound of nitrate of soda and guano. We, in this part of the country (South of Scotland), are very much infested with black and useless ears in our crops of Oats and Barley this season. On the steeped portions of the fields there are fewer black ears; very few comparatively where the steeped seed was dried with lime, but a great many more where it was dried with soot alone. As soot is much of the same nature as charcoal dust, I do not attach much value to your recommendation to try this latter substance. Half a bushel of Oats were steeped for 24 hours in a pretty strong solution of bones and sulphuric acid (one by weight of the last to two of the first, with an equal weight of water). The Oats were sown moist and warm; black ears are rarely to be found where these were sown, while the ridges on each side are so full of them that if you walk through them you will be made as black as a sweep. My steeps consisted chiefly of guano and nitrate of soda; my rule was to give 1 lb. of each to a bushel of grain; but it was not strictly adhered to—generally exceeded, I believe. I seldom steeped longer than 48 hours, but I have reason to believe that steeping for a longer period will increase the fertility of the seed, although at the risk of injuring the vital power of it. What strength would you consider as the right strength of a solution in which Wheat is to be steeped 60 hours? Would sulphuric acid weakened with water, and thrown upon a heap of seeds, newly taken out of a steep, and afterwards mixed with lime, have the effect of forwarding or retarding the drying of the grain? I find that sulphuric acid, in strong solutions, has the effect of retarding the drying of the seeds.—*A Susbcriber.* [Your first question can only be answered by an experience which we do not possess. With regard to the second, we should certainly say the throwing of sulphuric acid of any dilution must be a very hazardous operation. If the acid be present in sufficient strength it would altogether destroy the texture of the seed.]

Bark of Trees.—Your inquiry about protecting trees from being barked by cows is answered by stating that the dung of dogs—Album græcum of chemists—mixed with lime as a wash, and applied to the trees, will prove effectual against all animals, sheep, hares, rabbits, horses, and cows. It may be coloured by soot, to take off the glare of the lime.—*X.*

Turnip sowing.—The following particulars are much at your service, should you think them worth a place in the *Gazette*; their publication may possibly prevent other parties falling into the same unpleasant predicament with myself. Owing to the very dry state of the ground I took unusual pains this season with my Turnip sowing: I procured the best varieties from an eminent London firm; I procured a box of Campbell's mixture to make a fertilising steep; and I prepared my manures in the most approved manner; besides all this my ground was in excellent order; and yet at this moment I have scarcely a single plant in three fields. I attribute this total failure entirely to the use of Campbell's steep. I have come to this conclusion from the following circumstance: I gave some of the steep to a tenant occupying a neighbouring farm, requesting him to immerse a small portion of his seed, and sow with it two bands in the middle of his field, which he did. These two bands now show a complete failure, whilst the rest of the field is covered with strong healthy plants; the entire field was drilled on the same day, and all circumstances similar, excepting the steep. Mr. Campbell's instructions were minutely followed, the seed being steeped 12 hours, and dried immediately afterwards in a current of air. The following are the particulars of sowing, &c:—No. 1. Sown in May with Laing's improved Swede: manured with a mixture of bone-dust, woollen waste, and liquid manure from the farm-yard, the whole mixed a fortnight before using, and in fine order. No. 2. Sown early in June with Dale's hybrid Swede; one-third of this plot manured with ashes and cloacine, the remainder with a mixture of farm-yard dung, woollen waste, and liquid manure, well mixed and in fine order. No. 3. Sown early in July with Gibbs's white Globe; manured with rotten farm-yard dung. In the middle of June, no plants having appeared in No. 1, it was resown, the seed steeped as before; there is now (July 25th) scarcely a plant in any of the lots, although there has been abundance of delightful rain. I am now sowing Nos. 1 and 3 with white Globe and red Norfolk, the seed unsteeped: No. 2 will be sown with Wheat in September. I am greatly disappointed, as you may suppose, and know not what will become of my cattle next winter, the hay crop being also deficient. In case of need I send you my name and address.—*E. R.*

Societies.

AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

At the Weekly Meeting of the Council on August 1, the following programme of the proceedings for the great meeting was agreed to:—The business of the Council was divided into two departments, namely, the show-yard department, and the distribution of tickets; the first of which would be transferred to the Horse Bazaar, Stephen's Green, on and after Monday the 12th of August next, while the managing committee would meet at the Society's Rooms in Sackville-street, and sit constantly from day to day, for the general dispatch of business. It was ordered—That the entrance tickets for stock into the show-yard, should be distributed by the clerk of the yard, at the Horse Bazaar, Stephen's Green, on and after Monday, the 12th inst.; and that all the tickets for admission to the different entertainments should be distributed at the Society's Rooms in Sackville-street, on the same days respectively. From the great increase of new members, and the demand for tickets, it was found advisable to confide the issue of them still to Members of the Society, Subscribers to the Local Fund, and Strangers from England and Scotland; but, that, in the meantime, every facility would be given to enable persons anxious to participate in the proceedings of the meeting to become Members of the Society, for the purpose. The Council then adjourned until the next week.

FARMERS' CLUBS.

Maidstone.—At the monthly meeting of this Club, the subject for consideration was The Comparative Advantage of Large and Small Farms. The discussion was introduced by the reading of some sound and excellent remarks on this subject from the first chapter of "British Husbandry," and a very interesting conversation ensued. On the part of small farms it was argued that they admitted of much closer attention being given to minute details, and that as the profit of farming mainly depended on small saving, the small farmers were most productive. In support of this view, the happy state of the people in Germany, Norway, and Switzerland, where the farms are all small, and worked by their owners and their families, was compared with the pauperised state of the population in Suffolk, Norfolk, and Yorkshire, where the system of large farms prevailed. It was also contended that as the small farms thus provided livelihood for a greater number of families, they were more advantageous both to the individuals holding them and to the nation. On the other hand, it was argued that the happiness of the small farmers alluded to arose probably more from their own provident habits than from the size of their farms; and it was added that in many of those countries mentioned, in Switzerland, for instance, the population was stationary, or nearly so, whilst the Irish small farmers, who were celebrated for their early marriages and improvident habits, were amongst the most destitute people in the world. An instance was mentioned in which a gentleman of large landed property, who imagined that small holdings produced most public happiness, pulled down his large farm houses, and laid out his property in small farms of from sixty to eighty acres. He soon found tenants, who went on well enough for the first year or so, as they employed no labour beyond that of their own families; and at times wanted employment to fill up their own time. This they could not get, as they were all small farmers together, neither of whom had capital to employ any one, and each wanted to be employed. The result was that in a year or two every one of these tenants gave up his small holding, and the landlord laid his estate out again in large farms. It was stated that the race of small farmers with small capital, who might be considered half farmers and half labourers, were least disposed, both from want of means and information, to adopt any improvements; they were always compelled both to buy and sell at a disadvantage; that in every period of agricultural pressure they were invariably the first to suffer; and it very frequently happened that themselves and their families, if they were not employed as labourers by the large farmers who succeeded them, were at last reduced to the union house. Such cases had repeatedly occurred under the old poor law. In the earlier part of the discussion it seemed to be generally imagined that the small farmers gave a larger amount of employment in the aggregate than the large ones, but so many instances were adduced where the reverse was the case in whole parishes, that it was ultimately the opinion that the large farmers gave the most. Even supposing, however, that three times the amount of produce was raised on a farm of 300 acres, than was raised on three farms of 100 acres each, it was still contended that it was for the benefit of the community, as well as of the farmer, that the largest possible amount of produce should be raised from a given space of land, with the smallest possible cost. It was admitted to be almost invariably the case that the small farmers only turned off their men during the winter, whilst the larger capitalists almost always found them some profitable employment. It was admitted that, from the comparative deficiency of supervision, the large farmer seldom got so much work out of his labourers as the small one, who generally also got more out of the dairy, piggery, and poultry; but it was believed that those advantages were more than compensated for by the great advantages of capital, which enabled the large farmer to adopt a uniform system, to purchase the best implements and machines, and to apply, in catching seasons, a large amount of force to any given operation. The following resolution was ultimately agreed to:—"Resolved, That it appears to the members of this Club, that in this district it is most beneficial to the community at large that arable farms should not exceed 500 acres in extent, nor be less than 250 acres."

Darlington.—At the monthly meeting of this Club, held on Monday last, the subject under discussion was, The best Method of Making and Securing Hay; also The best Season of the Year for applying Manure to Grass Land. Henry Chapman, Esq., the chairman, introduced the subjects, and read an interesting paper thereon from the pen of Mr. Davidson, a regular correspondent of the Club. During the discussion which ensued, it seemed to be the general opinion of the members present that, in fine sunny weather, experience has already taught us nearly all that is requisite to be done in making and securing Hay to advantage; but that, under all circumstances, even in the finest weather, it is desirable to keep the Hay in such a state of security that, should a change of weather take place, no considerable injury may be sustained; it is also an important matter to economise labour as much as possible, for which purpose the Hay-making machine may be used to great advantage in dry weather. In a wet season it was considered best not to have too great a quantity of Grass cut at one time, and to allow the Grass when cut to remain in swathe for some days, should the weather continue wet, occasionally turning the swathes; but when the Grass has been spread, it is desirable to have it put up into small cocks, or lap-cocks, as soon as possible, opening the cocks out during the dry part of the succeeding days, but never opening out more in one day than can be put up again in the same day, or before rain comes on, and increasing the size of the cocks as the Hay dries. The Hay-machine should be sparingly used in damp weather, as it beats out the seeds of the Hay too much; it was also believed to have an injurious tendency by the wheels running over the Hay, and pressing it upon the damp ground. When Hay has got a good deal of weather in the harvesting, it was recommended to mix about a peck of salt with each ton of Hay in the stacking, providing the Hay be tolerably dry when stacked, salt being known to improve the flavour and quality of Hay very materially that has suffered from the weather. In discussing the best season of the year for applying manure to Grass lands, there were some members present of opinion that there was no need to manure Grass land at all, and that, by pasturing it frequently, it might be kept in condition, and the manure more profitably employed upon the tillage land of a farm; yet the majority were decidedly in favour of applying manure to Grass land, believing that, by judicious management, it might occasionally be quite as profitably applied to Grass land as to tillage; and the unanimous opinion was, that the best season for applying the manure is immediately after the Hay is taken off the land, as the manure at that time gets free access to the roots of the Grass; besides, Grass newly cut generally grows rapidly, by which means the manure is soon grown over, and the roots of the Grass receive the full benefit thereof; and at this season there is no danger of any part being washed off by the rains of winter. In cases where it is inconvenient to apply manure to Grass at this season, the next best time was considered to be in the spring, just when the Grass is expected to begin growing; and, in this climate, probably the beginning or middle of March might be suitable.

Miscellaneous.

Lucerne.—Select a dry piece of land, either rather light or good mixed soil, but not stony, strong, or clayey, certainly not the least inclined to be wet or springy, with either a sand or chalk subsoil—the latter is preferable; let it be made perfectly clean, especially from Couch-grass, and deeply ploughed; but if on a small scale I would have it dug by spade, or four-pronged carrot-fork (prongs 10 inches long and a little flattened), digging in plenty of good rotten farm-yard manure. When the ground is ready for the seed, open drills with a hoe 17 or 18 inches apart, and not more than 1½ or 2 inches deep; then put the seed in a glass wine-bottle with one or two quills stuck in with the cork (which is cut on the sides to admit the quills); this will deposit the seed more regularly than by hand into the drills, which are then raked over; about 24 lbs. of seed per acre is sufficient, which can be procured of any respectable seed-merchant, at 11*d.* or 1*s.* per lb. I consider May the best time for sowing, but if the ground is not too dry for the seed to vegetate, any time before the middle of August will do; but if the land is not perfectly clean, let the sowing be put off till the spring, and without a crop of Corn. It is fit to cut for a first crop of Hay generally from the 20th to the 28th of May, the year after sowing (this year it was a fortnight earlier), and for a second crop when it comes into blossom; it takes a longer time making into Hay than Grass, as it is better only turned, not shaken out, otherwise much leaf is lost. The crop must be well manured every year in January, February, or beginning of March, and the ground between the drills kept perfectly free from weeds by hoeing in dry weather, and picking the Grass out of the drills where the hoe would cut off many of the plants. The grand secret in growing Lucerne, I am persuaded, is in keeping it clean, and, when kept so, no green crop can bear any comparison in value; it is very far superior to Tares. I have now a third crop fit to cut, 26 inches high, on the same ground I cut for Hay only five weeks since. No lime must be used for manure. I am inclined to think guano mixed with farm-yard manure would answer well. If the quantity to be laid down be more than one acre, the plough and drill must be used, in which case it should be put in not more than two inches deep.—*Correspondent of Mark Lane Express.*

Burning Clay.—"Let sods be cut of a convenient size to handle—say a foot wide and 18 inches in length; with these form a parallelogram, or 'long square;' let the walls be a couple of feet thick, and trampled or beaten firmly together, and raised at least three feet high; the kiln should be so situated that the wind may blow against one of its sides; the kiln may be from four to six yards long by three yards wide, and an aperture, within one yard of each end, and others at a distance of about five feet from these, should be left in the side walls, when building, for the purpose of forming drain-like openings across the kiln; make one of these drain-like openings from end to end in the length of the kiln; these funnels

are to be built also with sods; some dry turf, such as is used for fuel, is to be put into these funnels, and over it and between the funnels well dried sods, or any other combustible materials are to be laid on to the depth of a couple of feet over these sods, partially dried, to the level of the walls of the kiln; these materials being set on fire, a powerful heat will be produced, quite capable of burning clay, without previously drying it; care, however, will be necessary, to avoid throwing it on in too great a quantity at once, until the fire is well up, when a large quantity may be thrown on. The sod walls are to be raised as the heap rises, and as soon as it is perceived by the strength of the smoke and the glow of heat that the mass is ignited in all its parts, the apertures may be closed up, and the kiln left to become charred; should appearances indicate a likelihood of being smothered, it will only be necessary to open one or more of the funnels to secure its acting. If the land on which the burned or charred clay is to be applied be deficient in calcareous matter, earth containing it, if burned, would improve it much. Excellent crops of Turnips are produced on indifferent land by the use of the clay ashes; and there can be scarcely a better preparation for Rape. There is no process in agriculture that demands the farmer's closer attention and personal superintendence, than burning clay; for if well done, there is no improvement so cheap, and at the same time so valuable; if on the other hand the burning is hurried, or the fires neglected, the consequence will be, either the clay will be burned into lumps like brick ends, that will not fall to pieces when exposed to the air, or the clay will not be charred, or burned at all; therefore the heat should always be slow and steady, never, if possible, burning the clay red, but black—although this is difficult to manage, depending much upon the wind, stopping up the apertures on the windward side, when the wind blows fresh, and opening the opposite aperture, and particularly attending to this. The whole time the heaps are burning will take from two to three months, the time depending much on the weather; from 60 to 100 yards may be burned in a heap; and if there be not sufficient sod, coarse turf, bushes, &c., on the spot to keep up a sufficient body of fire at the commencement, wood of any kind, or small coal must be used."—*Third Report of the Monmouth Farmers' Club.*

Naturalisation of the Alpaca in Scotland.—The Alpacas arrived the latter end of August. When the weather became cold, and the nights were getting long, a wooden shed was erected for them in the park. At first they hardly ever went into it; but when winter commenced, I made the keeper (whom they follow like a dog) put up a small rack in their shed, in which was placed some Rye-grass Hay. The weather was fine, and they ate very little of it; but by and by, as winter advanced, they relished it better. I then ordered them to get a few yellow Turnips, which at first they seemed to like, but, tiring of them, I desired a little corn to be given, which they partook of pretty freely; but one day the keeper told me they would not eat their corn, especially when the day was good. Having some excellent Beans, I ordered the man to try them with a few. No sooner did the Alpacas hear the Beans rattling in the dish than they showed an eager desire to have them, and during several months, preferred them to every other sort of grain; indeed, so much so, that upon some Oats being intermixed with the Beans, the latter were picked out and the former neglected. What is extremely satisfactory is the hardiness of these animals compared to our sheep, and their indefatigable perseverance in searching for food, when sheep would to a certainty starve. I may state that this winter, 1843-4, has proved a most severe one. The park in which the Alpaca and sheep were confined, was covered for nearly three weeks with snow; and during that time there was not a vestige of herbage to be seen, with the exception of some little green tufts under the trees. The sheep required to be regularly fed with Turnips and Hay. Not so the Alpacas; they were seen in the most stormy days under the trees for hours, constantly eating the Grass, and never minding either the cold or snow. They have never had a day's illness, have never attempted to leap a fence, and are far easier to keep within an inclosure than the common sheep.—*Mr. Stirling, in the Transactions of the Highland Society.*

Notices to Correspondents.

ANALYSIS OF ONION, &c.—*J. Jackson.*—We know of none which gives the mineral component parts, which is almost the only useful part of an analysis to the farmer or gardener.

BOOKS.—*R. W. L.*—"The Farmer—Knight's Guide to Trade;" "Essay on the Improvement of Small Farms," by W. Blake, Esq.; Martin Doyle's "Flower Garden." There neither is, nor can be, any general work on Gardening, of such a price as you mention. Apply to the booksellers: we do not give prices.

CABBAGES.—*Subscriber.*—Sow Early York and Imperial in seed-beds now, to transplant before winter and to be ripe in May. Sow the Drum-head Cabbage in March for consumption about August. The first are small early varieties; the last is a large Cabbage.

FEAT IN PLOUGHING.—*M. Saul.*—Thank you for your account received some weeks ago. It was not thought of sufficient *general* interest for insertion.

GAS-LIME.—*F. C.*—You had better mix your pond and ditch mud with gas lime, turning it frequently before applying to the land; this you can do before Wheat-sowing; get old gas-lime if you can.

GRASS.—*Peel.*—Your Grass is a Lolium, or Rye-Grass, the seed of which may be usefully saved.

GREEN MANURE.—*E. B.*—The practice of ploughing green crops in as manure can rarely be characterised as economical. If your land require manuring for Wheat—if it be a stiff soil, you should have sown Vetches and eaten them off by sheep on the land. Sow one and a half bushel of Buck Wheat, broadcast, on a light soil, in the middle of May. Sow Lupines as you would Peas—plough them down when in flower. Mustard should be sown in May, 4 or 5 lbs. per acre, in rows—say 12 inches apart—or broadcast, and ploughed in just before flowering.

GUANO, &c.—*Peel.*—This manure, especially the African, is frequently delivered very damp; whether naturally or artificially so, is another question. We have known it to contain 20 per cent. of water. The value of marl depends altogether upon its composition, and frequently upon some of its smallest ingredients (*see* Sprengel on the subject in late Nos. of this Paper). The proper way to apply it is before winter, as fine as possible; when spring comes it is in a state to be spread evenly and buried. It may form a useful ingredient in a compost, especially if ultimately used on a light soil. Thanks for your paper on Rooks.—*J. C.* asks if any of our correspondents will favour him with their experience of African, Peruvian, and Bolivian guanos, also of rapedust and soaper's ashes, as manures? With *reference to* the last, see Sprengel in this and next Papers.

INSECTS.—*A. B.*—I am glad you sent the insects, for they are one of the best friends you have, being the larvæ of the Lady-birds, which feed entirely upon the plant-lice that are infesting your Swedes. *Vide* the "Royal Agricultural Journal," Vol. iii. p. 56, and pl. c. f. 13-17.—*J. W. L.*—Your Turnip-leaves are covered with Aphides, and the larger insects accused of cutting off the heads of the young Turnips are the larvæ of the Lady-birds, as you imagined, which live entirely on plant-lice, and must not be destroyed. We will make this the subject of a paper as soon as possible. *R.*—*A Leicestershire Farmer.*—The flies you sent are the Aphis rapæ, whose history you will find in the "Royal Agricultural Journal," Vol. iii. p. 53.—*A Subscriber, Waterford.*—Your last supply enables us to state that your Turnips are suffering from the Aphides, a vast portion of which are punctured by parasitic flies. You will be interested with the history of these insects given in the "Royal Agricultural Journal," vol. iii. p. 49. *R.*

LINSEED AS FOOD.—*J. C.*—We had hoped to have been able, before this, to have published on this subject. We shall do so shortly. Wheat straw, *ad. lib.*, cut into chaff and steamed with 2 or 3 lbs. of Barley meal a day, would probably answer your purpose, though in this we do not speak from experience.

LUCERNE.—*Subscriber.*—Sow 12 lbs. of seed in rows about 1 foot apart, on well and deeply-tilled ground, before the middle of April. You will be able to cut it once in the autumn of that year, and four or five times next year. (See *Miscellaneous*, No 32 *Agricultural Gazette*.

MANURE.—*G.*—If the analysis you give is correct, lime will benefit your soil: you may safely put 150 to 200 bushels per acre on it. As to the probability of muriate of soda benefiting you, this will be better indicated by your distance from the seashore, than by your analysis, which does not enter sufficiently into detail. If you are inland, apply common salt, 1 cwt. per acre.

PEAS.—*Subscriber.*—The Nimble Pea and the Early Warwick, are early Peas, much in favour with market-gardeners.

REARING CALVES, &c.—*W. C.*—The following is the way in which the best Gloucestershire dairy-farmers manage:—The calf is removed from the cow at six or eight days old, provided the dam be a cow and not a heifer; if a heifer, the calf is allowed to remain about a fortnight, because a heifer is more difficult to be milked, and the calf assists the milker. No difference is made whether the calf be heifer, steer, or bull; they are all reared exactly in the same way. At about a week old calves are allowed each two quarts of best milk twice per day: this is every thing given till about two months old, except Hay, which they generally eat well at a very early age—say three weeks. After two months old they consume a good quantity of Hay, and then we reduce the two quarts of milk to one, and add two quarts of water, which makes a mixture of three quarts, as of course they require more to drink, as they consume more Hay. At about ten weeks old they are turned to Grass, and all the milk is discontinued by degrees. The longer a calf remains with its mother the more will it feel the loss when taken away. The age of sixteen months is the correct time to put the heifer to the bull, so that she may calve at two years old, or thereabouts. This, undoubtedly is the best time for a dairy; but, should the chief object be symmetry and size, without much regard as to profit, by allowing them to remain until three years old before they calve, you gain your object. No difference is made in selecting calves, whether they are from heifers or cows; a heifer's first calf is equally good with the second. The objection to weaning the first calf generally arises from the heifer calving later in the season than cows, which is generally the case. It is not at all desirable that the heifer should suckle her first calf, except for the limited period before mentioned. The heifer should be made quiet for milking as soon as possible, which object is defeated by allowing the calf to suck.—*E. H.*

REARING YOUNG CATTLE.—*A Terfi-side Subscriber.*—See answer to similar question above. Also see Paper on this subject in No. 1. *Agricultural Gazette*, by Mr. Wilson, extracted from "Quarterly Journal of Agriculture."

SKINLESS OAT.—*Paddy.*—We do not know if the skinless Oat, introduced some years ago from China, is the same as that found in County Galway and other parts of Ireland.

VETCHES AND ITALIAN RYE-GRASS.—*A. Huxtable.*—We doubt the propriety of sowing the two together. In the only case in which we have done so on a large scale, the Rye-Grass had perished before the Vetches were cut.

WEED.—*R. T. C. J.*—Your weed is, apparently, some species of Lolium or Rye-Grass. The proper remedy is to take two fallow crops in succession—say Potato and Swedes, and clean the land well in both cases before taking a grain crop.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, Aug. 5.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	8	to	4s	0		
Best Short Horns	3	6		3	10		
Second quality Beasts	3	0		3	6		
Calves	3	8		4	4		
Pigs	3	4		4	0		
Best Downs & Half-breds	3s	8	to	4s	0		
Best Long-wools	3	6		3	10		
Ewes and second quality	3	2		3	6		
Lambs	4	0		4	8		

Beasts, 5302; Sheep and Lambs, 28,970; Calves, 197; Pigs, 310.

Our supply of Beef to-day is very large, but a great many of them are of very inferior quality; some of the best Scots, &c, are still making 4s, but this price for anything is more difficult to be obtained than on last Monday; and 3s 10d is quite an extreme price for the best Short-horns. Second quality Beasts are a very heavy sale, a great many making very little over 3s per 8 lbs; several of this description remain unsold. The supply of Mutton, although considerably shorter than on last Monday, is still adequate to the demand, which rules heavy and the advance in prices which was obtained on Friday is not supported to-day. The Lamb-trade is declining very fast—a great many of the larger sort only make Mutton price; in some few instances 4s 8d is obtained for very nice quality, but this is a rare price. Veal is rather lower than on Friday—a very nice Calf is, however, still worth 4s 4d. Pork is about the same.

FRIDAY, Aug. 9.

The supply of fresh Beasts to-day is not very great, but with what were left over from Monday, there are too many for the demand. Trade is very heavy, at barely Monday's prices—indeed, we cannot quote the best Scots, &c., at more than 3s 10d, and Short-horns 3s 8d per 8 lbs. Mutton-trade is very heavy at hardly so good price as on Monday, but scarcely a quotable difference. Lamb is going out, and for the most part is making very little more than Mutton; prices range from 4s to 4s 6d. Veal is a little lower, it being difficult to make 4s 4d of the very best; many very good Calves are sold at very little over 4s per 8 lbs. Pork, 3s 6d to 4s.

Beasts, 782; Sheep and Lambs, 11,940; Calves, 200; Pigs, 290.
41, West Smithfield.

HAY.—Per Load of 36 Trusses.

SMITHFIELD, Aug. 8.

Prime Upland Hay	80s to 105s	Clover	100s to 115s	Straw	28s to 32s

				Joshua Barnes, Hay Salesman.	

WHITECHAPEL, Aug. 9.

Fine Old Hay	80s to 90s	Old Clover	120s 130s	Straw	24s to 30
New Hay "	75 82	New Clover	98 110		

COVENT GARDEN, Aug. 12.—The late fine weather has caused a good supply of orchard fruit to be brought into the market. The quantity of Vegetables, generally speaking, is also amply sufficient to meet the demand. Pine-apples are very plentiful; among them we noticed some fine specimens of Providences and Queens; they are not altered in price since our last report. Large quantities of the foreign Pines formerly alluded to are in the market, and, although still much inferior to English-grown varieties, they are somewhat improved in quality; they bring from 1s. to 5s. each. Black Hambugh and Muscat Grapes, of good quality, are abundant. Foreign Melons continue to be pretty well supplied, but those of home growth are becoming less numerous. Peaches and Nectarines are sufficient for the demand; a few from the open walls have been supplied during the week. Apricots, Green Gages, and several kinds of Plum are now offered in considerable quantities. Cherries are becoming scarce, and Gooseberries and Currants are also less plentiful. Apples chiefly consist of the Junegating, Red Astrachan, and Hawthorndean. Among Pears Jargonelles are most prevalent. Filberts have just made their appearance. A few Strawberries are still to be met with. Of Vegetables the supply of Peas is becoming somewhat limited, and they are considerably advanced in price. Artichokes are good. A few Tomatoes have been offered at about 1s. 6d. per punnet. The best Mushrooms are selling at about 2s. per pottle. Cabbages are good and plentiful. Cauliflowers, although still sufficient for the demand, are getting scarcer. Carrots are good and plentiful; but Turnips are very scarce. Salading and Herbs of every kind are abundant. Cut Flowers chiefly consist of Bignonia venusta, Ceanothus azureus, Alstræmeria pelegrina, Fuchsias, Heaths, Pelargoniums, Carnations, Picotees, Verbenas, Gardenias, and Roses.

FRUITS.

Pine Apple, per lb., 4s to 6s		Plums, per half-sieve, 1s 6d to 2s	
Hothouse Grapes, per lb., 2s to 6s		Strawberries, per gallon, 1s 6d to 2s

Southdown Fleeces	1 0		1 1		

JAMES PEARSE, Wool Broker.

HOPS, FRIDAY, Aug. 9.

The accounts from the plantations have continued to come worse daily during the week; the duty has fallen to 130,000*l*., and prices have advanced 4s to 10s per cwt.

PAVERSHAM & SMITH, Hop-Factors.

MARK-LANE, MONDAY, Aug. 5.

WITH a short supply of Wheat from Essex, Kent, and Suffolk, the market was rather better than on Monday last, and fully equal to Friday; but there is no inclination to pay any advance. In Foreign there was a fair retail sale for consumption, and its value may be considered the same as last week.—Flour has declined 3s. per sack.—Barley, both English and Foreign, is 1s. lower, and Peas have receded 1s. to 2s. per qr.—In Beans there is no alteration.—Oats are a very slow sale at late rates.

BRITISH, PER IMPERIAL QUARTER.	s.	s.		s.	s.
Wheat, Essex, Kent, and Suffolk . . White	40	48	Red .	42	47
—— Norfolk, Lincolnshire, and Yorkshire . . —	—	—	White	—	—

—— Pigeon, Hollgoland . 32 to 35	Winds.	—	—	Longpod	—	—
Peas, White . . . . 32 to 36	Maple	32	33	Grey	31	29

FRIDAY, Aug. 9.

The weather has continued unsettled from Monday last, but we have had scarcely any rain since Wednesday; on that day there was a fair demand for Foreign Wheat, which in some instances brought an advance of fully 1s. per qr., but to-day there is less doing; Factors, nevertheless, are unwilling to accept the rates of our last quotations. We have had but little English fresh up during the week, and observe no alteration in its value.—Barley remains as last quoted, but grinding qualities are rather more inquired after.—Beans and Peas are unaltered. Oats are more in demand, at 6d. advance.

TO FLORISTS AND AMATEURS OF FLOWERS.

BRAIN'S CONCENTRATED LIQUID GUANO, for the Garden, Shrubbery, Hothouse, and Conservatory.

This preparation is peculiarly adapted for the development of flowers, furnishing them with the materials (in a soluble form) out of which they weave their delicate tissues and elaborate their beauteous colouring. It has no unpleasant smell, is easily applied, and thus recommends itself, either for the Garden or Drawing-room.—Price 1s. 6d. per quart Bottle, and may be had of most respectable Druggists and Seedsmen, with full directions for use inclosed.—Works, Thomas-st., Stamford-st., Blackfriars-road.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought to the market.

Price-current, London, Aug. 8, 1844:—

WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street.

LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of, LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also, those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for hire, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset-street, Fleet-street, London

---

GYPSUM, &c.—Pure Gypsum (Sulphate of Lime) for Compost Heaps, Urine Tanks, Stables, &c.: also Sulphuric Acid, Guano (foreign and Potter's), Rape Cake and Rape Dust, and all other Manures, may be had of the Undersigned.

Synopsis of Prices, and mode of use, on application.

MARK FOTHERGILL, 40, Upper Thames-street.

TURNIPS, &c.

DR. HALLETT'S DRY SOLUBLE FERTILISERS are composed of all the useful ingredients of the best Foreign Guano, which manure is already nearly exhausted, and no two parcels of which were ever alike. They contain also other ingredients equally useful, and are always to be produced of uniform strength; they are improvers of all soils, but most so of poor ones, and cannot possibly prove injurious to soil or crop, as they contain no heating or caustic materials, being simply and purely Fertilisers. Five cwt. of either of them is equal to nearly 30 tons of horse-manure as a Fertiliser. They are used, the one for all the varieties of Corn, Peas, Beans, Chicory, &c., and the other for Turnips, Mangold Wurzel, Natural and Artificial Grasses, and all Gardening purposes. This is the best protector yet discovered against the Fly in Turnips, for it gives a first growth three weeks beyond that of any other known Manure. Price of each Fertiliser, 10l. per ton, or 12s. per cwt.

Sold by Mr. FOTHERGILL, 40, Upper Thames-street; and Mr. G. HALLETT, at the Factory, Broadwall, Blackfriars, London. The Fertilisers are manufactured under the immediate inspection of J. J. HALLETT, M.D., &c.

Agents for London, Messrs. WINSTANLEY, Chemists, 7, Poultry; Suffolk, Mr. W. REVANS, Yoxford; Norfolk, Messrs. BUÉLAND and WATTS, Norwich; Jersey, Mr. C. Kruger. Respectable country agents wanted.

TO COLONISTS, EMIGRANTS, &c. — Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, FENCHURCH STREET, CITY, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hay-making Machines	Flour-Mills—Bean-Mills
Dressing Machines	Patent Essex Ploughs, 30 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs [Colonies
Oil-Cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch Street, London.

DRAINING OF LAND.

THE A LEVEL, designed for the Use of Workmen, in preserving a uniform fall in Drains and Water-courses. In consequence of the approval expressed and the demand made for these Levels at the recent Southampton Show, Mr. BAILEY DENTON has arranged with an eminent London Mathematical Instrument Maker to make them in any number required. Price 30s.

This Level is as accurate as a spirit-level, and so simple, that the workman unable to read can use it with facility. When closed it forms a 5 feet staff.

Orders addressed to Mr. DENTON, Land Agent, 9, Gray's Inn-square, will insure a perfect instrument.

70, STRAND, LONDON.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

ASPHALTE.—BROWN OIL VARNISH, BLACK VARNISH PAINT.—Asphalte in a pure state, without grit, 5s. per cwt., in casks 2 cwt. each, for forming or improving garden walks, terraces, court yards, stables, ground-floors, roofs, or for applying to damp walls. Brown Oil Varnish for varnishing gates, outhouses, fences, &c., 8d. per gallon—it dries very quick. Black Varnish Paint for outhouses, fences, &c., 8d. per gallon.—R. RICHARDSON, Net and Tent maker, 21, Tonbridge-place, corner of Judd-street, New Road, London.—Pitch 5l. per cwt. Stockholm Tar, &c.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved as efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade. Thos. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

TANNER'S VITREOUS FLUID and CLOTH, a Substitute for Glass for Horticultural Purposes.—The Vitreous Cloth proves its superiority over Glass, by producing the light most suitable to vegetation, superseding the necessity of any shading, preserving a healthy moisture on the plant, retaining its bloom to a more lengthened period, less expensive, and not requiring so much attention. The above (retaining heat) is preferable to Glass for Hothouses, &c., the temperature of which is maintained with less fuel. It is equally applicable as a covering for Fruit-trees, preserving them from frost, blight, and excessive heat. The Vitreous Cloth, made by machinery, is much superior to any prepared in a different manner. By the use of the Vitreous fluid, the Cloth (after lengthened service) may be renewed.

The Fluid sold in bottles 2s. 6d. and 4s. 6d. The Cloth 2s. 6d. and 3s. per yard. Manufactured by N. W. TANNER, Chemist, Exeter. Agents for Exeter and vicinity, Messrs. LUCOMBE, PINCE, & Co, Exeter Nursery. Liverpool. Mr. CUNNINGHAM, Nurseryman, Paradise-street.

N.B. The Vitreous Cloth (if fixed in the manner recommended by the Proprietor) will stand *a much greater pressure* of air than glass.

To Mr. N. W. Tanner—Sir, we have used your prepared Cloth, and have pleasure in informing you that whilst the light admitted through it is very suitable to vegetation, there has been no necessity to have recourse to any extra shading during the very clear, bright weather which we have so long experienced; this we consider an important point. Yours, &c.

(Signed) LUCOMBE, PINCE, & Co., Exeter Nursery.

June 21, 1844. *** Respectable Agents required.

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of searching thoroughly into the divisions of the teeth, and cleaning them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose—1s. An improved Clothes Brush, that cleans in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and successful manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the luxury of a genuine Smyrna Sponge. Only at METCALFE'S Sole Establishment, 130B, Oxford-street, one door from Holles-street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

EXTRACT FROM OLD MOORE'S ALMANAC for 1844.—"AUGUST.—CARE OF HEALTH.—This is generally the hottest month in the year; languor and inability for active mental and bodily exertion is experienced by all, but more especially by ladies and those of delicate constitution. Recourse should be had to that excellent medicine, Parr's Life Pills, which will quite re-invigorate the whole system, and render the heat of this month, which is otherwise so oppressive, as delightful as any month in the year."

PARR'S LIFE PILLS are sold by all respectable Medicine Venders.

See the words "PARR'S LIFE PILLS," in White Letters on a Red Ground on the Government Stamp.

EXTIRPATION of all kinds of VERMIN.—Office, 69, King William-street, city, London.—Mr. J. A. MEYER, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Gaily Quays and warehouses in Lower Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5s., 10s., 20s., 50s., and 100s. each, with full directions, which must be used in proportion to the extent of premises infested, to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling-houses cleansed from 1l. to 5l. per annum; mansions and estates from 10l. and upwards; ships, docks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

GARDEN NETS, FISHING NETS, RABBIT NETS, SHEEP NETS, &c.—New Garden Net, 1 inch mesh, 1½d. per yard; ¾ inch mesh, 2½d. per yard. Old Fishing Nets, mended up, 3d. per yard. Fine-mesh Net, to effectually exclude wasps and flies, and allow sufficient sun and air to the Fruit, 7½d. per yard. Much-approved Fishing Nets, viz.—Fine Nets, of silk and thread; Drag Nets; Casting Nets; Hoop Nets, and all kinds of Nets for Sea, River, and Pool Fishing. Rabbit Nets, on cords from 50 to 100 yards long each. Net for fencing out Rabbits, 2d. per yard. Net to inclose Fowls and Pheasants, 2d. per yard. Sheep Nets, made of strong cord, 4½d. per yard; nearly 4 feet high. Nets of all kinds made to order.—ROBERT RICHARDSON, Net and Tent Maker, No. 21, Tonbridge Place, New Road, corner of Judd-street, London.

TARPAULIN CAPES, COATS, and WAGGON-COVERS.—Above 2000 London Policemen's Capes, for Gardeners, Labourers, and Farm-servants, lined, 2s. and 2s. 6d. each; large Tarpaulin Capes, for Gamekeepers and Watchmen, 7s. each; Do., rather smaller, 6s.; Tarpaulin Coats, 4s. 6d. each; Waggon and Cart-covers of Tarpaulin, 2s. 3d. per square yard; Hay Cart-covers; Patent India-rubber Tarpaulin Waggon and Cart-covers, 3s. per square yard; several hundred Tarpaulin Frame-covers, second-hand, but perfect, quite the size of the largest mats, 3s. 6d. each, will last several years, and keep in twice the heat of mats; new Tarpaulin do., 5s. each; Tarpaulin Pit and Frame-covers, Coach and Dog-cart Aprons, Horses' Loin Cloths; Woollen Horse Clothing and Blankets, largest and heaviest made, 12s.; Do., same size, lighter, 10s., made to order any pattern.—ROBERT RICHARDSON, Net and Tent Maker, 21, Tonbridge-place, corner of Judd street, New Road, London. Tents, Marquees, and Tarpaulins on hire. Roofing Canvas, 3½d. per foot.

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c. Manufactured by DOULTON and WATTS, LAMBETH POTTERY, High-street, Lambeth, London.

D. and W., from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone or Cement is well known. It is subjected to a high degree of fire, which renders it imperishable, and gives it a sharpness and surface which no changes of temperature can impair.

D. and W. are enabled to offer the Terra Cotta at a considerable reduction in price; and Drawings and Designs will be forwarded Gratis, on application.—Architectural work executed

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June* 6, 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 8, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

FIDDLE and PRINCE ALBERT'S PATTERN PLATE.—A. B. SAVORY and SONS, Manufacturing Silversmiths, No. 14, Cornhill, opposite the Bank of England.—The best wrought SILVER SPOONS and FORKS, fiddle-pattern, 7s. 2d. per ounce; the Prince Albert's pattern, 7s. 6d. per ounce. The articles may be had, lighter or heavier, at the same price per ounce:—

INTERESTING TO LADIES. — To MESSRS. ROWLAND & SON, 20, Hatton Garden, London.—"Percy Place, Landport, Portsmouth, April 4, 1844. GENTLEMEN,—I think it but an act of justice to inform you of the benefit I have derived from the use of your admirable Macassar Oil. About six months ago I found my hair getting daily more weak and thin, and much discoloured from a practice I had adopted of wetting it continually; fearing that I should lose it entirely, and hearing of the efficacy of your Macassar Oil, I have for some time past constantly used it, and the result is, that my hair is now perfectly restored and much improved in appearance and colour, having become thick, dark and glossy; it also curls freely without the use of paper, which it never did before. To all my friends I have warmly recommended your Macassar Oil as an excellent restorative and preservative for the Hair. As I have an objection to see my name in print, I beg you will not publish it; but you are at liberty to show this letter, or make any other use you please of it, and refer applicants to me if necessary, in proof of the efficacy of your Macassar Oil. Your Obt. Servant **"

ROWLAND'S MACASSAR OIL preserves and reproduces the Hair; prevents it from falling off or turning Gray; changes Gray Hair to its original colour; frees it from Scurf and Dandriff, and makes it beautifully soft and curly.

*** Ask for "ROWLAND'S MACASSAR OIL." All others are Fraudulent Counterfeits.

REALLY WATERPROOF.

BERDOE'S SUPERIOR WATERPROOF FROCKS, SHOOTING-JACKETS, GARMENTS for the SEA-SIDE, &c.—An extensive variety of the above, in NEW and greatly improved materials always ready, guaranteed to exclude any rain whatever, and confidently recommended to those who regard a respectable appearance, or wish to avoid the disappointment and vexation consequent upon purchasing articles made by slopsellers, and sold by parties not Tailors.

FIRST-RATE CLOTHING of every description, upon the lowest terms possible, consistent with TRUE economy, and ultimate satisfaction.—W. BERDOE, Tailor, Waterproofer, &c., 69, Cornhill (north side).

PUBLISHED FOR
TAYLOR AND WALTON,
BOOKSELLERS AND PUBLISHERS TO UNIVERSITY COLLEGE
UPPER GOWER-STREET.

DARLEY'S
SCIENTIFIC LIBRARY
FOR THE USE OF
SCHOOLS, PRIVATE STUDENTS, ARTISTS, AND MECHANICS.

It is the purpose of this Work to furnish a Series of Elementary Treatises on Mathematical Science, adapted to the wants of the public at large To youth of either sex at public and private schools to persons whose education has been neglected, or whose attention has not been directed in early life to such studies, and to Artists and Mechanics these little works will be particularly suited The principles of the various Sciences are rendered as familiar and brought as near to our commonest ideas as possible the demonstrations of propositions are made plain for the mind and brief for the memory and the Elements of each Science are reduced not only to their simplest but to their shortest form

I
A NEW EDITION (being the fifth) *is now ready*,
A SYSTEM
OF
POPULAR GEOMETRY;
Containing in a few Lessons so much of the Elements of Euclid as is necessary and sufficient for a right understanding of every Art and Science in its leading truths and great principles
BY GEORGE DARLEY, A.B.
Price 4s 6d, cloth

II
NEW EDITION (just published),
COMPANION
TO THE
POPULAR GEOMETRY;
In which the Elements of Abstract Science are familiarised, illustrated, and rendered practically useful to the various purposes of life, with numerous Cuts
BY GEORGE DARLEY, A.B
Price 4s. 6d, cloth.

III
THIRD EDITION,
A SYSTEM
OF
POPULAR ALGEBRA;
WITH
A Section on PROPORTIONS and PROGRESSIONS.
BY GEORGE DARLEY, A.B.
Price 4s 6d
"For students who only seek this limited knowledge of these sciences, there are, perhaps, no treatises which can be read with more advantage than Darley's Popular Geometry and Algebra."
—*Library of Useful Knowledge, article "Mechanics."*

IV
SECOND EDITION,
A SYSTEM
OF
POPULAR TRIGONOMETRY,
Both Plane and Spherical.
With POPULAR TREATISES on LOGARITHMS, and the Application of Algebra to Geometry.
BY GEORGE DARLEY, A.B.
Price 3s 6d, cloth.

V.
FAMILIAR ASTRONOMY.
BY GEORGE DARLEY, A.B
WITH ENGRAVINGS —12mo, 6s, cloth lettered.
"There is a vast deal of astronomical information conveyed in a most winning and unassuming manner in this delightful little volume, which, if less for the novelty of its plan than the extent of its intelligence, reflects infinite credit on the taste and talents of its projector and editor, Mr. Darley."—*Sun.*

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—ANNUAL COUNTRY MEETING of 1845, to be held at SHREWSBURY, in the North Wales District, comprising the Counties of Anglesey, Carnarvon, Merioneth, Montgomery, Denbigh, Flint, Chester, Salop, and Stafford. The Prizes are open to general competition. Forms of Certificate to be procured on application to the Secretary, 12, Hanover-square, London. All Certificates for Implements must be returned, filled up, to the Secretary, on or before the 1st of May, and all other Certificates by the 1st of June; the Council having decided that in no case whatever shall any Certificate be received after those dates respectively.

PRIZES FOR IMPROVED BREEDS OF CATTLE, &c.—1845.

Short-horns.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 50*l.*; to the owner of the second best do. do., 15*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 25*l.*—3. To the owner of the best Cow in milk or in calf, 25*l.*—(In case of the Cow being in calf, and not in milk, the Prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in calf Heifer, not exceeding three years old, 15*l.*—5. To the owner of the best Yearling Heifer, 10*l.*—6. To the owner of the best Bull-calf, not exceeding one year old, 10*l.*

Herefords.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 50*l.*; to the owner of the second best do. do., 15*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 25*l.*—3. To the owner of the best Cow in milk or in calf, 15*l.* (In the case of the Cow being in calf, and not in milk, the Prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in-calf Heifer, not exceeding three years old, 15*l.*—5. To the owner of the best Yearling Heifer, 10*l.*—6. To the owner of the best Bull-calf, not exceeding one year old, 10*l.*

Devons.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 50*l.*; to the owner of the second best do. do., 15*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 25*l.*—3. To the owner of the best Cow in milk or in calf, 15*l.* (In the case of the Cow being in calf, and not in milk, the Prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in-calf Heifer, not exceeding three years old, 15*l.*—5. To the owner of the best Yearling Heifer, 10*l.*—6. To the owner of the best Bull-calf, not exceeding one year old, 10*l.*

Cattle of any Breed (not qualified to compete in the foregoing classes).—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 20*l.*; to the owner of the second best ditto, 10*l.*—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 15*l.*—3. To the owner of the best Cow in milk or in calf, 15*l.* (In the case of the cow being in calf, and not in milk, the prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in-calf Heifer, not exceeding three years old, 15*l.*—5. To the owner of the best Yearling Heifer, 10*l.*

HORSES.

CLASS 1. To the owner of the best Stallion for Agricultural Purposes, of any age, 30*l.*; to the owner of the second-best do. do., 15*l.*—2. To the owner of the best three years old do., 15*l.*—3. To the owner of the best two years old do., 10*l.*—4. To the owner of the best Mare and Foal for Agricultural Purposes, 20*l.*; to the owner of the second-best do., 10*l.*—5. To the owner of the best two years old Filly, 10*l.*—6. To the owner of the best Thorough-bred Stallion, which shall have served mares at a price not exceeding 3 guineas (and with a groom's fee of not more than 5*s.*) in the season of 1845, 20*l.*

SHEEP.

PRIZES FOR IMPROVED BREEDS OF SHEEP.—1845.

Leicesters.—CLASS 1. To the owner of the best Shearling Ram, 30*l.*; to the owner of the second-best do., 15*l.*—2. To the owner of the best Ram of any other age, 30*l.*; to the owner of the second-best do., 15*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second best do., 5*l.*

South-down Sheep.—CLASS 1. To the owner of the best Shearling Ram, 20*l.*; to the owner of the second-best do., 15*l.*—2. To the owner of the best Ram of any other age, 30*l.*, to the owner of the second-best do., 15*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do., 5*l.*

Long, Woolled Sheep. (Not qualified to compete as Leicesters.)—CLASS 1. To the owner of the best Shearling Ram, 30*l.*; to the owner of the second-best do., 15*l.*—2. To the owner of the best Ram of any other age, 30*l.*; to the owner of the second best do., 15*l.*—3. To the owner of the best pen of five Shearling Rams, 10*l.*; to the owner of the second-best do., 5*l.*

Sheep best adapted to a Mountain District.—CLASS 1. To the owner of the best Ram of any age, 15*l.*; to the owner of the second-best do., 10*l.*; to the owner of the third-best do., 5*l.*—2. To the owner of the best pen of Ewes of any age, 10*l.*; to the owner of the second-best do., 5*l.*

PIGS.

CLASS 1. To the owner of the best Boar of a large breed, 10*l.*; to the owner of the second-best do. do., 5*l.*—2. To the owner of the best Boar of a small breed, 10*l.*; to the owner of the second-best do. do., 5*l.*—3. To the owner of the best breeding Sow, of a large breed, 10*l.*—4. To the owner of the best breeding Sow, of a small breed, 10*l.*—5. To the owner of the best pen of three breeding Sow pigs, of the same litter, above four and under ten months old, 10*l.*

AGRICULTURAL IMPLEMENTS.

A sum not exceeding 300*l.*

Cheese.—To the exhibitor of the best cwt. of Cheese (of any kind) made within the district, 10*l.* To the exhibitor of the second-best do., 5*l.*

Extra Stock, Roots, and Seeds.—For Extra Stock, of any kind, not shown for any of the above Prizes, and for Roots, Seeds, &c., Prizes may be awarded and apportioned, by the Committee and Judges, to an amount not exceeding in the whole 50*l.*

Any New Implement.—For the invention of any new Agricultural Implement, such sum as the Council may think proper to award.

Seed Wheat, Barley, and Oats.—I. Fifteen Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of white Wheat, of the harvest of 1844, and grown by himself.

II. Fifteen Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of red Wheat, of the harvest of 1844, and grown by himself.

III. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of spring Wheat, of the harvest of 1844, and grown by himself.

IV. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of Barley for malting, of the harvest of 1844, and grown by himself.

V. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of Oats, of the harvest of 1844, and grown by himself.

Competitors are requested to send with their Wheat, Barley, or Oats, specimens, fairly taken, of the same in the ear, with the whole of the Straw, in a sheaf not less than one foot in diameter, and with the roots attached.

The 14 bushels of the Wheat, Barley, or Oats, will be sealed up instantly by the Director or Stewards, and one of the remaining bushels Mr. Mechi's New variety will be exhibited as a sample to the public; Messrs. Page being kept for competition with the produce of the siderunc. Up, Bee. At the General Meeting in December, 1840, the from 8 till 8. Ohe awarded.

The two best samples of each of these classes of Wheat, Barley, or Oats, without at that time distinguishing, in any of the cases, between the comparative merits of either sample, will be selected by the Judges appointed for the Meeting at Shrewsbury; and will be sown, under the direction of the Council (the winter Wheats in the autumn of 1845, and the spring Wheat not earlier than the 1st of March, 1846), by four farmers, who will make their report, upon which the Prizes will be awarded, provided there be sufficient merit in any of the samples. 50*l.* will be given at the Meeting at Shrewsbury to each exhibitor whose Wheat has been selected for trial, and 6*l.* for the Barley or Oats.

*** No variety which has been selected for trial at any previous Show shall be qualified to compete in the same section.

ESSAYS AND REPORTS ON VARIOUS SUBJECTS.

Prizes for 1845.—PRIZE ESSAYS.

1. *Farming of Nottinghamshire.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Nottingham. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Nottinghamshire since the Report of Mr. Robert Lowe in the year 1798; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

2. *Farming of Cornwall.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Cornwall. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Cornwall since the Report of Mr. G. B. Worgan, in the year 1811; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

3. *Farming of Kent.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Kent. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Kent since the Report of Mr. John Boys, in 1805; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

4. *Heath Land.*—Twenty sovereigns, or a piece of plate of that value, will be given for an account of the best method of reclaiming heath-land. Competitors will be required to describe methods which have been successfully adopted in the reclaiming of heath-land, reference being had especially to the following points:—1. The mode of breaking up, whether by paring and burning, or by simple ploughing. 2. The application of lime. 3. The course of cropping. 4. The conversion of heath-land into pasture, where either the steepness of the land, or its elevation above the sea, does not allow the culture of corn.

5. *One Horse Carts.*—Ten Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on the advantages of One-horse Carts. Competitors will be required to point out the saving in horse-labour, and other advantages which undoubtedly arise from substituting 1-horse carts for waggons.

6. *Catch-Meadows.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on Catch-Meadows. Competitors will be required to describe the best and cheapest method of forming water-meadows on the sides of natural slopes, as practised in Somersetshire and Devonshire; the mode of managing them, and of applying their produce; the increase of value thereby given to unproductive hill-sides; and to state how far this mode of improvement might be applied to the mountainous districts of Wales and the North of England.

7. *Fences.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on Fences. Competitors will be required to describe the best and neatest methods of maintaining hedges, whether for arable or for grazing ground; and to point out how far the present fences in various parts of England are injurious to the farmer, whether by their size, their excess in number, or the over-abundance of timber which they contain.

8. *Fattening Cattle.*—Ten Sovereigns, or a Piece of Plate of that value, will be given for an account of the best method of fattening cattle; as to the places in which they are kept, large or small yards or stalls; as well as the food, roots, hay, &c. on which they are fed during the time of fatting.

9. *Tile yards.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the cheapest and best method of establishing a Tile-yard. Competitors will be required to attend to the following points:—1. Mode of working the clay, according to its quality. 2. Machine for making the tiles. 3. Sheds for drying the tiles. 4. Construction of the kiln. 5. Cost of forming the establishment. 6. Cost of the tiles when ready for sale.

10. *Curing Butter.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best description of the Dutch method of salting butter; pointing out the causes of its superiority to other salted butters.

11. *Experiment in Agriculture.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for an account of the best Experiment in Agriculture.

These Essays must be sent to the Secretary, at 12, Hanover-square, London, on or before March 1st, 1845.

Rules of Competition for Prize Essays.—1. All information contained in Prize Essays shall be founded on experience or observation, and not on simple reference to books, or other sources. 2. Drawings, specimens, or models drawn or constructed to a stated scale, shall accompany writings requiring them. 3. All competitors shall inclose their names and addresses in a cover, on which only their motto, and the subject of their Essay, and the number of that subject in the Prize list of the Society, shall be written. 4. The President or Chairman of the Council for the time being, shall open the cover on which the motto designating the Essay to which the Prize has been awarded is written, and shall declare the name of the author. 5. The Chairman of the Journal Committee shall alone be empowered to open the motto paper of such Essays, not obtaining the Prize, as he may think likely to be useful for the Society's objects, with a view of consulting the writer confidentially as to the best means to place such paper at the disposal of the Journal Committee. 6. The copyright of all Essays gaining prizes, shall belong to the Society, who shall accordingly have the right to publish the whole or any part of such Essays; and the other Essays will be returned on the application of the writer; but the Society do not make themselves responsible for the Essays. 7. The Society are not bound to award a prize unless they consider one of the Essays deserving of it. 8. In all reports of experiments the expenses shall be accurately detailed. 9. The imperial weights and measures only are those by which calculations are to be made. 10. No prize shall be given for any Essay which has been already in print. 11. Prizes may be taken in money or plate, at the option of the successful candidate. 12. All Essays must be addressed to the Secretary, at the house of the Society.

(By Order of the Council) JAMES HUDSON, Secretary.

REFINED PLEASURE to LOVERS of BOTANY.—The Nobility and Gentry are respectfully informed that the splendid WARDIAN PLANT CASES, which excited so much attention and obtained a Medal at the late Chiswick Fete, are now on view at No. 39, Argyll-street, Regent-street.

The suggestions of PROFESSOR LINDLEY have been earnestly carried out by the manufacturer, Mr. Ports, so as to elicit the entire approval of that eminent authority. The varied charms of Nature are aided by the gorgeous enrichments of Art; and the lovelist, however exalted her station, may now enjoy, at all seasons, the beauties of Flora, in a cabinet not unworthy a place in the most aristocratic mansions.—Apply to Mr. NOTTINGHAM, as above.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 172, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public in general to inspection of their various drawings and models, at 172, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient Rench apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

STEPHENSON AND CO., 61, Grocechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their most approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat is well as bottom heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not been in operation, prospectuses will be forwarded as well as references of the highest authority, or they may be seen at most of the Nobility's Seats and principal Nurseries throughout the kingdom.

S. & C. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

TO NOBLEMEN, GENTLEMEN, GARDENERS, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS have received instructions from T. and C. LOCKHART, of the late Firm of T. and C. Lockhart and Burnett, in consequence of a dissolution of Partnership, to submit to public competition, by auction, on the premises at Parson's green lane, Fulham, and at 136, Cheapside, London, (both of which the 1st of September next, the whole of the Life particularly adapted for Nurserymen and Florists, of which further notice will be given.—This valuable Stock consists of a unique collection of BULBS and FLOWER-ROOTS of every description, which has been carefully selected both at home and abroad, during the last 25 years, together with a quantity of the newest and most choice Flower Seeds, well worthy the attention of the trade; a newly-erected Hothouse with boiler and hot-water pipes, a capital brick-built pit, heavy frames, hamlights, six nests of seed-drawers, two desks, two dahl stages, hardy herbaceous and other plants, standard roses, a quantity of box edging, bushel and other measures, a Chubb's patent iron safe, scales, weights, bags, paper, garden-utensils, cutlery, sieves, pots, sundries, &c. &c. &c.

May be viewed one week prior to the Sale, and Catalogues had.

TO FLORICULTURISTS.

SUPERB COLLECTION OF MESSRS. ATT EUPHORBEA, &c. 22, Park Place, Liverpool Road, Islington.

MR. E. E. STONE takes this opportunity to express his regret for the error that occurred in this Journal of last week in naming the day of Sale, it having caused so much trouble to Purchasers, and begs to state that he will SELL BY AUCTION, on the Premises as above, on WEDNESDAY, Aug. 27, at 12 o'clock, the splendid Collection of STOVE AND GREENHOUSE PLANTS, by order of a Gentleman removing; also a capital Tulip Stage, the surplus Household Furniture, a fine-toned 6½-octave Piccolo by Fenchey, and Effects. May be viewed the day prior and morning of sale, and Catalogues had on the premises and the Auctioneer's Office, 93, St. John-street, near Smithfield.

TO BE DISPOSED OF.—An Extensive and Old-Established COUNTRY NURSERY, where a considerable Business has been carried on for many years. Any respectable person with a knowledge of the business would find this concern worthy of immediate attention. Apply to Mr. GEORGE GRAY, No. 23, New Corn Exchange, Mark-lane, London.

N.B.—None but principals will be treated with.

SOUTHAMPTON.—SMALL CONSERVATORY FOR SALE.

TO BE SOLD, A MOST COMPLETE AND MODERN GREENHOUSE, with span Roof and bow Front, 18 feet by 12 feet, with two Stages, Furnaces, &c., and with or without a choice Collection of Plants. The whole the property of a Lady who is remaining.

For further particulars, apply to WITHERS and ROBERTS, Auctioneers, 19, Above Bar, Southampton.

TO BE LET, on Lease of 10, 15, or 20 years, from Michaelmas next, the RECTORY FARM, LITTLE GRANSDEN, containing 300 acres, of which about 250 acres are old and 150 new land; all under-drained.—Apply to the Rev. F. Norris, Gransden Rectory, near Caxton.

LENHAM DOG AND BEAR INN AND FARM.

TO BE LET, and entered upon immediately, That Old Established free licensed Road Side Inn and Posting-house, known as the Dog and Bear, at Lenham. Attached to the premises are convenient stabling, outbuildings, and east-house, and adjoining, are 29 A. 1 R. 15 P., or thereabouts, of excellent arable, meadow, and hop land.—To view, apply on the premises, and for particulars and proposals to let, apply to W. LUCKHURST, Esq., 22, Southampton-st., Bloomsbury-sq., London.

TO THE LOVERS OF PANSIES.

S. WIDNALL, Grantchester Nursery, Cambridge, begs to inform his friends and the public that he has with great care selected his Superior PANSY-SEED, warranted to be all new of the present year, and which he can with confidence recommend. This being a favourable season for sowing, it will be advantageous to those who wish to ornament their gardens with this beautiful flower at a very cheap rate, as packets containing sufficient seed, with careful cultivation, to grow 100 plants and upwards may be had postage free at 2s. 6d. per packet, or three packets for 6s., upon receiving a post-office order.

The Gardeners' Chronicle.

SATURDAY, AUGUST 17, 1844.

MEETING FOR THE FOLLOWING WEEK.

SATURDAY, Aug. 24 Royal Botanic . . . . 4 P.M.

IT is long since we adverted to the DISINFECTION of MANURE, that most important operation, which alone will ever induce people in this country to employ habitually the fertilising materials at their command, or prevent their throwing away money in the pursuit of substitutes uncertain, dear, and comparatively inefficient. It is indispensable to find very cheap methods of destroying the offensiveness of decaying matter, or no stop will ever be put to the enormous indirect waste of national wealth which is now going on.

Among the substances which have from time to time been proposed for effecting this end, some have been dear, like chloride of lime, charcoal, &c.; others dangerous to use, and insufficient, like sulphuric acid; some slow in their action, like gypsum; others too bulky, like peat earth; and others troublesome to employ, as is the case with muriate of lime. Each of these reasons has proved a bar to the employment of such disinfecting agents. But among those which have been occasionally mentioned is one that seems more free than any others from practical objections, and that is sulphate of iron, or what is called in the shops copperas, or green vitriol.

In the year 1842, a Mr. Schattenmann published an account of his manner of employing this substance; and we mentioned his method at p. 191 of our volume for that year. As he is a practical man, and his employment of the salt was on a large scale as a farmer, his observations were entitled to the greater attention. Nevertheless, we do not find that his advice has been much followed; and therefore we beg to invite attention to the following additional evidence produced by Mr. Schattenmann in favour of the use of sulphate of iron:—

"The offensive exhalations produced by putrefying matters arise," says this excellent observer, "principally from the flying off of carbonate of ammonia and sulphuretted hydrogen gas: but if a solution of sulphate of iron is thrown among such matters, a double decomposition immediately takes place; the sulphuric acid of the sulphate of iron combines with the ammonia, and converts it into a fixed salt; the iron combines with the sulphur, and forms a sulphuret of iron. The unpleasant smell of ammoniacal vapour and of sulphuretted hydrogen disappears immediately, and the putrefying matter that is acted on retains nothing more than a feeble odour, which is not in the slightest degree disagreeable."

Now any one may easily verify this fact by taking smelling salts, dissolving them in water, and throwing in some green vitriol; when the fluid will become black in consequence of the separation of the black oxide of iron from the sulphuric acid, and the pungent smell will go off in consequence of the combination of the sulphuric acid and ammonia. In like manner if some green vitriol be dissolved in water, and a stream of sulphuretted hydrogen gas be sent through it, the fluid will become black with great rapidity, in consequence of the formation of sulphuret of iron by the decomposition of the gas; and the disgusting smell will cease to be perceived.

No doubt, then, of the accuracy of Mr. Schattenmann's statement can be entertained, and thus a very cheap and rapid means of destroying foul smells is at once obtained; not indeed so quickly as by the use of chloride of lime, but at infinitely less expense, and quite fast enough for any useful purpose. By this means the most offensive matters may be purified, and putrid substances of the worst description removed without even so much annoyance as arises from common stable manure.

Common sulphate of iron is worth, at the outside, 4*l.* 4*s.* per ton; is not liable to injury by keeping, occupies very little space, and dissolves very readily in water, in which state it is necessary to apply it.

No fear need be entertained of the sulphate of iron, because of its iron, injuring the quality of the manure; experience shows what theory indicates, that it produces no such effect, but that it secures all the advantage anticipated from it, without a single drawback.

We are tempted to introduce this subject into the Horticultural part of our Paper, because in fact, much as it interests everybody, it concerns more especially gardeners, who are either obliged to buy their manure, or, if it is furnished from a farm, are involved in incessant disputes with the farming bailiff on account of it. We advise them to think well upon this article, to disinfect all those offensive matters which are now wasted, and to show the farming bailiff that with hot-water on one side, and sulphate of iron on the other, they can snap their fingers at the farm and all the assistance that is so grudgingly bestowed by it.

"I THINK it a very fit thing," says worthy Master Gerarde, "to adde in this place a rare observation of the TRANSMUTATION of one species into another in plants; which, though it have beene observed in ancient times, as by Theophrastus, 'De Caus. Plant.,' lib. 3. c. 16, whereas among others hee mentioned the change of Spelt into Oates, and by Virgil in these wordes—

'Grandia sæpe quibus mandavimus Hordea sulcis,
Infelix Lolium, et steriles dominantur Avenæ;'

"That is—

"In furrows where good Barley we did sowe
Nothing but Darnell and poor Oates doe growe;

"Yet none that I have read have observed that two severall graines, perfect in each respect, did grow at any time in one eare; the which I saw this yeare (1632) in an eare of White Wheat, which was found by my very good friend Mr. John Goodyer, a man second to none in his industrie and searching of plants, nor in his judgement or knowledge of them. This eare of Wheat was as large and faire as most are, and about the middle thereof grew three or four perfect Oates in all respects; which being hard to be found, I hold very worthy of setting downe, for some reasons not to be insisted on in this place."

What the good Gerarde's "reasons not to be insisted on" may have been, we are unable to discover. Perhaps he was afraid of being laughed at as a dreamer; or, may be, he dreaded an indictment for heresy. Then, it is to be imagined, as now, the doctrine of the transmutation of grain was laughed to scorn; and we have numbered ourselves among the scorners.

But are the scorners right? Are we so *very* sure that one kind of grain has not been formed accidentally from another—that no room is left for argument or evidence? Some years ago we should have said yes; we now say no. We now say that we are not so *very* sure about the matter, although we do still hold hard to the orthodox faith in the matter of species. What has unsettled our belief, and changed us from sceptics into doubters, is the extraordinary, but certain fact, that in Orchidaceous plants forms just as different as Wheat, Barley, Rye, and Oats, have been proved, by the most rigorous evidence, to be accidental variations of one common form, brought about no one knows how, but before our eyes, and rendered permanent by equally mysterious agency. Then, says Reason, if these inconceivable changes have been proved to occur among Orchidaceous plants, why should they not also occur among Corn plants? for it is not likely that such vagaries will be confined to one little group in the Vegetable Kingdom; it is far more rational to believe them to be a part of the general system of the creation.

And then arises the puzzling question of—Where do the Corn plants come from—what country gave them birth—where are they still to be met with in their savage haunts? History says nowhere. The origin of Wheat is wholly unknown; so is that of Oats. Rye is said to occur wild in some of the Caucasian provinces, but that is doubtful; and the Barley which was found by Col. Chesney in Mesopotamia may have been the remains of cultivation. How then can we be *sure* that Wheat, Rye, Oats, and Barley, are not all accidental offsets from some unsuspected species?

A gentleman who lately travelled in Germany was assured, that if Oats are sown early, not allowed to produce ears for the first year, but compelled by artificial means to defer their earing till the second, they will change to other sorts of Corn. A seemingly more monstrous proposition never emanated from the father of paradox. Nevertheless, there could be no harm in putting the statement to the proof. The Marquess of Bristol has done so. At his lordship's request the Rev. Lord Arthur Hervey, in the year 1843, sowed a handful of Oats, treated them in the manner recommended, by continually stopping the flowering stems, and the produce in 1844 has been for the most part ears of a very slender Barley, having much the appearance of Rye, with a little Wheat, and some Oats; samples of which are, by favour of Lord Bristol, now before us. What is to be inferred from this?

But, it will be said, Has the question been *fairly* tried? The mode was this:—A handful of Oats was taken out of a manger, sown in a garden, diligently cared for, and finally reaped. As Oats do not usually consist of a mixture of Barley, Wheat, and Oats, it could not be suspected that any error would so arise, more especially since the Barley that has been raised is not exactly Barley, for it is longer and thinner—nor Rye, for it wants the structure of that sort of Corn. Nevertheless, there is the possibility of error; and therefore the experiment will be repeated with every precaution, and we hope to be allowed to report the result.

In the meanwhile it would be as well if a good many persons would try the experiment in different parts of the country. The question is, Whether by any means Wheat, Oats, Barley, and Rye, can be made to change into each other? The Germans say that it will happen if Oats are sown early, and prevented flowering till the second year. Gerard says that he saw it happen to some extent, though he did not know how. Is this true or not? The cause will come on for hearing at Michaelmas, 1846. Let the country be the jury; and then, "Gentlemen, what say you?" will be our inquiry.

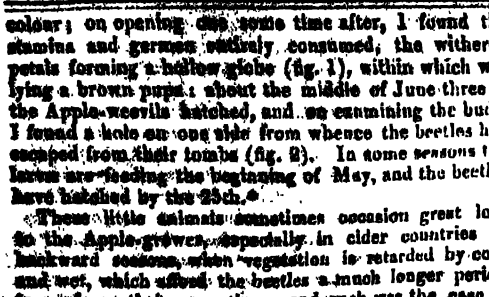
NOTES ON THE CONIFERÆ OF JAPAN.

Abies Jezoensis, Sieb. Tab. 110, p. 19.—This belongs to the Spruce division, and resembles *A. Menziesii* in its glaucous leaves, and most probably is identical with *A. orientalis*, a kind considered by some old writers as only a variety of *A. alba* (the White Spruce of America), but which I imagine, although very much resembling that species in foliage, but not in fruit, is entitled to rank as a species, as it always comes true from seed. It also attains a much greater height, but is never so robust in the trunk as either that kind or the common Spruce. I may here state that the true Abies orientalis of Tournefort is a Spruce and not a Silver Fir, as is stated by a writer (from Nikita) in the *Gardener's Chronicle*, p. 206, 1842, and where the same writer expresses his surprise how I could have stated in the "Gardener's Magazine" for 1840, that it very much resembled the White American Spruce, an opinion entertained by Loiseleur Deslongchamps, who examined the original specimens belonging to Tournefort, and who accordingly published it as a variety of Abies alba; an opinion also entertained by the late Mr. Lambert. I am quite at a loss to know how the writer from Nikita could have made such a statement—he certainly could never have seen either living plants or dried specimens of the true kind, or even consulted any books on the subject; possibly the mistake arose from the writer entertaining the same views as some continental authors, who have attempted to reverse the divisions or subgenera of Abies and Picea.

Abies polita, Sieb. Tab. 111, p. 20.—This is the Abies Khutrow of Dr. Royle, the Abies morinda of Dr. Wallich, and the Picea obovata of Dr. Ledebour. It belongs to the true Abies or Silver section, and very much resembles the common Norway Spruce, but differs in the leaves being larger, and the cones shorter and rounder. It attains a great height, and is now very common in collections, under some one of the above names.

Pinus dasyflora, Sieb. Tab. 117, p. 22.—This belongs to the true Pine section, and has only two leaves in a sheath. In foliage it seems not to differ from that of the Stone Pine (P. pinea), from which most probably it is not specifically distinct; for although in the plate a figure is given of a full-sized cone, which is very small and conical, and very much resembles that of Pinus Massoniana, it certainly must be a mistake, as on the opposite side of the plate the figure of a young cone is given, which represents the true, round shape of that of the Stone Pine. In Japan this kind is stated to attain a height of 40 feet with a clear stem. In Italy the Stone Pine attains a height of from 40 to 50 feet, with the stem clear of branches 20 or 30 feet; and the top forming a kind of parasol. The Stone Pine (P. pinea) is frequently raised from seeds received either from Japan or China, but differs in no way from that of Europe. It has also been raised from seed collected in Arctic America.

Pinus Massoniana, Sieb. Tab. 113 and 114, p. 24.—This kind is not to be distinguished from Pinus pinaster, except in the cones, which are not more than one-fourth the size of those of the cluster Pine. The leaves are in pairs, very robust, and the buds are non-resinous and imbricated. It has been frequently raised from Chinese seed, but not the least distinction can be seen between the young plants and those of the common Pinus pinaster either in habit or foliage. The late Mr. Lambert, in his "Monograph on Pines," considered it as identical with the P. pinaster; and Mr. Loudon, in his "Arboretum Britannicum," adopted the same views upon the authority of Professor Don, who evidently had never seen cones of the true Pinus Massoniana. The Chinese Pine of Mr. Lambert (Pinus sinensis) is a very different kind from P. Massoniana, and has been erroneously published in the "Pinetum Woburnensis," as P. nepalensis; the P. nepalensis of Dr. Royle being the same as P. Massoniana of Siebold.



Pinus parviflora, Sieb. Tab. 116, p. 27.—This is the Siberian variety of Pinus cembra, seldom makes shoots more than a few inches long in the course of the year, and probably will never grow more than 10 or 12 feet high in England, even under the most favourable circumstances, while the Helvetic, or Swiss variety, which is the most common in collections, attains a height of from 30 to 40 feet. The leaves are in fives, and the cones are smaller and longer than those of the Swiss kind.—*George Gordon.*

ENTOMOLOGY.

THE APPLE-BLOSSOM WEEVIL, called *Anthonomus pomorum*.—Last April I received some Apple-buds; the petals had formed globes, but had assumed a rusty

colour; on opening one some time after, I found the stamina and germen entirely consumed, the withered petals forming a hollow globe (fig. 1), within which was lying a brown pupa: about the middle of June three of the Apple-weevils hatched, and on examining the buds, I found a hole on one side from whence the beetles had escaped from their tombs (fig. 2). In some seasons the larvæ are feeding the beginning of May, and the beetles have hatched by the 25th.*

These little animals sometimes occasion great loss to the Apple-growers, especially in cider countries in backward seasons, when vegetation is retarded by cold and wet, which allows the beetles a much longer period to perform their operations; and such was the case in 1815, 1831, 1832, and 1838. Like many other insects in their perfect state, they live through the winter, secreting themselves in the chinks and under the loose bark of trees, beneath stones, clods of earth, &c. In March, when the flower-buds are swelling, the beetles emerge from their retreats, when the males are seen in sunny mornings flying amongst the trees in search of the females, who generally are crawling over the branches, although they are also furnished with wings. They seem to be very careful in selecting proper objects for the reception of their eggs, and on finding a suitable bud, the female bores a hole with her minute jaws, which are placed at the tip of the slender proboscis, until she has reached the parts of fructification, and turning round, she lays an egg in the hole by inserting her ovipositor, and then closes it again with her mouth, and seems as if she were fixing in the egg; this is rather a tedious operation, and is said to occupy three-quarters of an hour; she then hastens to another swelling flower-bud for the same purpose, and is thus employed two or three weeks, viz. until the flowers begin to expand, when her labours cease; for, as the larvæ can neither bear wet nor sunshine, they require the protection afforded by the closed petals. The eggs are hatching from the beginning to the end of April, principally influenced by the variations of the season; if the weather be warm, they are matured in five or six days. During this period the bud grows, and the petals appear of their usual rosy colour, but instead of expanding, they wither, and eventually turn to a rusty brown; and on opening them, in place of the germen and stamina, which have been consumed by a single maggot, one finds rolling about in this globular chamber a grub, of a deep ferruginous colour, which is very sensitive and restless when touched (fig. 4). The maggots are curved, fleshy, and whitish, having numerous segments and wrinkles, with a few short hairs, but no legs; the head is horny and black, and furnished with small jaws (fig. 3). The exact time they remain in the pupa state has not been ascertained, but in about a month from the period when the eggs are deposited the Weevils hatch, and eating a hole through the dry petals, they disperse over the tree, and feed upon the leaves during the remainder of the summer. Like most of the Curculionidæ when approached, the Apple-weevils contract their legs and fall down, so that it is difficult to detect and capture them in any numbers, except whilst they are pairing, or when the females are engaged in depositing their eggs.

The Apple-blossom Weevil was named by Linnæus Curculio pomorum, and it has been distinguished by later naturalists as the Anthonomus pomorum (fig. 5). It is long and oval-shaped, of a reddish-brown colour, punctured, and clothed with short, depressed, whitish and ochreous hairs; the rostrum is long, subcylindrical, curved, and punctured; towards the apex are placed the antennæ, which are slender and geniculated; the basal joint is very long, slender, and clavate—the second is oblong, the six following are more or less globose, and the remaining four form an oval pedicel club; the head is subglobose, with two very prominent little black eyes; the thorax is semi-ovate, truncated before with three indistinct stripes of a pale colour; the scutel forms a white dot; the elytra are elongate-ovate, with nine punctured striæ on each; beyond the middle is a large obscure lunar patch, bearing a pale slender stripe across the centre, forming an angle at the suture, and towards the apex are two oblique spots; wings very ample; legs moderately long and ferruginous; anterior tibiæ curved, with a strong tooth beneath—the others are slender, but smaller; the anterior tibiæ are finished internally, and they are all terminated by a claw; the tarsi are 5-jointed, the third joint being bilobed, the fourth furnished with minute claws. The smaller figures denote the natural or usual size of the animals.

The whole of the beetles will also lay their eggs in the blossom-buds of Pear-trees, and it is on calm days the females are most interested in depositing them; for in windy or frosty weather they retire to sheltered situations. In genial weather, from Messrs. Paul being on the blossoms open in a week or ten days, from 8 till 5. These weevils do little mischief; but in cold, damp seasons, when the buds are three weeks or more in expanding, scarcely an Apple-blossom sometimes escapes. The best mode of destroying them is to gather the punctured withering flower-buds and burn them, by which means the larvæ and pupæ will be cut off, and the beetles may be collected by beating the branches over a net; but unless this be done as soon as they make their appearance, it will not be of much service, as the eggs will have been deposited. From various statements it seems that the females will not readily fly, and as they crawl up the trees, their incursions may be stopped, and the crops saved, by winding tarred bandages round the upper portion of the trunks.—*Rusticola.*

* See Curtis's Brit. Ent., fol. and pl. 562, where directions for the genus and species will be found.

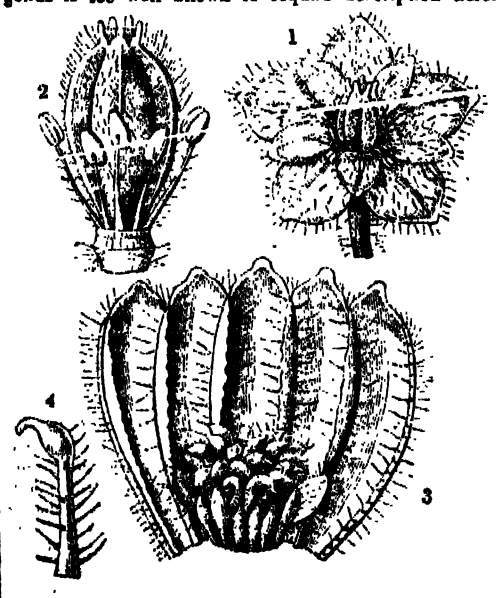
ON THE HYSSOP OF SCRIPTURE.

At the meeting of the Royal Asiatic Society, on the 15th of June, a paper was read by Professor Royle, on the plant which he thought was the Hyssop of Scripture. Having so recently read a paper on a kindred subject, the author referred to it for the principles which should guide, and for what should be considered as proofs in such investigations; and stated that in this, as in the case of the Mustard-tree, he had been led to the discovery from the similarity of the Hebrew name to one occurring in the lists of drugs in the writings of the Arabic writers on Materia Medica. Dr. Royle then proceeded first to enumerate the passages of Scripture in which Hyssop is mentioned: first, in Exodus, ch. xii. v. 22, where the Israelites are directed to take a bunch of Hyssop, dip it in blood, and sprinkle the lintels and posts of their doors; second, in Leviticus, ch. xiv. v. 4, 6, and 52; and Numbers, ch. xix. v. 5, where Hyssop is directed to be used in the ceremonies of cleansing the leper, and for sprinkling the water of separation. To this ceremony reference is made in Hebrews, ch. ix. v. 19; thirdly, Psalm xli. v. 2, "Purge me with Hyssop, and I shall be clean;" fourthly, 1 Kings, ch. iv. v. 23, "And he (Solomon) spoke of trees from the Cedar that is in Lebanon, even unto the Hyssop that springeth out of the wall;" fifthly, The last mention is in the crucifixion of our Saviour, John, ch. xix. v. 29, "And they filled a sponge with vinegar, and put it upon Hyssop, and put it to his mouth." Matthew and Mark in mentioning the same circumstance, state that the Hyssop was affixed to a reed, or small stick. From these passages the author inferred that any plant answering to what was required, should be found in Lower Egypt, in the Desert of Sinai, in and near Jerusalem, grow naturally on rocks or walls, and be large enough to yield a stick, and be supposed to have cleansing properties, and have a name in the Arabic or vernacular languages similar to the Hebrew name. Numerous plants have been brought forward as the Hyssop of Scripture, but none of them possess all the above requisites. Some authors have adduced Mosses and Ferns, others the bitter Artemisias; but the greater number have considered some sweet herb of the family of Labiate plants, to be the Hyssop of Scripture. The Artemisias are probably the only plants which are found in all the above localities, but they do not grow upon walls; and of the Labiate plants, the Rosmary is the only one large enough to yield a stick, and we do not know any species which grows upon walls, and is found in all the required localities. In attempting, however, to identify the Hyssop of Scripture, it is necessary, the author observed, to know the names by which it is designated in Hebrew writings; in these it is written both *Esob*, and *Esobh*, and *Esof*; and in the Chaldee version, *Esofa*. Dr. Royle then stated that his attention had been drawn to the subject from observing in Rhases that there were two kinds of Hyssop, one of them growing on the mountain of the Temple, that is, Jerusalem; and this, in connection with Burckhardt describing a plant called *Asuef*, which he found in several wadies about Mount Sinai, creeping up the mountain side like a parasitic plant, its branches covered with small thorns. From the name and description, Dr. Royle inferred that this must be the Caper plant; and on investigation found that *Asuf* is one of the well-known names of this plant, as may be seen in the "Camus," also in Richardson's "Arabic Dictionary," and in the "Ulfaz-Udwieh," &c. The similarity in name being sufficiently great, the author proceeded to show that the plant corresponded in a number of the necessary requisites. Thus the Caper plant is well known to be indigenous in Lower Egypt, Bové found it near Mount Sinai, also on the ruins in the neighbourhood of Jerusalem, as has been done by others. That the habit of the Caper plant is to grow on rocks and walls, is too well-known to require to be proved. Hence we learn that: the *Asuf* has the habit, and is found in all the situations where the *Esof* must have been indigenous for the Israelites to obtain it. That it possessed, or was supposed to possess, cleansing or detergent properties, may be seen in the account of its properties from the time of Hippocrates to the present time. Pliny says it is useful in a skin disease nearly akin to leprosy: in the cleansing ceremonies for which *Esof* was employed by the Israelites. It has long formed one of the "Cathartica radices quatuor aperientes minores," or the five lesser purgent roots. It holds a place in some of the Continental Pharmacopœias, and is universally esteemed in the East. It remains only to see whether the Caper plant would yield a stick long enough for a man with his hands tied to reach up to the sponge to raise the sponge filled with vinegar to the lips of our Saviour. The cross, to be sure, is said to have been low, but not very low, for it is said that the feet of our Saviour were not raised, and therefore, an ordinary-sized Caper would be long enough for the purpose. Such a plant, a shrub like the Caper plant, growing in a congenial climate, would be able to yield, as Pliny describes the Capparis as a shrub of a hard and more woody substance. Hence, we have seen that the Caper plant has an Arabic name *Asuf*, similar to the Hebrew *Esof*,—is found in Lower Egypt, in the deserts of Sinai, and near Jerusalem—grows upon rocks and walls—was always supposed to be possessed of cleansing properties, and is large enough to yield a stick. Dr. Royle, therefore, concluded by stating, that as he could not conceive it accidental that all these circumstances are united in this plant, as they must have been in the original *Esof*, he must consider it as proved that the Caper plant is the Hyssop of Scripture.

Home Correspondence.

Watering bedded-out Plants.—I am rather astonished to find such serious complaints about the season for flower-garden purposes. I imagine that it has been much the same in all parts of the kingdom, and the only serious ground of accusation appears to be the drought. As far as my experience goes, however, I much prefer a dry season, if warm, than one in which heavy rains predominate. As, however, in a dry season watering is indispensable, and as in this, like most other processes, there are various modes as well as degrees, it becomes a matter of some importance to inquire which is the best. The importance of bottom-heat is now pretty well understood: it is also admitted that moisture is a heat-carrier. In the face of such facts, then, I cannot conceive how it is that evening watering should be so much persisted in out of doors. A great deal of the weather we experience through the months of May and June in each year, consists of sunny days with cold nights. Now, one of the most important measures to adopt in this case would be to arrest radiation by some covering; but as this is expensive, it is not to be generally recommended. However, if we cannot shut in the heat, we ought not to take active means to disperse it. There are, it would seem, two distinct objects sought to be obtained by watering in general:—The one called a thorough watering is, of course, intended to facilitate the decomposition of organic, and enriching matters in the soil, and to fill the tissue of the plant with fluids; and the other such as we apply to cuttings, &c., and designed merely to prevent excessive and debilitating perspiration from the leaf. Now, I contend (and from long experience of the matter) that this latter mode of watering is the true and most eligible one for flower-gardens, in which the great majority of mass plants are natives of intertropical climes than we can boast in Britain. As a question of bottom-heat, too, it will be admitted that it is only by slowly progressive accumulations that the temperature of the earth advances from the freezing point to 70° or 80° in summer. This accumulation, then, in the case of acclimatising, should not be too rudely dealt with; for I make little doubt that a heavy watering after a bright sunny day, will at any time rob the earth of 5° in the course of a few hours, more especially if the day has been calm; on such days the bottom-heat accumulates with great rapidity. Early morning watering, then, will be found the most eligible by far for flower-garden purposes in general, except perhaps in July and August. Moreover, the watering of newly-planted masses should not be intrusted to men who have only one idea, *viz.*, that of drenching. If the waterer will give the beds as much as will meet the demands of the plant through that day it is enough. Much depends on the way in which plants are transferred from pots into beds; plants taken from the cutting-pit only a few days previous must be expected to undergo a severe stagnation, if transferred to the beds before undergoing a gradual hardening process. This may often be perceived in such plants as the Heliotrope or the scarlet Pelargonium; the leaf of the Heliotrope frequently assumes a dark-purple hue from this sudden change. Cuttings should not be struck in a temperature unnecessarily high for stopping out. Nothing is gained in the end by such hurry. All single plants on elevated beds should, when planted, have a small basin hollowed in the soil round the stem; as the consequence is, the ground becomes battered by the application of so much water, on account of the convexity of surface, and forming ready channels to the side of the beds, escapes without conferring any benefit.—*Robert Errington.*

Flower Garden.—I can bear testimony to the gay appearance of the Flower-garden at Tandridge Court, and I believe what Mr. Cleak states to be true, viz., that he has dispensed with the *watering-pot*; but he should have mentioned that the Flower-garden at Tandridge Court was formerly a morass abounding with springs, but was filled up about eight years since with good sandy loam; at that time a precaution was taken to drain it, and consequently it became so wet, and damp that the turf had to be removed, and gravel walks with Box-edging substituted in lieu of the turf. It also, at the same time, underwent a thorough draining. Now there is no need for the watering-pot where sufficient moisture exists, as it well known to be the case at Tandridge Court. Since visiting Tandridge I have seen the Flower-garden at Barron Green, the seat of C. Masters, Esq., and I was agreeably surprised to find it quite a mass of beauty; on inquiring of Thompson, the gardener, told me that every bed had been copiously watered every evening, and that he found it quite requisite, for when water was withheld the plants lost their vigour.—*W. H. M., Godstone, Surrey.*—Another correspondent adds—"A writer in the Calendar lately has justly remarked that "this has been a trying season for gardeners;" for instead of the air parting with its moisture to vegetation, it has been making a continual drain upon the leaves; so much so, as to prevent newly turned out plants from producing either roots or branches. This, I dare say, most gardeners are aware arises from an insufficiency of moisture in the air compared with its power of carrying it. This



is owing to the current of air coming from the north-east, or out of a colder latitude, and passing over a warmer surface as it approached us, which caused it to ascend, becoming expanded. During the time that the north-east wind prevailed, it was no uncommon thing to see, just after sunrise, clouds portending rain, dissipated in a very short time. When the wind shifted to the south-west, we imagined vegetation would be all right; from the circumstance of the current of air coming from a lower latitude, descending and condensing as it reached us; but such was not the case, as the great heat the earth had attained, caused a powerful surface action sufficient to prevent the deposition of moisture; and it was not until contrary currents of air cooled down the atmosphere, that rain fell, and vegetation made any progress. How far we shall profit by the experience of the past season I cannot say; but I consider that "W. P. A." is entitled to our thanks for his judicious remarks. "E. C." speaks of a flower-garden being in beauty about the first week in August; but it is a very different thing to have it in perfection about the latter end of June and beginning of July. This, I apprehend, is what "W. P. A." alludes to; it is what I have been accustomed to see in other years. Had "E.C." mentioned a few of the plants he saw, and also said something about their arrangement, it would have considerably enhanced the value of his statements.—*C.*

Pine-Apples.—In a late Number, "M. S.," replying to an article of mine on the Fruiting of the Pine-Apple, states that I have said, "Queen Pines showing fruit in August would ripen fruit by the end of October." On referring to my MS., I find it there written "the end of November." I noticed the mistake in the article when it appeared, and I beg to assure "M. S.," if it is was written October in my communication, it was an error of mine, but at the time I imagined that it was a misprint. I may mention that, with houses properly constructed, it is quite practicable to ripen the Queen-Pine between the time of showing fruit in August and the end of November.—*James Roberts.*

Thornfield Pines.—A trip to Thornfield has afforded me the pleasure of spending an hour with Mr. Hamilton, and I can add my testimony to the great excellence of the peculiar plan adopted by him in the fruiting of the Pine, as shown by the beauty and size of his fruit. In my opinion, Mr. H. is anxious to have for his principles of culture, "a fair field and no favour;" and certainly if the practice, in the hands of others, proves equally successful, he may with full assurance look forward to the period of the great object of his wishes being attained. Such instances of persevering industry, and singleness of purpose, merit the favourable consideration of all.—*A. B. C.*

Planting Pines in Tan.—The remarks of "Judex" have induced me to add further testimony with regard to the bad effects resulting from planting out Pines in tan. I am exactly in the same predicament as "Judex." After consulting Mr. Hamilton's Treatise on the Pine, I planted out nearly 100 fine succession plants in new bark, similar to what Mr. H. recommends; to my dismay, however, the plants all showed fruit in a few weeks afterwards, and on examination I found that instead of making roots in the tan, they had nearly lost all they had. The tan was slightly dried before being put into the pit, and it had a nice heat in it when the plants were put out, as well as all the time they remained in it; in fact, I never paid so much attention to anything as I did to this pit of Pines: I watched them morning, noon, and night, and I am sure that the fault does not result from any mismanagement, but is wholly attributable to the tan.—*Hannibal.*—Another correspondent writes as follows:—"I visited Thornfield lately, and I am not surprised that Mr. Hayward should have considered the Pines that are planted out to be a year older than those in pots, for their appearance fully justifies that opinion. With regard to the statement of "Judex" that tan "is considered to possess no fattening power," I imagine the following instance will justify a different opinion. I had a seedling Fig in a 60-sized pot, which I plunged in a bark-bed, and to my surprise, when I came to lift it for re-potting, I found that it had pushed its roots through the bottom of the pot, so far into the bark, that after I had shaken the loose bark off there remained a mass of roots firmly matted together as large as a No. 12-sized pot. If any doubt this I would advise them to visit Thornfield, where they will find Mr. Hamilton willing to give every explanation of his mode of culture, which I have no doubt will in time entirely overturn the old system of Pine growing.—*G. Blackburn, Dewsbury.*—A third writer remarks:—"I have long been a practical gardener and a Pine-grower, but I have never seen Pines equal to those at Thornfield; they are grown on suckers attached to the old plant, and I have myself seen two fruit cut from the same sucker in one year; the second fruit ripened in the middle after the first was cut. A plant of Jamaica, which bore a fruit in December last, is now ripening another fruit, which, in all probability, will be ready for cutting at Christmas. I am quite convinced that if properly carried out, in a short time Mr. Hamilton's system will be generally practised; and why should it not? Where the necessity of fruit of superior quality can be produced in the same space. I nowhere read in Mr. Hamilton's Treatise that leaves and tan are recommended; Mr. Hamilton's system does not at all depend on whether or not the plants into the tan come are planted in compost, and some are in pots, but the greater part of them are in pots; those that are in tan, however, have made twice the progress of those in pots; but the fruit that I above allude to are produced by plants growing in soil.—*J. C. Turner, Stockport.*—A fourth communication says—"Judex" (p. 589), who states that he has been acting under the advice given in Mr. Hamilton's Treatise on the Pine-Apple, turned out into tan, or rather into tan and decomposed leaves, mixed and laid up in a heap which had been at work six weeks, 24 fruiting plants. He writes that the tan was just to give life to the mass, and adds that such a compost is just what Mr. Hamilton would have selected himself. Now, I would inquire in what page of my treatise he discovered such a compost recommended? Had he communicated to me his intention of differing so widely from what I have recommended in my Treatise (see pp. 58, 73, 66, and 193), I could have informed him what the result would have been, namely, that three parts decomposed leaves to one of tan would act like leaven, souring the whole lump as soon as fermentation commenced; and it appears that it had been put up in a heap for that purpose. It is wrong to charge me with having recommended such a compost. If "Judex" has ever read my Treatise, he must have remarked my caution against the use of impure tan, as well as of other composts. Has "Judex" used the same compost which I have recommended for tanks? If he has not, I shall not be responsible should that also prove a failure. My plants which fruited in last December are now swelling another fruit; a fact that can be proved by persons of the highest respectability, and whose veracity no one will question. Mr. Barnes's excellent remark, p. 31 of this year, is worthy of perusal. He uses sweet pure composts, similar to what I employ myself. "Judex" justifies himself by cautioning the readers of the *Chronicle* against—not the compost which I recommend, but his own bad material, of which he is the inventor. If he will visit Thornfield soon, he shall have ocular proof of the advantages of planting out Pines in tan, both with regard to plants and fruit; and I dare state that the largest fruit he ever saw, according to the size of the plant, is now ripening on my improved mode of planting in tan. The most of my fruiting plants, however, are growing in a mixture chiefly composed of soil similar to that recommended in my Treatise, and such as I will always recommend where the tank system is used. I imagine we are only learning to cultivate the Pine; every succeeding year adds something new to our experience. In conclusion I would state, that any Pine-grower adhering strictly to my system, may with ease perfect one fruit every year from the same plant. I have formerly, and still do, cut three fruit in two years from the same plant.—*Joseph Hamilton.*

Morphology.—Monstrosity of Ceratium.—The curious illustration of Morphology which is sent with this note was found a few days since on the banks of the river Wye, near Tintern, and seems to be of sufficient interest to deserve notice in the *Gardeners' Chronicle*, as illustrating those sound scientific views which have recently appeared in that Journal. The usual structure of this genus is too well known to require description here.

Explanation of the Magnified Figures.

1. An expanded flower. 2. The ovary and stamens. 3. The ovary cut open, showing the ovules. 4. An ovule.

In the present plant it will be seen that the petals and sepals have quite taken upon themselves the appearance and structure of leaves, and that the germen also clearly shows that it is formed of five leaves, attached to each other by their edges. The following is a description of these curious flowers:—Sepals 5, green, hairy, distinct, spreading, oval, differing from the uppermost leaves only by being broader in proportion, and smaller, and having a membranous edge towards the end; petals spreading, and quite similar to, but smaller and rather narrower than the sepals; filaments of the stamens covered with hairs like the leaves; anthers unchanged; germen covered with hairs, green, oblong, with five ribs and furrows, tipped with five minute yellow points, and only slightly connected at the top; ovules apparently abortive. In these specimens we see what must be a demonstrative proof to all unprejudiced minds, that the sepals and petals do not originally differ from leaves, but are the same organ adapted to the performance of a different function; and also, that the germen is nothing more than several similar leaves (for, if separated and spread flat, they differ solely in size) placed together in such a manner as to form a pouch, to include the ovules, and assist in their development into seeds. There were numerous specimens possessing this interesting structure. The soundness of the morphological views held by scientific botanists is now so well established by the numerous instances of different organs reverting to their original type, which have been brought to light, as not to require my advocacy in this place; still, it would appear that there are persons who so misrepresent, or perhaps misunderstand the facts, as to suppose and state that those who hold them are not as full and firm believers in the superintendence of a Divine Providence, and know as certainly that everything in Nature is perfectly adapted to perform the functions for which it was created, as they are themselves. To such it can only be said, that the unprejudiced search after truth cannot fail to produce a fervent admiration of the Divine power and wisdom that is displayed in the creation.—*Charles C. Babington, St. John's College, Cambridge.*

The Gray Wagtail.—Some of your readers may be pleased to hear a little more of the gray wagtail, an account of which appeared in your columns on the 21st of last October: they may like to be informed what became of it, and whether I succeeded in discovering the object of its visits to my house. I am still unable to say anything decisive on the last point; I had the window washed as I proposed, but this made no difference, the bird coming as before. Once it was seen to pursue an insect, which it caught, after alighting upon the ledge; but such a solitary instance cannot prove anything. Several windows were occasionally visited, though the first continued the favourite. After a while, we became so much accustomed to the tapping, that it scarcely excited our attention. I have learnt that two other houses in the parish were in the course of the winter visited in the same manner, and at one of them a little alarm was felt by some persons who were disposed to be superstitious: but it seems difficult to account for the appearance of so humble a creature causing alarm to any one. When I wrote before (early in the month of October), I stated that I had not observed any more wagtails of the same species about, but others arrived afterwards. Still, I believe it was throughout the same individual that visited us; and I form this opinion from having often seen my feathered acquaintance stop at a particular spot (the shallow water alluded to in my former notice), both when going to and returning from the house; and I never perceived but one in that haunt, though in other places there used to be more of these wagtails together. For the same reason, I conclude that, as our visitor came here the first, so he remained the last of this kind; I noticed one bird for some time after I had lost sight of the others, and that one frequented the haunt aforesaid. Bearing made his adieus to us at the window on the 16th of February, but he lingered in the village another fortnight; I saw him on the 1st of March, soon after which he must have commenced his journey to the north. When he left us he had not changed his dress, but doubtless he long ago put on his best suit. I trust he found a constant mate, and made a pleasant home, and if he has a family, that they are all doing well. Should he visit us again in the autumn, he shall have a welcome; and I hope he will then come somewhat less sarcastic in his looks.—*S. Warnford.*

Coniferous Plants.—Could you not direct the attention of some practical botanist to writing a little manual on the nature and habits of Conifers? A small work like Rivers' "Rose-fancier's Manual" would answer the purpose admirably; and the smallness of its price would bring it within the reach of every one. The information chiefly required is a detailed account of each variety, to what climate and country it naturally belongs, the quality of the timber, and in what description of soil it attains the greatest size. Mr. Selby, in his admirable work on British Forest-trees, speaking of the new varieties of this tribe, begs of gentlemen not to content themselves with merely planting them in pinetums and shrubberies, but to give them a fair trial among other forest-trees. We shall never know which of them are adapted to this country so long as we only plant them in the shrubbery—always the driest and most sheltered spot about the place, and where the gardener carefully shades them from the snow and winter blast. If we wish to find what they are really worth, we must put them out in our plantations, and a very few years will show which of them are likely to be acquisitions, and which are not. Some may thrive very well in a shrubbery, when protected from the snow; but be quite unfit for bearing up against a long continued storm, with their branches bowed down with six or eight inches of snow upon them. Others may do very well when sheltered from the wind, but be brittle and apt to snap over when exposed to sudden gusts. Varieties with both these faults may thrive for years in a pinetum, and yet be worthless as additions to our forest-trees. I was delighted to see in the *Chronicle*, some weeks ago, that an Irish gentleman had taken the matter up in this light, and had made a plantation of 11 acres of Deodar. If other planters would follow his example, we should soon know practically the merits of every new variety. I intend doing the same this next winter, and am now busy fencing and draining the land for a plantation of Scotch Fir and Larch, among which I shall plant as many seedlings as I can get of *P. cembra*, *P. gerardiana*, *P. excelsa*, *P. laricio*, *P. pallasiana*, Deodara, Morinda, Araucaria imbricata. The only protection they will have will be a few Oaters round them, to keep off the rabbits and hares. As the ground on which they are to be planted is a high open upland, about 1000 feet above the sea, it will be a sufficiently severe test as to whether they can stand our winters or not.—*Waldeve.*

Bees.—In reply to a "Would-be Lover of Bees," respecting the attack made on him by those insects, I beg to suggest as a preventive that he should provide himself when near his hives with a veil composed of stiff muslin, fastened right round the band of his hat, and beneath his chin, and tightened round the bottom of his coat; this will certainly prevent the being stung on the most tender organ, or any other part of the head. If a "Would-be Lover of Bees" had, immediately on his extracting the sting, gone to his flower-bed, and applied the bitter part of that vegetable, the walnut, he would have found greater protection against, might have appeared both at church and market, and have had no occasion to complain of the want of an antidote for the unpleasant attack. I have a great quantity of bees under my care, on the Canadian system, which are tolerably vicious; and I have adopted the foregoing plans with complete success. —*Tyro.* [Another correspondent, signing himself "Apis," confirms the above statement. A still better guard, however, is a fencing-mask.]

Bees.—I wish I could afford "A would-be Lover of Bees" the means of rendering himself more agreeable to those insects. Washing the face and hands, and rinsing the mouth with vinegar prior to approaching them, are generally considered most effectual. As respects the application of volatile alkali, by which I mean what is usually called *spirit of hartshorn*, I wish it had been stated how long after the wound was inflicted the alkali was applied. The venom of the bee is so quick and so diffusive in its effects, that the utility of the remedy (which I have always succeeded with) depends upon the promptitude with which it is applied.—*Edward Bevan, Esquire, Dyan, near Mold, Montgomeryshire.*

Heaping Earth over Roots.—A correspondent having obligingly informed us that he knew of a Mulberry tree over whose roots earth had been heaped without injury to it, a wall being built round the stem, we requested further particulars, in consequence of which we have been favoured with the following:—The Mulberry trees were planted in the autumn of 1816, and then measured between four and five inches in girth; the lowest branches shot forth six feet from the ground. The soil is a rich mould, to which was added at each spot a large cart-load of mortar rubbish well mixed in, and forming a circle of 10 feet diameter; and great care was taken to plant them at exactly the same depth as when taken from the nursery, and to arrange and secure the roots so that they might extend on all sides. In the sixth year they produced a very handsome dish of remarkably fine fruit, and in every succeeding year there has been an increased produce. In the year 1832, when the garden was enlarged, the soil required to be considerably raised; and to prevent the accumulation of fresh earth injuring the roots, a foundation wall was built round each tree, six feet in diameter and three feet in height; a tiled drain was made from one wall to the other, and carried on to take off the sucked water, which it does effectually. Many persons predicted the death of the trees from the great weight accumulated over the roots, and the exclusion of the sun's warmth, but they have continued to flourish even more than before, bearing fruit abundantly and making shoots yearly which average about 10 inches. It must be remarked that the wall was built on the original surface, without in any way disturbing the roots. The measurement of the trees at three feet from the ground is at present three feet in circumference. Several of the branches at three feet from the body are 18 to 20 inches in circumference. The top covers a diameter of 20 feet. The earth, which was applied to the roots in 1832 was gradually sloped down, therefore no exact diameter can be given. This is the substance of the account received from my friend. He says the idea was entirely his own, and I trust say it does him great credit. I cannot see why it may not answer as well with trees of a larger size and of course greater age.—*M.* [In this case—1, each well was connected with other wells by great drains; 2, the soil was very loose, in consequence of old mortar having been freely intermixed. Hence air had peculiarly ready access to the roots. It appears moreover, that the earth which was heaped up, was shaped away towards the circumference, and our informant does not know to what extent that took place. But this is a most important point; because it is only the roots at the circumference that are much affected by the superincumbent earth; and if it were pared away much they would not be conscious of its presence.]

Glycine sinensis.—Although it is now nearly 30 years since this elegant twining plant was introduced from China, it does not appear to me to be so generally cultivated as it deserves. What this is owing to I cannot pretend to say, as few plants are more easily propagated, or present a finer appearance in early spring, when loaded with its long drooping clusters of lilac-coloured flowers. The usual mode of increasing it is either by cuttings of the roots, or by layering, in small pots plunged in the earth, the young shoots whilst making their summer growth, and which are found to emit roots at every joint. On looking over some old memoranda lately, I met with the following particulars respecting the striking of the Glycine from cuttings. Perhaps they may be interesting to the readers of the *Chronicle*, and be the means of increasing the culture of so desirable a plant. Cuttings taken off at this season strike more freely than when made in the spring. The shoots best adapted for the purpose are those which have become firm and hard, but not too woody. In preparing the cutting, two eyes are all that are necessary to be left on each. Out of two pots containing 100 cuttings prepared in this manner, and inserted in pure silver sand, such as is generally used in the neighbourhood of London for striking with—only 5 died. They were placed in a moderate hotbed on the 20th of August, 1829, and in the course of three weeks were found to have made roots from 3 to 4 inches long, although scarcely any difference was observable in the appearance of the bits, excepting that they had swelled a little more than when put into the pots. Six weeks afterwards they were potted off into small pots, and preserved during winter in a common frame. The following spring the greater number of them sent out shoots from the upper eye, and others from the one at the bottom of the cutting: a few remained dormant until June. From the whole it appears there is little difficulty in striking the cuttings of Glycine sinensis, and this circumstance, I hope, will induce many to make the experiment. I readily admit that as a garden plant the Glycine is common, but it is as a twiner for decorating the porches and walls of cottages and lodges that I should wish to see it more extensively employed. Every one who has seen the fine specimen in the Horticultural Society's Garden at Chiswick, when in blossom, must have been struck with its beauty. In 1834 it covered a space of 800 superficial feet. Being against a south wall, the flowers remain a shorter time in perfection than when trained against a wall with a south-east, or eastern exposure. The latter shows it to great advantage, as it is later in coming into blossom, and the colour of the flowers is not so liable to be injured by the sun.—*M. E. H.*

Sports.—I have now in bloom a plant of Menziesia polifolia stricta rubra with red and white spikes upon the same branch; it has flowered so for the third summer.—*F. X. O., Cliff Vale.*

Preservation of Seed.—We have just received some seeds of the Nutmeg-tree (*Myristica moschata*), sent to us by Mr. Lockhart, of Trinidad. They were removed from the pulp and mace, packed in moist Moss, and closed in a tin box almost hermetically. They have germinated during the voyage and thrown out a radicle and a plumule to the length of an inch or more each, and apparently could not have come in a fitter state for planting with a prospect of their success. Surely the seeds of Victoria might thus be sent by some of our South American friends.—*W. J. H., Kew.*

Tropæolum canariense, &c.—The flattering notice in your columns last year (p. 573), respecting the cultivation of this, by Mr. George Davidson, has induced him this year to redouble his exertions; and notwithstanding the drought and prolonged easterly winds he has had to contend with, he has produced about six of the most splendidly-grown specimens of this plant which I have ever beheld, and which are alike creditable both to his zeal and ability. This year he has planted two plants for each mass, and he has thus procured such a dense profusion of foliage, that the whole framework round which the plants are trained is in some instances entirely concealed; and moreover the leaves at the bottom of the stem are so profuse, as thoroughly to prevent all nakedness of appearance near the roots. The plants have been sown in a rich compost of decayed leaf-mould and other matter, and this has not only acted as a powerful stimulant in their growth, but has greatly improved the size, vigour, and freshness of colour of the leaves and flowers, as any of your London readers will perceive if they will visit the western end of the long garden walk, now well deserving the name of a garden—may it ever continue so! The public are not aware of the interest taken in these grounds by those employed in them. Mr. Edwards, the chief superintendent, most liberally supplies (from his own garden), pipings from his beautiful Carnations, and the best seedlings from his Heartsease, while Mr. Baxter, the able superintendent of the greenhouse department, is indefatigable in raising cuttings and seedlings in frames of his own construction; such zeal and activity, such hearty good-will, are surely deserving of all praise. To such of your readers as have ponds in their grounds, or any pools of ornamental water stocked with fancy water-fowl, it may not be uninteresting to know that Mr. Baxter greatly improves the growth of his flowers and plants by using the home-made guano he collects himself from the margin of the round pond, where the geese and other birds yield him a very good supply, till lately never turned to any account, or thought to be of the slightest use, either to the gardener or any one else. To the poor, who live on commons where geese are plentiful, this hint may suggest a profitable employment of their children occasionally, for during an entire winter they might collect a considerable quantity, either to sell or to add vigour to their spring operations in their homely gardens.—*James Maugles.*

Hallett's Fertiliser.—Having heard of Dr. Hallett's Fertiliser, I this spring sent for one ton of it, and from what experience I have had with it, it has given me general satisfaction. I have been experimenting with various kinds of manures, but the Fertiliser proves itself to be superior to all of them in causing plants to grow rapidly. I sowed some early stone Turnips on the same day, and on the same piece of ground, side by side. Those manured with the Fertiliser are now nearly taking up, while the others, dressed with bones and farm-yard manure, are just commencing to form roots. The ground dressed with the Fertiliser has always been remarkably moist during the whole of this dry season. We have had no rain here from the 2d of March until St. Swithin's Day. I have tried the Fertiliser with advantage on Potatoes, Pelargoniums, Cape bulbs, Heaths, Dahlias, &c., as well as on vegetables of all kinds. For plants in pots I dilute it in liquid state; I have also tried it with equally good effect on Vines and on Melons, which promise well. About two years ago I planted a group of evergreen Oak, in pots, and during last year they made shoots 3 or 4 inches long; this year I shifted them into larger pots, I watered some of them with the Fertiliser, and they have made shoots 3 feet in length; whilst others, watered with pump water only, have not made shoots more than 6 or 8 inches long; they have both received precisely the same management in every other respect. To any one who may be disposed to call, I shall be happy to show the results of my experiments.—*John Wills, Guernsey.*

Manures.—I observe in the *Chronicle* remarks on the great value of nitrous or nitrie compounds in manure. Now we know that the French, when driven to it by necessity, in the beginning of the late war, contrived to form nitre beds, and to furnish themselves with sufficient for making gunpowder. This process is in English (*vide* Dr. Ure's Dictionary of Arts, p. 860), save all of them nitre beds. Might not every farmer in this country have his nitre-bed, in the same way as gardeners have their mushroom-bed?—with this difference only, that when earth has once acquired the chemical tendency to produce nitre, it does not cease to be regular when watered, but still retains sufficient of the power (if I may so call it), to attract the proper ingredients from the air. May not the true theory of compost be, that they are in fact very weak nitre-beds? This appears to me a subject worthy of your attention, and an article now and then on the best mode of making the beds, might do good, and above all lead to the general preservation of that most invaluable article household urine, which, I apprehend, would be found (together with soap-suds), one of the best ingredients of the nitre-bed.—*Horticola.*

Local Horticultural Societies.—At p. 525, there is an appeal from a "Gardener, Dartmouth," severely reflecting on the Torbay Horticultural Society. Had your correspondent made more particular inquiries before writing such unfounded aspersions, its veracity might have escaped the severe check it must now encounter. No jobbing gardener of Dartmouth gained an extra prize at our last Exhibition for Martynia fragrans. The plants in question, the property of the Hon. Mrs. Hare, Gunfield Lodge, were so said by the Exhibitor, and had attained their high state of perfection under his care and attention. They were exhibited through the kind permission of Mrs. Hare as decorative plants; and were awarded an extra prize by the special permission of the committee, because the Judges considered them the best-grown plants in the room.—*The Secretary of the Torbay Horticultural Society.*

Labourers' Shows.—Will you permit me to suggest that Shows may be very beneficially made for the poor, where neither funds nor supplies can furnish one for the rich? I came into this parish about 12 years since. My labouring classes were very inefficient gardeners. I considered that a Show of common fruits and vegetables, with small prizes, would excite their attention. For this purpose I published a list of rewards for such exertions; and as I had obtained two pieces of land to let out in allotments, I gave prizes to those who cultivated these with the greatest care. The effect has been prodigious. The articles brought to the first Show would have excited your smiles; those now brought, your commendation. My cottagers may compete with most of their class—all the result of this simple measure. Several of my wealthier neighbours have kindly sent specimens of fruits, &c., to lay on a side or honorary table. From these my poor people learned to know what skill and industry could effect; they have attempted similar things, and with success. I inclose a list of the prizes I annually offer. We can only make one Show in the year; July is considered the most suitable month, and the day is fixed earlier or later, as the season is forward or backward.

	£.	s.	d.
To the occupiers of the best cultivated allotments in Dunda's Flat and Sadler's (each)	0	5	0
To the occupiers of the next best cultivated allotments (in each of the above)	0	2	6
For the best plate of early Potatoes (six in number)	0	2	6
For the next best	0	1	0
For the best summer Cabbage	0	2	6
For the next best	0	1	0
For the best Lettuce	0	0	6
For the six best Turnips	0	0	6
For the 12 best Gooseberries, all from one tree	0	2	6
For the 12 next best, all from one tree	0	1	0
For the 12 best bunches of red Currants, all from the same tree	0	2	6
For the 12 best bunches of white Currants, all from the same tree	0	2	6
For the best Nosegay or Bunch of Flowers, of various sorts, all from the same garden	0	2	6
For the next best ditto	0	1	0
For the best bunch of Roses, all from one garden	0	2	6
For the best bunch of Stocks, raised from seed, and by one gardener	0	2	6
For the 6 best Onions raised from seed	0	2	6
For the 6 next best ditto	0	1	0
For the 6 best Carrots	0	2	6
For the 6 best Parsnips	0	2	6
For the best brace of Cucumbers	0	2	6
For the next best ditto	0	1	0
For the 12 best Strawberries raised by the same cultivator	0	2	6

The Candidates must be labouring Cottagers, and the flowers and vegetables grown in the parish of Lane-end.—*J. Peers, Lane-end, High Wycombe.*

Cabul Melons.—On reading the Leading Article at p. 571 of the *Gardeners' Chronicle* for 1843, I remember being greatly surprised at your recommending to everybody who values his comfort to expel the whole race of Cantaloupes and Rock Melons as unworthy of a modern garden. Surely, said I, some of these must have behaved very badly to deserve so severe a sentence, for in my younger days a Cantaloupe or Rock Melon was esteemed a most luscious fruit; and I, for one, cannot consent to banish them altogether, until I have further evidence to prove that they are really so very inferior to the Melons of the East. I was very desirous to obtain some seed, and this season I had the good for-

tune to have my wishes gratified by a gentleman in this neighbourhood, who presented me with four pots he had received direct from his brother, an officer in the Indian army, and one of the survivors of the Cabul affair. I need scarcely say that I grew them with great care, and was not a little pleased on perceiving one of the fruit exhibit signs of approaching ripeness. On tasting it I must freely acknowledge that, notwithstanding the little partiality I entertained for my old favourites, I found there was almost as much difference between them and the Cabul Melon, as there is between a Morello and a May Duke Cherry. The fruit proved to be remarkably handsome, of an oval shape, slightly netted, and tinged with yellow precious to becoming ripe. The flesh was white, with a greenish tinge, apparently firm, but melted in the mouth like a lump of sugar. The skin was thin, and on this account the fruit as it approaches maturity requires to be narrowly watched, as it is apt to crack and shortly afterwards begin to decay. I am now of opinion that these Melons, in the course of a few years, will supersede the very best kinds that are at present in cultivation.—*M. E. H.*

Scorching Effects of the Sun.—Without entering into the present controversy as to the cause of the spots on Vine leaves, I beg to state the following facts:—Last year I was rather profuse in syringing my Vines, particularly so on two or three occasions, when a hot sun fell on the glass before the moisture had evaporated. All the leaves became more or less spotted, and to this injury I impute the imperfect colour of my Hamburgh Grapes that season. This year I have been very sparing of the syringe, especially when the sun was out. My vinery has not a diseased leaf, whilst the Grapes are as black as sloes.—*A Subscriber, Maidstone.*

COUNTRY SHOWS.

The Coppice, Nottingham.—We had long promised ourselves a visit to the Open Show of CARNATIONS and PICOTEES, which was to be held at the Coppice, near Nottingham, on the 6th inst., to form our own opinion of the flowers raised, and the style of exhibiting by the men of the "North Countrie." Accordingly, we put ourselves inside a second class carriage (though the more was singularly unpropitious), and were in about three hours and-a-half in the Derby station. We had not much time to survey these extensive buildings, as a train was in readiness to bring us forward, and after changing vehicles, and joining several florists who had arrived by the North Midland, and bound to the same destination as ourselves, we were again (after a few ejaculations and a tremendous squeak) dragged forward towards Nottingham. This distance was speedily traversed through a highly cultivated country; we caught glimpses of the "fair vales Belvoir," and "the noble Trent," as we descended the hill, at length we neared the town. The first object that caught our eye was the Castle standing on the verge of a rock, rising abruptly from the River Leen, which rolls at its base. It undoubtedly has been an ornament to the town, but now (though as a distance it is an imposing object) it presents a sad memento, with its dilapidated and scorched walls, of ungovernable rage and popular fury. We were told that there Charles I. raised his aged when about to proceed against the parliamentary forces, and a large cavity was pointed out to us as Mortimer's hole; but our's was a brief space to view the noble wreck, and, on quitting from the station house, our first question was, "the way to the Coppice?" This question we had not to repeat, for the Committee with praiseworthy foresight, had placed placards, with a large hand pointing the way, to be put up at each turn, and through the lower part of Nottingham put us much in mind of a labyrinth, still with this clue we threaded the maze to perfection, and soon found ourselves on the opposite side of the town. A good mile and a half brought us to our destination, and here we may state that we have seldom seen a situation more adapted for the purpose intended. On getting up the hill we found a large marquee erected on the lawn in front of the house, with other conveniences for the accommodation of visitors. We found many florists congregated there, who were not exhibitors, all engaged in discussing the properties, various, &c. of the universal favourite, the carnation. We noticed Messrs. Norman, of Woolwich; Orson, of Cranham, Holland, of Maddiston; Boone, of Barnsley; &c., &c. After some little delay the doors were opened, and about 12 o'clock the Judges, Messrs. Muggleston, Mart, and Beardsley, of Nottingham, with Mr. Cowper, of York, entered on their duties, and as it was supposed that it would at least take two hours to go through them, we were anxious to look round us, more especially as the Coppice comprises part of the original forest of "Merrie Sherwoode." With our host we ascended a hill at the back of the house, and there we had a most splendid view of the surrounding country to our right; at a distance of 22 miles we saw the princely castle of Belvoir, the residence of the Duke of Rutland. Stretching away to the left, the eye roved over the hills of Charnwood Forest, whilst in the middle distance the Trent glided through the valley, its silver stream glittering in the occasional sun-beams, which, despite the rough morning, struggled through the clouds. Well, indeed, could we appreciate the fertility of the "Vale of Trent," watered as it is by so fine a river. Like a panorama lay Nottingham beneath our feet, and on either side were the artisans' gardens, looking at a distance like a "giant's draught-board." We understand that there are at least 5000 of these square plots around the town; to us it was a most pleasing sight, feeling, as we do, the rational enjoyment, the fund of health, that these small gardens must afford to their possessors. On descending we found that the Judges had not yet concluded; our host then pointed out to the foot of the hill on which the house stands, "St. Ann's Well," a spring of unusually clear and cold water, and to which great sanctity was formerly attached. On the opposite hill, before the axe had devastated the forest, which covered it, stood "Bestwood Wood," once the favourite haunt of the far-famed outlaw Robin Hood. These exciting stories, told on the spot, mix with his "merrie men" conferred their magic power. Drayton in his "Poly Olbion," Song xxvii. Marginal

"From wealthy Abbots' chests and churches abundant store,
What charitable he took, he dealed amongst the poor;
Mo Lordly Bishop came in daily remembrance by,
To him before he went, but he gave something away,
The widow in distress by accident relieved,
And remedied the wrongs of many a virgin poor."

Many more the legends that could tell of the Outlaw of this ancient domain, but enough here of Robin and his merry associations, for half-past two had now arrived, and the Judges had decided on their verdict, by which Mr. Wm. Hepton, of York, won both cups, one for Picotees, and the other for Carnations, but Lodge, of Manchester, took the second prize for Picotees, and Mr. Joseph Gibbons, of Bramcote, near Nottingham, the third. Mr. Thomas Gibbons, of Bramcote, near Nottingham, was awarded the second pan of Carnations, and Mr. Fearon, of Nottingham, the third. From what we could see, the Nottingham flowers were unassisted; assistance by the time they arrived was too late for them—in fact we were informed that they were all 24 and 36 blooms. Mr. Hepton's flowers were certainly very particularly admired amongst his Picotees, Ely's Field Marshal, which, though thin for the south, is a noble flower, Mr. Grace Darling, P. P., and Green's Queen Victoria. Rose Pearson, with Wood's Queen Victoria, R. P., were also in fine state of bloom. In Mr. Thomas Gibbons's pan, Nulli Secundus, R.F.; Lord Nelson's Prince Albert, F. P., were remarkably fine; and Wilson's Fanny Irby, R.F., and Robinson's Hero of Nottingham, were all that could be wished; whilst in Mr. Pearson's pan, Barnard's Mrs. Barnard was quite a gem. Of the Carnations, the Lion of the Day (or Blonde if you like), was Ely's lovely Ann; there was, indeed, the *ne plus ultra* of Rule and Flakes, and excited universal admiration. Mapworth's True Briton was finely marked, though the flower was rather damaged: whilst those fine flowers, Ely's Mango, P.F.; Ely's Lady Ely, F.F.; Wilson's William the Fourth, F.; Greasley's Brougham, G.B.; and Ely's Jolly Dragoon, S.B., were (to use an old Derby grower's expression), "topsum." For our own part, we had a decided *penchant* for some of Mr. Lodge's flowers. His Royal *Britain*, S.B., was a first-rate flower, and must be seen to be appreciated; Ely's Caxton, C.B., was rather thin, but brilliantly marked; whilst Euclid and Beauty of Woodhouse were in extra condition, and Rob Roy and Beauty of Cradley, S.F., were as fine as could well be imagined. Amongst the losing pans were noticed the following in splendid condition:—Ely's Lord Milton, C.B.; Hufton's Patriarch, S.B.; Ely's Lady Gardiner, R.F.; Ely's Lord Morpeth, S.F.; Simpson's Marquis of Granby, S.F.; Pollard's First-Rate, P.F.; Martin's Splendid, S.B.; Brabbin's Squire Meynell, P.F.; Hufton's Rosea, R.F. We subjoin a list of the winning flowers:—*Carnations.*—1. Mr. W. Hepton, with Hepworth's True Briton, Ely's Jolly Dragoon, Hufton's Wellington, Greasley's Lord Brougham, Wilson's Wm. IV., Leighton's Prince George, Ely's Lady Ely, Ely's Lovely Ann, Ely's Mango, Leighton's Bellerophon; 2. Mr. Lodge, with Lodge's Royal Briton, Ely's Jolly Dragoon, Soorn's Bloomsbury, Ely's Wm. Caxton, Mansley's Euclid, —— Beauty of Woodhouse, Orson's Rob Roy, Wallis's Beauty of Cradley, Ely's Lovely Ann, Ely's Lady Ely; 3. Mr. J. Gibbons, with Hufton's Patriarch, Hales's Prince Albert, Ely's Lord Milton, Greaseley's Lord Brougham, Ely's Volunteer, Orson's Rob Roy, Pullen's Queen of England, Greasley's Village Maid, Millwood's Premier, Squire's Meynell. *Picotees.*—1. Mr. W. Hepton, with Gidden's Vespasian, Ely's Grace Darling, Ely's Field Marshal, Ely's Dr. Horner, Green's Queen Victoria, Keesley's Rosea, Wood's Queen Victoria, Sharp's Hector, Wilson's John Bull, Ely's Criterion; 2. Mr. J. Gibbons, with Mark Anthony, Gidden's Teazer, Nulli Secundus, John's Prince Albert, Wilson's Fanny Irby, Green's Victoria, Nottingham Hero, Venus, Miss Hunter, Boothman's Victoria; 3. Mr. Pearson, with Queen of England, Mrs. Barnard, Fanny Irby, Marcalonessa of Exeter, Pickering's Confederate, Sharp's Wellington, Derby Willow, Nulli Secundus, Field Marshal, and Hero of Nottingham.

Garden Memoranda.

Standish's Nursery, Bagshot.—To those who are desirous of studying economy in floriculture, a visit to this nursery will be amply repaid, and afford satisfactory evidence of the perfect practicability of cultivating many highly ornamental tribes of flowering plants at a cost trifling compared with the usual outlay. Mr. S. has erected a house for the cultivation of Fuchsias and Calceolarias; it is covered with light canvas, prepared with Whitney's composition. This has been found to answer every purpose desired, and especially in bright sunny summer weather, whilst the plants are growing rapidly, when a mellowed light is so necessary. Instead of a brick parapet for the frame-work to rest upon, a low wall is made of heath-turfs, which, becoming baked with the hot sun, are almost impervious to moisture, and perfectly effective in keeping out the heaviest rains. The walls of the pit in the interior of the house are also constructed of dry turfs. There are, likewise, several pits built and covered with similar materials, in which are grown Camellias, Indian Azaleas, Heaths, &c. The house is heated by a small boiler and gutters formed of paving-tiles, which, besides being cheap, occupy very little more space than an ordinary hot-water pipe, and no more fuel is required to maintain the necessary temperature during winter, than would be consumed in a glass-house of similar dimensions. Amongst Fuchsias I noticed excellent specimens of Lowryi, a small-leaved somewhat-growing variety, with very bright scarlet calyx and deep purple corolla; an improvement on Formosa Ionans, Alacritina, the pretty little Venus Victrix, Hibley's King John, and Sanguinea nivea, two varieties with the habit of Chandleri; Antagonist, a seedling of last year with a robust habit, and leaves similar to those of F. corifolia, the sepals of the flower being short and of a bright scarlet, and the rich violet petals large and neatly rounded; Attractor, remarkable for its short sepals and the large size of the corolla; Colossus is an immense flower, with the colours of the calyx and corolla very distinct; President is another superior variety, less robust growing than the last, but flowering more profusely. Many Calceolarias are still in bloom, but the flowers are much inferior in size and colour to those produced a month or two ago; sufficient, however, may yet be seen to form some idea of their respective merits, taking the advanced state of the season into consideration. Mr. S. annually raises several thousand seedlings, and has procured many varieties with well-formed and curiously marbled flowers. Of those with a cream-coloured ground variously marked with purple of different shades, Fancy, Celebration, Delicata, and Running Rein, may be mentioned as deserving of note; and Guercino, King of Saxony, Holdenians, Acme, and the Great Western, amongst those marbled with crimson on a yellow ground. It would be fruitless to attempt to convey a distinct idea of each by description, where the arrangement of the markings is almost as endless as the changes of the kaleidoscope. In the out-door department the chief attraction consists of an extensive variety of Perpetual Roses, which are flowering profusely. Among the best are a number of crimson hybrids, such as Madame Laffay, Princess Ellen, Prince Albert, Lady Fordwich, William Jesse, Queen, and Marshal Soult. Of Bourbons there is also a choice collection, many of the best of which were not flowering. Celimene, a fine pale blush, Queen, a fine salmon-pink, and Bouquet de Montmorency, were perfect masses of flower. A variety, with deep crimson flowers, called Bosse, is eminently appropriate for planting in borders, being of a dwarf growth, and expanding flowers in succession throughout the summer season. The plants all appear to be in a healthy thriving condition, and make firm wood and abundance of roots, but the flowers are generally indifferent. This may be partly attributed to the extremely dry season, and partly owing to the nature of the soil, which is almost wholly a sandy peat, retaining moisture much better than a majority of sorts, and whilst it affords a constant supply of nourishment, never exciting to excess luxuriant growth.—*Q.*

Baroness Rothschild's Gunnersbury.—The success of Mr. Mills, as this place, in his Cucumber growing, is remarkable. His base ends just now two fruit, straight as a ramrod, ribless, blackspined, with the blossom on the end, one of which was 22 and the other 24 inches long. They are grown in one of Mr. Mills's improved pits, heated by a boiler and baths furnished by Burbidge and Healy.

Miscellaneous.

Prize Roses.—We observe by the Inverness and Elgin papers that the first Prizes for Roses, both at the Inverness and Elgin Shows, were awarded to Alexander Urquhart, Esq., at Woosepark, in this neighbourhood. At Inverness for the following cut Roses, viz.:—Fulvier, Napoleon, Archduke Charles, and Desdemona; at Elgin, for Eugene Beauharnais, Napoleon, Tetbiante, Ne plus Ultra, Lady Stuart, Aurora, Madame Buteux, Archduke Charles, 29th Juillet, Madame Broon, Clara Sylvan, and Bougare. The last-named tea-scented variety is one of the most magnificent Roses ever grown.—*Forres Gazette.*

Analysis of the Ashes of Potatoes.—These consist, according to M. Vogel, of 17·5 per cent. insoluble and 82·5 soluble salts. The former consist of 9 per cent. phosphate of lime, with some phosphate of magnesia, alumina and peroxide of iron, and of 8·5 per cent. carbonate of lime, with some carbonate of magnesia; there is no silica present. The latter consist principally of alkaline carbonates, sulphates and phosphates (5·33 phosphates, 6·93 sulphates), and traces of metallic chlorides. The soda constantly amounts to 1 per cent. more than the potash.—*Ann. de Chim. et Pharm.*, xlv. p. 265.

The Hepatica.—There are many beautiful varieties of the Hepatica in M. Van Houtte's collection, at Ghent. Some are rose-coloured, red carmine, pale lilac, and white flesh-coloured, with many other tints, among which is even repeated the colour of the stamens. Each of these varieties has a different name; they are still new, and quoted at a high price in the catalogues of this fine establishment.—*Revue Horticole.*

Carbonate of Soda in the Preparation of Coffee.—M. Pleasanel states from experience, that the infusion of roasted Coffee acquires a far superior taste, and is rendered more concentrated, consequently that a much larger amount of beverage can be prepared from the same quantity of Coffee, by adding to the boiling water, just before pouring it over the Coffee, 1 gr. of crystallised carbonate of soda for every cup, or 2½ grs. for every half ounce of Coffee.—*Med. Jahrb. des Oestr. St.*, 1843, *October.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

Such plants as wall flowers this autumn may yet be well supplied with water, and occasionally with liquid manure, but all other soft plants should be watered more sparingly after this time, and it should be performed early in the day. The house may be closed early in the afternoon, even with a strong sun-heat. At this season, we consider sun-fire dispensing off, a high night temperature is not so important to them as when they are beginning to grow in spring. In dull weather slight fires may be used in the daytime, so that plenty of air may be given to the plants.

Conservatory.—Shorten the supply of water as the night temperature is a good old maxim, and more applicable to this month now than to any other, as it is generally occupied at this season with a mixed collection of flowering plants, many of which are probably stove or half-stove sorts, which require but little water in a low temperature. Cinerarias, Violets, Chinese Primrose, with Chrysanthemums, and all other plants that will flower on this side of Christmas, must be duly attended to; and such annuals as have been proved to bloom in pots in the spring should now be sown. Since, however, the practice of forcing flowers in spring has become general, these annuals have been discarded in many places, as they occupy room where better things can be wintered.

Pits and Frames.—These are now fully occupied with half-hardy plants which grow freely in such places in the autumn; the lights should be drawn off at night to let in dews, but defend them particularly from heavy showers or continuous rain; at the same time admit large portions of air, by tilting the lights at top and bottom. This is a good time to pot Camellias for blooming in the spring, and also to graft them in close frames, without artificial heat.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

It is gratifying, when so many gardeners are complaining of the unfavourableness of the season for flower gardening, to find that there are some in the country who have no cause to complain. I am, however, aware that those who speak of "present appearances" forget what their gardens were like from the middle of May until the 1st of July, which is a most unusual occasion in discussing the merits of a season. As far as my correspondence extends, and it is by no means limited, all are complaining, and I know that if the season near the metropolis has not been a "backing," I for one am not desirous of knowing what a bad season is. However, this is not the place for discussion, and when those who have expressed their opinions I may then probably be induced to reply. Scarlet Pelargoniums now require to be propagated as expeditiously as possible; some of them, where abundantly the strong growing varieties, are very liable to rot after they are put in the soil, more especially if the season be wet; for that reason it is an excellent plan to allow the cuttings to dry for a day or two after they are prepared before they are put in the ground. The foot of a south wall is an excellent place to strike the most succulent kinds. Smith's Emperor, Shrubland Star, the Globe Compactum, and Brighton Hero, are the best of the strong growing varieties. The Fragmore and Cooper's Scarlet maintain their places in some collections, and though deficient in foliage they

are very pretty blossoms; but unquestionably the finest dwarf Pelargonium in existence is that which has this season been exhibited under the name of "General Tom Thumb." It grows almost prostrate, is exceedingly rich and dense in foliage, and produces with the greatest profusion large trusses of the most dazzling scarlet flowers imaginable. I have a plant at this moment nine inches high, and six feet in circumference, studded with twenty-seven trusses of expanded bloom, and some of the trusses are five inches in diameter; and on five plants there are upwards of 100 trusses of flowers. Another fine variety is one which I got from a nurseryman in spring, under the name of "King." It is very bright in colour, the habit dwarf, and the trusses large. The Hamiltonian is also a desirable variety for bedding out. The above are the best sorts which I have met with. I have heard of better, but I have yet to see them.

Cuttings/Geraniums.—Must now be layered, either giving them a turn, or making an incision on the under side before they are pegged down. Those intended for the greenhouse may be layered in pots, and they will seldom be check from removal that is if they are gradually severed from the old plants. Give them plenty of liquid manure after they have formed roots.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Carnations.—The seed-pods of the last blooms must now be well watched, and the calyx slit down to avoid the accumulation of wet. It will be a good plan to allow them to hang downwards. Apparently this will be a good season for seed, and from the right direction given to the cultivation and impregnation of these beautiful flowers, we certainly are sanguine in soon seeing an improved breed. Many of the old varieties of Picotee will this autumn be discarded, because edges being a sad blemish. The amateur must do well to look about him for some of the newer and better varieties to supply their places. We learn from the Midland Counties that Rose Picotees, which hitherto have been looked on slightingly, are coming into favour. The only matter of surprise with us is how they have been neglected so long. Pinks.—Seed must be gathered; half of what we have this year saved will be sown immediately, and the other half next June. Shoots, slipped off and dibbled in sand and taken off, and kept moist and shaded, will root well.

Tulips.—The bed for next season's planting must be often turned, to sweeten by exposure to sun and air. The bulbs also may be examined, and any alteration made in the arrangement of the roots, according to memorandums made in blooming time. Discard all bad and inferior varieties, those with foul cups and pointed petals for ex. *Auriculas*—must be kept free from decayed leaves, and the pots regularly supplied with water. *Pansies*—Seed may still be sown. Young plants should be pricked out in beds as shrubs when any well-grown seedlings worth saving. *Dahlias.*—Thin out strong growing sorts, and pull off deformed buds as they appear.—*J. F. R.*

IV.—PINERY, VINERIES, &c.

Pineries.—It is to be regretted that we have to those who have been growing Pines over tanks have published the result of their experience. In the absence of something better, I will state what I find to be good practice with plants intended for fruiting during January and February. The tank pot must be got in readiness by putting into it a foot, and a half or two feet of fresh leaves or tan, according to the size of the pots, or the distance of the pit from the glass. I then select the plants, and shift them into pots from 12 to 13 inches wide, and one foot deep, the sides of the pots being previously well soaked, 12 holes, each about an inch and a half in diameter, and placed at regular distances. Over the drainage I place a layer of Couch grass roots, and then some turfy loam. On this I place the ball of the plant, as entire as possible; and then fill the pot up with good sound loam, without any manure, except a small proportion of flaky leaf mould. They are then plunged in the tan, or leaves, to within one inch of the rim. By February the roots will be found to be running through the holes into the bed; I then clear away the tan and rubbish round the sides of the pots, and to the whole depth of the pit, and replace it with turfy loam and rough leaf-mould. Over this I place an inch of new tan as the lower leaves of the plants will admit of, so as to bring the heat as much to the surface as possible; one disadvantage of burying the plants out and over tanks being that the heat dries pot rise freely through the soil to the surface, where the best roots should be. It will be easily seen that the use of this kind of pot has all the advantage of the turning-out system, and at the same time meets the objections of those who complain—not without reason—of old plants not sufficient room over their plants when turned out, in such cases as their not coming into fruit when expected, &c. If the weather continue cloudy, bottom, give plenty of air to the growing plants, to prevent their drawing. Success without fail with the potting of all plants requiring it.

Vines.—This damp weather will make it necessary to use every precaution to prevent the within degrees of moisture where Grapes are ripening, or ripe. Shake a little fire during the day, and give some top air. Stop all useless growths in the late houses. Do not remove the leaves of the Vines, to expose the fruit to the sun, unless they are very thick, and under the whole surface of the glass. No leaves can require removing now, if they have been properly attended to at the time of regulating and thinning the shoots as given in December.

Peach-house.—Little is required here now, except to give as much air as possible, where the lights are kept on the house, to ripen wood, necessary, and to water the trees frequently with the syringe, to keep them free from insects and dust.

Figs.—See former Calendars.

Melons.—During this damp weather, Melons will require close attention to the removal of decaying or superfluous leaves and shoots. Keep fire regularly, every day; and light a little fire, to keep up the temperature, and give air. During fine days they will require very little water now at the roots.—*W. P.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Fruit.—The present dull weather, however favourable to the destruction of the red spider, is not at all favourable for the maturation of fruit, or of ripening wood, which must be. The bunches of Grapes ought to be turned, to ripen the globes of Rice, which may be obtained at any glass-blowing establishment, and any spare lights of framing of Peach houses might now be profitably fixed against favourite Wall or Pear trees. Where wasps or flies are troublesome, the wall may be protected with gauze or thin netting; but where much attention to pinching the wood is necessary, nothing is better than covering each fruit very closely with cotton wadding. The heavy rains we have now had will prevent wasps being very troublesome for some time.

Cauliflowers.—Make arrangements to sow seed early in, about the 20th, and again in the first week in September. The first will supply a few early heads, but they will require a good deal of protection. I chiefly depend on the September sowings. Keeping them as hardy as possible during winter, and encouraging a little frost; and then, by keeping the glasses pretty [illegible] and covering up on cold nights in spring, I get the heads early as from plants sown now, besides the advantage of [illegible] over having a head starting prematurely. [illegible] depth, cultivate sown in June and July; you will find more thought of, if you can protect them during winter.—[illegible] sorts of Broccoli. *Lettuces.*—Sow now and at the end of month for winter and early spring supply. For this purpose, the Brown Dutch and hardy Hammersmith are the best. *Cabbages*, the black-seeded white, and the different varieties of the Brown Bath, are the best for the varieties. A short-stemmed variety of the latter, sent out by the Messrs. Lane, is the hardiest for standing the winter, and the longest in running to seed in the summer that I have met with. Keep planting out succession crops. *Carrots.*—Sow a small bed now and at the end of the month for drawing young in winter and spring. *Mushrooms.*—Keep collecting horse droppings and spawn-dung, and get them dried as well as you can for beds in sheds, or houses. Where shed or house-room is deficient, and there is a scarcity of material for large beds in winter, it will be a good plan to make a slight bed or two in a sheltered place now. For this purpose nothing is preferable to the bed formed of dung from an old lining in rather a dry state. If built in the ridge form, from two to three feet in width at bottom, and the same in height, and firmly beat together and defended from heavy rains, it may be spawned, earthed, and tiered, before a larger bed could be safely covered in. This is rare weather for field Mushrooms, but many gentlemen object to their going to their table; and this is no wonder, when one sees the poisonous rubbish there is often in dangerous proximity.—*W. P.*

VII.—COTTAGERS' GARDENS.

About this time in favourable seasons the cottage garden becomes an object of interest and beauty. Many of the gayest ornaments, such as Hollyhocks, Dahlias, Lobelias, &c., are now in perfection, and will require some attention. All erect growing plants should be tied up so as to prevent them from being broken in stormy weather. In doing this, however, they should not be bundled together so as to disfigure them by giving them a stiff and formal appearance; on the contrary, the stems and branches should be kept as much as possible in their natural position, and they should be tied so as to conceal the stakes that support them. Continue to keep any fruit-trees that are trained against the walls neatly fastened in, as by this means the wood gets better ripened, and the fruit receives a greater supply of light and air. Vines should be regularly attended to; thin the bunches, and regulate the shoots, stopping back all the laterals to one joint. Where those formerly stopped have made a second growth, they must be shortened back as before. If the weather is favourable, a small patch of Onions had better be sown during the week on some rich, light piece of ground, for winter and spring use. The White Lisbon being very hardy, is a good sort for the purpose. Any ground becoming vacant, by the removal of other crops, may still be planted with winter Greens. If a small quantity of Broccoli is planted about this time, or a little later, it will form a succession to the main crop, and will be found very useful. A bed of Carrots may also be sown now for use next May. Last year I made two sowings of Lettuces, one on the 20th of August, the other on the 15th of September; both sowings did well; the latter came into use about a month later than the first sowing, and formed an excellent succession. If a small quantity of Stock seed is put in now, and the plants carefully taken up and potted when they have advanced a little in growth, they will be useful for ornamenting either the window or flower border in spring. They may be preserved over winter with very little protection. If a stock of Verbenas, Petunias, Scarlet Pelargoniums, and such other showy plants as are readily propagated can be kept over winter, cuttings of them should now be got in. If inserted about this time into a light sandy soil, covered with a hand-glass, and shaded from the sun, they will soon become well rooted, and be in good condition for standing the winter before it arrives.—*J. M'H.*

State of the Weather near London for the week ending Aug. 17, 1844, as observed at the Horticultural Gardens, Chiswick.

Notices to Correspondents.

Books.—*A. Z.*—London's "Encyclopædia of Plants" refers to garden plants as well as wild ones, and is most useful for the former. Lindley's "Synopsis" will probably answer your purpose best. British Ferns are not generally grown for sale, but the London nurserymen can any of them obtain such species as are buyable.—*Maidstone.*—"Howitt's Rural Life in Germany," and "Murray's Handbook for Germany." We are not acquainted with such books for the Channel Islands. It is impossible to say how much cheaper these countries are than England. All depends upon the way of living. They are, however, very much cheaper.

Carnations.—*An Amateur.*—Good general directions for the cultivation of the Carnation will be found in the 19th No. of the "Florists' Journal," in Wakeling's "Florists' Guide," and in other Floricultural publications.*—*S. H.*—Refer to vol. i. p. 440; vol. iii. p. 191, and you will find the information you require.*

Carnations and Picotees—*H. H.*—We recommend you the following sorts:—*Scarlet bizarres*: Twitchett's Don John, Headley's William Cobbett, Ely's Lord Durham, Strong's Duke of York, Willmer's Conquering Hero, and Ely's Lord Rollington. *Crimson bizarres*: Puxley's Prince Albert, Hyde's Duke of Bedford, Wakefield's Paul Pry, Holmes's Count Paulina, Cartwright's Rainbow, and Mansley's Robert Burns. *Scarlet flakes*: Addenbrooke's Lydia, Chadwick's Brilliant, Willmott's Hero of Middlesex, Greaseley's Mary Anne, Wigg's Earl of Leicester, and Wilson's William IV. *Purple flakes*: Mansley's Beauty of Woodhouse, Pollard's Field-Rider, Millward's Premier, Willmer's Sibsmaster, Elis's John Wright, Eyre's Mungo. *Rose flakes*: Brooks's Flora's Garland, Wilson's Harriet, Greaseley's Village Maid, Pearson's Madame Mara, Willmett's Endymion, Dutton's Duke of Wellington. *Picotees*, purple edged: Kirtland's Princess Augusta, Dickson's Trip to Cambridge, Groom's Queen Victoria, Wilson's Pluperfect, John's Prince Albert, Bennett's Purple Perfection. *Red edged*: Chadwick's Sarah Jane, Widnall's Isabella, Hanger's Duke of Wellington, Barton, and Gem. *Rose edged*: Garratt's Lady Hardy, Willmer's Princess Royal, Bateman's Miss Bateman, Chilver's Queen Victoria, Baker's Eliza, and Turnpenny's Bridget.*

Ranunculus.—*A. G.*—The best general means of giving yourself a stock of Ranunculus is by putting a little soot at the bottom of small garden-pots, which should be supported on bamboo-sticks; and by burying about roots of withered Hemlock or Beans, shelter for these the insects will enter. They should be examined daily, and destroyed. Although you may not be able to extirpate them entirely by this means of being a diligent insect, you will thin their ranks very much.*

Cats.—*W. K. W. L.*—I cannot justify killing the cat any more than he did the dog of another. If, however, in the case in question, the cat were seen in the act of killing or attempting to destroy a pigeon, it might be destroyed. *W.*

Exhibitions.—*A Subscriber.*—Any amateur who wishes to offer for 20 varieties of greenhouse plants, to any public Exhibition of flowers, &c., I would be glad to assist at the person exhibiting to include in the number one Achimenes longiflora and one *A. grandiflora*, or two varieties of any other kind of plants.* We answer yes.

Fleckiness.—*An Old Subscriber.*—We may say that Elder-flower-water or Bean-flower-water will remove them; but we have not tried either with the Peach.

Grafting.—*Pen.*—We suppose you allude to these lines—

"More wondrous change, than Apples grow on Pears,
The genius of Plum varieties Cherries bears."

This is true; but Apples do not grow well worked on Pears. The rule that like only can be grafted upon like, is not here infringed, for similitude does not signify identity.

Insects.—*Entomologist.*—Your pupæ of the Emperor moth has been infested with parasites, but as they have all hatched, it is impossible to determine the species; neither can we give you the name of the spider unless you send a specimen. *R.*—*L. T.*—The subject is too difficult to decide upon without repeated examination upon the spot. All we can do is to offer to tell you what the insects are if you detect any, and will send as specimens, protected from pressure; should you succeed. It is, however, improbable we shall find the red spider is the cause of the mischief. *R.*

Layering.—*A. B.*—These may be struck from cuttings of the young wood put in about the end of August or beginning of September. They should be put under a hand-glass in a shady, rather damp situation, and treated like the common China Rose, when it is struck from cuttings.

Local Horticultural Societies.—*Stock.*—Much obliged. We will notice this matter next week.

Mildew.—*A Constant Subscriber.*—We should say that your Peach fruit is attacked by disease in consequence of damp and cold. More sun and air would, in that case, be the remedy. You will easily judge whether this is likely to be the cause. The fruit is more often than not [illegible]

Names of Plants.—*M.*—Rescue-like.—*An Amateur.*—Eutoca viscida.—*S. W.*—Epipactis latifolia.—*A Lady.*—By no means Hunter Elegans, but Verbena melanora, or some such miserable species.—*W. W.*—Your Rose appears to be the Yellow Christ.—*Jemima.*—Your Calceolaria is Myosotis.—*W.*—Alstromerias next week.—*J. M. W.*—Corydalis umbilicha, not lutea.—Veronica verna apparently, if not, we will say so next week.—*K. L.*—It is impossible to name fragments. The leaves may have belonged to a Sorbus.

Names of Fruit.—*R. N.*—[illegible] or Cherry Plum.

Pear.—*John Horefall.*—Your [illegible] granulate of tough lining, is the Sugar Pear. [illegible] can most probably supply it. It is the Poir sans Parchemin of the French.

Pelargoniums.—*C. G.*—The following are the principal sorts with sweet-scented leaves:—Citriodorum, Prince of Orange, Emily, Fair Ellen, Bagshot Park, Citronella, rose-scented, and the balm-scented.*

Pomegranate.—*C. Thurgood.*—We are acquainted with your Pomegranate, but only from Chinese drawings. It is a fine thing when it flowers, and we congratulate you on possessing it. The Chinese have specific botanical varieties of this plant. It has no name that we know of.

Transparent Varnishes.—*J. H.*—Your letter is an advertisement.

Miscellaneous.—*F.*—Hedge-mustard.—Broccoli and cream cabbage deserve [illegible] column.—*Alnwick.*—There is no objection to having your stove to face any south east.—*M. Soul.*—The Ash is a mere common tree of the common kind, and of no importance.—*T.*—Pinguicula.—Not seeds at all; but flowers of the Blue Meadow.—*An Amateur.*—Flower-seeds can be obtained from the Horticultural Society's Garden only by members.—*Zeta.*—A young man who wishes to enter the Chiswick nursery, Garnons, should proceed by making application to the gardeners.—*G. Nathorne.*—We recommend you to [illegible] for training up the rafters of your [illegible]

Seedling Pinks.—

Fuchsias.—*G. H. N.*—We have examined your collection of Seedling Fuchsias, they are generally pretty, but are not equal to the sorts generally in the florist inclinations. No. 2 is the prettiest, this arises from its having so much green in the sepals.*—*Greens-wic.*—From your blooms being put in a box without anything [illegible] there they were completely crushed up by the time they reached us.

Lobelias.—*A. Verschaffelt.*—Neither fine, with dingy purple, nor fortuous, with rose-coloured flowers, are showy enough for England. *B. marginalis* is the [illegible] with deep lapis lazuli blue flowers, the size of *L. syphilitica*, and a pair of clear white stripes in the middle of the lower lip. We recommend you to propagate this dear.

Pansies.—*C. B.*—There are several Pansies in cultivation superior to No. 1, the eye of which is not good, and the centre wants clearness; 2 is a promising flower, being well formed, flat, with the colours clear and distinct.*

Pelargoniums.—*W. G.*—Your seedling scarlet is very brilliant in colour; it depends entirely upon the habit of the plant whether it is a desirable variety for cultivation.*—*An Old Subscriber.*—Your seedling, Miss Jane, pure and substance; it is very pretty in colour and marking.*

Picotees.—*G. H. N.*—Your Picotee named *Lizzie Scarlet* is a showy flower, the white good, and colour bright; it will make an excellent border variety, but it is not sufficiently good for a stand.*

Petunias.—*W. G.*—Your seedling is a pretty delicate pink flower, but it possesses no distinct quality to recommend it for general cultivation.*—*J. J.*—The stake by which your specimens arrived rendered it impossible for us to form an opinion of them; they require to be pickled up in something cheap. Must be easily procured, as [illegible] as good a specimen as any we know.*—*Anonymous.*—Seedlings, all common in colour and character, and not differing from the sorts generally [illegible] cultivation.—*A. E.*—None seedling is a well-formed, and very pretty flower, blue-lilac veins upon a French white ground; we have seen varieties similar to your specimen, raised this season and still [illegible]—*O. S.*—[illegible] your specimens, Nos. 2 and 3 are not sufficiently distinct from the old sorts generally cultivated; No. 1, a brilliant crimson, and 2, crimson with a tinge of purple, are both good varieties; 3, but [illegible] gold flowers with dark carmine, and dark lakes and veins, but they are too much alike, and bear too great a resemblance to others; 4, a good white, with lilac-purple tube; 5, dark, rather light pink, with strong veins; 6, very large petals, with deep blue tube slightly veined; the three latter flowers, 5 and 6, are desirable flowers of good texture.—*H. S. S.*—Thank you for the blooms; the spotting was not sufficient to make the former specimens.

Rhizos.—*A. Verschaffelt.*—Your seedlings are very inferior to Van Houtte's, and are not at all desirable additions for the English market. Mingling the pale blue flowers, with a white eye; a purple in a very few [illegible] pale, and dappled flowers part-coloured purple, producing [illegible] flowers, with a pale eye, and other [illegible] the last, not worth notice.

Verbenas.—*W. G.*—Your seedlings are varied in tint; it opens of a rose-colour; the edge of the flower fades from exposure, leaving the only colour round the tube, only from the centre [illegible] colour. We consider the flowers not attractive.*

* An unusually many communications have been received too late.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are likely to be carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several eminent Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. remuneration for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London, and is brought to the market.

Wm. Newcomb, 11, Knob-lane, Fenchurch-street.

SEED WHEAT.—Any one desirous of purchasing Seed for next year is invited to inspect the two varieties of WHITE, SQUARE-HEADED and MORTON'S RED STRAW, WINTER, the seed of which are now growing on WHITFIELD EXAMPLE FARM, THORNBURY, GLOUCESTERSHIRE.

The present is the only season of the year when the value of any variety of Wheat as Seed can be ascertained by inspection; for, if the examination of a mere sample of the grain, which can be seen at any time, be nearly conclusive as to its quality in the eye of the baker (see *Ag. Gazette*, No. 6), it is entirely so as to the productiveness or habit of growth of the variety to which it belongs. These points, which are of the highest importance in the eye of the Farmer, can be ascertained only by an examination of the growing plant when in full ear. Price, 5s. per bushel. JOHN MORTON, Whitfield, Thornbury.

The Agricultural Gazette.

SATURDAY, AUGUST 17, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Tuesday, Aug. 20 Agricultural Imp. Soc. of Ireland.
Thursday, Aug. 22 Agricultural Imp. Soc. of Scotland.

FARMERS' CLUBS.

Aug. 19 Huntingdon. Aug. 21 Gloucester.
„ Marlborough.
„ Shrewsbury.

Among the various existing means of increasing the agricultural produce of the country none is so simply or palpably efficient as that which consists in THE REMOVAL OF USELESS HEDGEROWS. Much may be added to our produce of grain and even of meat also, by the breaking up of second-rate old pastures, but this must be preceded by the breaking up of the firmly-held and long-cherished opinions of the majority of English landowners—much may be added to it by the systematic attention of landowners to the drainage and permanent improvement of their estates—and doubtless the fertility of much of the land now in cultivation may be increased to a considerable extent by the adoption of a better system of agricultural management; but in the way of all these plans lie difficulties, arising from prejudice and want of capital. The removal of useless hedgerows, on the other hand, is a mere act, requiring no surrender of prejudice, and so far from being expensive it would generally be an immediate source of revenue to the proprietor. Its consequences, also, are certain—they arise from the positive addition of acres of first-rate quality to the previous extent of cultivated land.

This source of additional agricultural produce, for which there is great need, considering the rate at which mouths requiring it are accumulating, is capable of yielding it more abundantly than might at first be thought. In the reports of Whitfield Example Farm, by Mr. Morton, we are informed that about 28 acres out of an estate of 260 acres, were actually occupied by hedgerows. Now, in addition to the mere uselessness of this extent of land so occupied, an estimate must be made of the injury done by these hedgerows to the land surrounded by them before we can determine the amount of good to be effected by their removal. And if the first item in this account equals in value 10 per cent. on that of the whole estate, when we add to it the injuries arising from the souring and mildewing influence of hedgerow shelter, from the harbour they afford for all sorts of vermin, vegetable as well as animal, and from the insuperable hindrance they place in the way of any system of improved management, we may well estimate the annual loss sustained by the landowner in this respect to have been 14 or 15 per cent. upon the rental of the estate.

But this is an extreme instance, it may be said; "to make good your case that the removal of hedgerows would be the means of increasing agricultural produce to any important extent, you must bring forward the statistics not of individual farms, but of whole parishes." Well, then, we have before us a pamphlet that gives us just the kind and quantity of information that is desired.* We extract from it the following Table descriptive of the inclosures in 10 Parishes of South Devon:—

Name of Parish.	Total Acres in the Parishes.	Miles of Hedge in the Parishes.	Acres occupied by Hedges in the Parishes.	Per Centage occupied by Hedges.	No. of Inclosures in each Parish between	½ and 1 acre.	1 and 2 acres.	2 and 3 acres.	3 and 4 acres.	4 and 5 acres.	5 and 6 acres.	6 and 7 acres.	7 and 8 acres.	8 and 9 acres.	9 and 10 acres.	10 acres and upwards.	Total number of cultivated Inclosures in Parishes.
Stoke Fleming	2,000	88	264	13		338	268	96	56	34	24	16	8	6	2	2	854
Dittisham	2,000	88	264	13		338	268	96	56	34	24	16	8	6	2	2	854
Blackawton	3,000	132	396	13		428	338	120	70	42	30	20	10	8	2	2	1070
Strete	2,000	88	264	13		284	224	80	46	28	20	14	6	4	2	2	710
Stoke Gabriel	3,000	132	396	13		428	338	120	70	42	30	20	10	8	2	2	1070
Berry Pomeroy	3,000	132	396	13		428	338	120	70	42	30	20	10	8	2	2	1070
Totnes	2,000	88	264	13		284	224	80	46	28	20	14	6	4	2	2	710
Harberton	3,000	132	396	13		428	338	120	70	42	30	20	10	8	2	2	1070
Ashprington	2,000	88	264	13		284	224	80	46	28	20	14	6	4	2	2	710
Cornworthy	2,000	88	264	13		284	224	80	46	28	20	14	6	4	2	2	710
	24,000	1056	3168	13		3405	2691	952	557	335	238	168	80	60	20	20	8526

Here we see nearly 8000 inclosures in an extent of 37,000 acres: they must have averaged about 4½ acres apiece; and the hedgerows dividing them occupy nearly 3000 of those acres—7½ per cent. on the whole extent; they must have been as nearly as possible a perch wide throughout. Now one-sixth of this width is sufficient room for a well-kept fence, and one-third the length of hedgerow would inclose the land in fields of a sufficiently small size, so that, of the 2642 acres in these parishes at present occupied by worthless brambles, nearly 2500 might be made available for cultivation, or about ⅓ of the whole extent. Now if only one-sixth part of England was thus covered with hedgerows, their removal and the substitution for them of good fences, would amount to the addition of another county to the extent of our cultivable land.

This pamphlet by Mr. Grant, of Exeter—a contribution to the statistics of this important subject—the first, we believe, that has appeared on the evils of overgrown hedgerows, will well repay an attentive perusal. We extract the following paragraph as illustrative of the general argument.

"The evils of the present system of dividing farms, general over this and great part of the neighbouring counties, may be thus summed up. The hedges occupy in some cases fully 10 per cent., but on an average of these ten parishes, 7½ per cent., or one acre in fourteen: they shade and injure at least half as much, most persons, landlords as well as tenants, whose opinion I have asked, say, *quite* as much more: they harbour birds and vermin which injure the crops; and that this is no small evil any one may satisfy himself, by going into a field just before harvest. They are nurseries for weeds: they prevent that free circulation of air, so necessary to the healthy growth of plants as well as animals: they are obstacles to the drainage of the soil, the roots grown in them frequently choking up the drains. They are expensive to erect, as well as to keep in repair; the expense of new hedges in labour and planting being about 3*s.* 6*d.* per perch, and that of keeping them in order about 5 per cent. of the rental: the soil on each side of them is generally thinner, from the materials for making the banks being taken from it. So many small inclosures require a much greater number of gates, which have to be kept up and renewed: they cause a much greater number of small lanes and cart-tracks leading from one place to another. The damage from shade is also very much greater from those hedges which run east and west. To do the least damage, and to be of the greatest service as shelter, our most prevalent and severe winds being from the west and south-west, hedges should be made, and the long way of the fields be, from north to south, for the same reason that London lays it down as a rule in building a house, to make the diagonal line in that direction; namely, because the sun thus shines on every side of it every day. The fences being in most cases cropped, and the fields of every shape but right-angled, the labour of every operation of the farm, particularly of ploughing, is most materially increased. The parishes of Hardham and Pollimore will contrast favourably with the others in this respect. This evil is anything but a trifling one, especially when to it is added the labour caused by the roots of trees which shoot out into the fields."

* "A few Remarks on the Large Hedges and Small Enclosures of Devonshire, and the adjoining Counties." By John Grant, Surveyor and Land Agent, Exeter. Longman and Co.

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

(Continued from page 510.)

Bath-stone.—This rock is the highest member of the oolitic series occurring within the limits of the district. With the exception of the lower lias, it covers a larger portion of the surface of the district than any of the other rocks to be mentioned. It is about 65 square miles in extent. Its eastern boundary is everywhere the edge of the table-land, whence the high-lands are intersected by valleys, as is before very irregular; and also in the south of the district, many hills, patches of it are in some places entirely isolated. This rock, which is an impure limestone, frequently alternates, especially in the upper part of it, with beds of clay; this is the case near Didmarton, and all along its junction with the Corn brash. It tends to split into thin slates, at an angle of 30° or 40° to the plane of stratification. The oolitic structure is not so perfectly developed in this rock as it is in a lower member of the same series. It is also generally more shelly than the inferior oolite. This renders it valuable as a building stone, rendering it from suffering so much from the weather; at the same time that it admits of being hewn for ornamental work. It is distinguished among the masses from the lower oolite, which is very soft, by the mark of weather-stone.

Agricultural Character of the Bathstone.—The general appearance of this formation, at least the contrast which it presents to the others which are to be mentioned, is due, probably, as much to the climate and aspect of the country, as to any difference in its geological character. The level of the district here being 500 feet higher than that of the vale below, it is not only much colder, but is more exposed to wind from every quarter. Its appearance is certainly bleak, compared with the richness of the vale. The land is almost entirely inclosed by stone walls; very little hedgerow timber exists. A few stunted Ash-trees, or here and there a Beech or Sycamore-tree, are all that are that are to be seen. The fields are large, most of the land is arable, perhaps not above one-eighth being in pasture. The farms are generally large, varying from 300 or 400 acres up to upwards of 1000. The quantity of pasture land thus varies from 40 to 50 acres, which is sufficient to keep a small dairy. It is always placed around the farm buildings. The nature of the soil varies; it is chiefly a brashy soil, of a light-brown colour, and very shallow. In other cases it is a stiff clay. This depends on the nature of the subsoil, which, as was said, consists of alternate beds of limestone and clay. The clay is an extremely poor soil, and is productive, in common with all clayey soils, of Thorns, stunted plants of which occasionally occur in the pastures. The brashy soil is more fertile than the clay. It is in general a light soil, but when wet is liable to cling. In some spots it is what is called a sleepy soil; *i. e.* if well pulverised, it will, after rain, run together as if melted, and then it presents a surface impervious to water and air. Water will lie on such a surface; and, not only so, but the seed in the ground will hardly pierce it. Such a soil is difficult to manage. If the farmer prepare and pulverise it well before sowing, then on the first shower of rain it is injured as I have described. If he does not pulverise his soil, it is just as faulty in an unpulverised state as any other soil. There is a certain degree of dryness in which he must leave it, so that when rain comes it will break it down, without causing it to run together. Very little drainage is done on this land. The subsoil is rock, and yet the land is, in many cases, wet. The clay beds, which here and there come to the surface, render the drainage difficult. The subsoil plough it would be impossible to use on some of the lands, on other places it might be used advantageously. Where the clay and the rock join, and the rock thins out over the clay, the mixture which would be effected by the use of this implement would be productive of good. That this also is the opinion of many of the farmers, I might suppose from what I have heard said regarding the large stones lying on the surface of the land; it was stated that instead of gathering these and carting them away, it would be better to break them up small, and strew them over the surface of the clayey land. The long practice, from necessity, however, of shallow ploughing, seems to have made many farmers think that deep ploughing is injurious, and subsoil ploughing bad in principle. It is the general idea that shallow ploughing is preferable to deep ploughing, and most farmers go much shallower than there is a necessity for. The general rotation on this formation is a six-years' course:—1st, Wheat; 2d, Oats; 3d, Turnips; 4th, Barley; 5th, Seeds; 6th, Seeds. Several departures from this are made in many districts, two of them are as follows:—Wheat, Turnips, Barley, Barley, Seeds, Seeds; and Wheat, Barley, Turnips, Barley, Seeds, the last being a five-shift course, which is sometimes altered by taking Oats after Wheat instead of Barley. The fault of this system is the having two Corn crops in succession, Wheat and Barley, or Wheat and Oats. The alteration of the general system, that pointed out, and the having two Barley crops in succession, is, I should think, no improvement on it; but, although it was acknowledged that the second crop of Barley was always inferior to the first, it was stated that the seeds were always a better crop after two years' Barley than after only one. There are no leases granted on this district, and the tenant is, therefore, not bound down to any particular course of crop-
